CONTENTS.

VOLUME II. JULY TO DECEMBER, 1866.

- Aberdeen University pass-list, 228
Abscess of the prostate, Mr. Hamilton on, 613, 637; of liver, Dr. Lyons on, 641
Absolon *v.* Statham, case of, 518, 550, 626
Accidental deaths from injuries, 43
Aconite, cases treated by, 121
Actions against medical men, 19
Adams, Mr. on double psoas abscess, 113, 131
Adrian, Dr. cases from the MS. of Dr. MacEvoy, 300, 431
Æsophagus, epithelial cancer of, 99
Agnis, Dr. obituary of, 132
Alcohol, influence of, on animal temperature, 283
Amputation of the leg, Dr. Crauford on, 248; of foot, 387; improved flap, 449
Anæsthesia, local, Dr. Richardson on, 11, 243; a dental insulator for, Mr. McClean on, 34; by mixed vapours, 125
Aneurism, axillary, case of, 97; popliteal, treated by ligature, 617; of ascending aorta, 640
Ansell, Dr. obituary of, 131
Anthrax, treatment of, 72; Dr. Richardson on, 628
Aorta, irritable, Dr. Lyons on, 35; injury to valves of, Dr. Foster on, 615; aneurism of ascending, 640
Apothecaries' Hall of London pass-lists, 29, 58, 111, 143, 168, 191, 218, 261, 286; regulations of, 274, 319, 349, 379, 424, 500, 554
Appointments, 50, 90, 143, 192, 219, 239, 262, 286, 319, 349, 378, 404, 425, 451, 477, 479, 500, 531, 554, 581, 607
Arachnitis, cerebro-spinal, Dr. Little on, 7; at base of brain, 10, 69; Dr. Hayden on, 439
Armstrong, Dr. letter on Poole Fund, 257
Army Medical Department, letter on, 52, 57, 167; regulations, 267; regulations of pay, 211; list of cadets, 212; in United States, 346; promotion in the, letter on, 530, 581
Atrophy, muscular, from spinal disease, 70
August, 1866, meteorology for, 281
Banon, Dr. introductory at Jarvis-street Hospital, 503
Barlow, Dr. obituary of, 450
Barwell, Dr. introductory at Charing-cross, 322
Beamish, Dr. on cholera treated on the antidotal plan, 481, 575
Bedford's cod-liver oil, 339
Belcher, Dr. on porrijo, 574; on porrijo, 626
Benson, Dr. introductory lecture at City of Dublin Hospital, 557
Bennett, Dr. John Hughes, address in medicine, 218
Births, deaths, and marriages, 30, 60, 112, 143, 192, 218, 239, 262, 286, 319, 349, 380, 404, 425, 451, 479, 531, 554
Bishop, Dr. on artificial support in deafness, 627
Bite by a dog treated by nitric acid, 10; from insects, inflammation from, 95
Blood, action of oxygen on, 14; poisoning of, 245, 342
Bouchut, M. on paralysis of the sixth nerve, 151, 306; on encephalitis, 353
Bowman, Mr. address in surgery, 193; leader on, 229
Brain, tumour of, 13; sclerosis of, 43; defective corpus callosum, 284; Dr. Ogle on softening of the, 297, 566, 634
Breathing space for paupers, 599
British Medical Association, proceedings of,
British Association proceedings, 243
Burns, treatment of, 256
Calabar bean in cholera, 267
Cambridge University regulations, 269; natural science tripos at, 643
Cæsarian section, two cases of, 42
Cancer, epithelial, case of, 68; Dr. Broadbent on, 245; of temporal bone, 412; of the cervix uteri, 440
Cancrum oris, Dr. Stevenson Smith on, 61
Carter, Dr. case of ovariectomy, 248
Cataract, extraction of, 222; suction instruments for, 422
Cattle plague, disinfectants, 21, 81, 135, 164; treated by injection of artificial chyle, 25; Dr. Madden's papers on, 31, 62, 270, 301, 372, 385; in Ireland, 78
Change of type in disease, on, 253, 317, 343, 378
Charitable institutions, rating of, 45
China, mortality of troops in, 237
Chloroform, treatment of cholera by, 228
Cholera, hospitals, 22, 127; progress of, 24, 44, 108, 201, 230, 258, 313, 338, 368, 392, 412, 414, 417, 471; on, 109, 111, 130, 140, 153, 189, 226, 272, 281, 304, 404, 522, 540, 566, 624, 645; Dr. Little on, 119; latest news of, 148; in London, 159, 180, 202, 222; are we prepared for, 161; eliminative treatment of, 165; report on, 167, 255; Dr. Ross on, 170; in the London Hospitals, 176, 202, 250, 271, 304, 339; blue mist, 190; English, 174, 203; fund for, 217; treated by sulphuric acid, 228; treated by chloroform, 228; deaths of medical men from, 232, 123; cases of, 233; the depressing passions in, 254; Rev. S. Haughton on, 260; Dr. Patterson on, 246; Dr. Twiss on, 246; calabar bean in, 267; the germs of, 312; the dietetic treatment, M.A.B. on, 317; in merchant vessels, 418; contagiousness of, 421; Dr. Reid on, 432; typhoid fever terminating in, 437; Dr. Daldy on, 459; treated by venous injections, 435, 464, 507, 539, 573, 589; the Mansion House Fund, 474; Dr. Beamish on, 481, 575; Dr. Cummins on, 535; Dr. Meldon on, 538, 577; the rice-water ejections of, 541; Dr. Leney on, 549; prevention and treatment of, 622
Chyle, artificial, treatment or rinderpest by, 25
Civic honours, 646
Clarke, Dr. on embolic phthisis and tubercle, 611, 633
Clavicle, entire destruction of, 12
Club, the Medical, 314, 379, 494; letters on, 134, 449, 548, 631; proceedings of, 490
Collis, Dr. M. H. on femoral hernia, 65
Contagious Diseases Act, 275
Cork Poor-law Guardians, the, 86, 259
Coroners and their witnesses in Dublin, 553
CORRESPONDENCE.
Mr. Griffin on the Poor-law Association, 21, 134, 164
"M.D." on cattle plague disinfectants, 21
"A Dispensary Doctor" on salaries, 222
Dr. Cunningham on cholera Hospitals, 22
Mr. Phelan on Poor-law statistics, 23
Dr. Fowler on the Griffin testimonial, 23, 53, 84, 107
The treatment of delirium tremens, 52
"One of the Above" on the Army Medical Department, 52
Mr. Langley on medical representation, 53

 Mr. Fitzpatrick on fees for attendance on the families of medical men, 318
 "H. R." on the field hospitals of the Prussian army, 341
 "M.D.T.C.D." on blood poisoning, 342
 Dr. Armstrong on the Poole fund, 343, 371
 Dr. H. Kennedy on the change of type question, 343
 Dr. J. W. Swan on malpraxis by a bone-setter, 343
 "J. M. L." on the effect the mind of the mother has on the fœtus in utero, 343
 "W. C. C." on the recovery of medical accounts, 343
 Dr. Lane on medical fees in Nova Scotia, 372
 "M.D." on medical curricula and their uses, 371
 The change of type question, 378
 Dr. Sutton Page on a new apparatus for fractures, 419
 Dr. Nicolls on educated midwives, 420
 Mr. Day on Ozone as a sanitary agent, 421
 Dr. MacCormac on the prophylaxis of Asiatic cholera by means of dilute of sulphuric acid, 421
 Dr. Brassington on the contagiousness of cholera, 421
 "A Chemical Student" on the elements of mutton suet, 422
 Dr. Davey on suction operations for Cataract, 422
 On the present system of medical education and examination, 447
 Mr. Tichborne on carbolic acid for disinfection, 449
 "An intending member" on the medical club, 449
 Dr. Thompson on an improved flap-amputation, 449
 Smith's test for ozone, 449
 Dr. Thompson on the honoris causa of the Queen's University, 475
 The late poor-law investigation at Donnybrook, 475
 The matriculation examination of the Queen's College, Galway, 475
 "Paterfamilias" on promotion in the army medical department, 530
 A candidate for the office of coroner, 530
 Mr. Smyly on Holt's instrument, 530
 Jones' chart, 530
 Dr. Kidd on the reduction of dislocation, 530
 "M.D." on the appointment of a medical inspector, 530
 Letters of "J. K." and "Aliquis," 548
 Mr. Reynolds on oxalate of iron, 549
 Dr. Leney on the treatment of cholera, 549
 Dr. Hearne on yellow fever on board the *Atrato*, 580
 Dr. Rodgers on toxicological discrepancies, 580
 "Ostentation" on Garibaldi's characteristics, 581
 Mr. Richardson's reply to Mr. P. C. Smyly.—Perrève's stricture dilator, 602
 J. H. Chapman on epistaxis, 606
 C. Robinson on a case of Asiatic cholera treated by large doses of calomel, 606
 Dr. Lory Marsh on the medical club, 631
 Dr. Barker on epistaxis, 631
 Letter of a "Miser," 631
 Mr. Hearne on yellow fever, and quarantine, 650
 Mr. Ledwich on dislocation of the thumb, 651
 Mr. Wilson on Hunter *v.* Sharpe, 651
 Corporation, Dublin, proceedings of, 553
 Craniotomy, Dr. O'Flynn on, 301; the forceps in, Dr. MacEvers on, 386; Dr. Griffith on, 428
 Crauford, Dr. on amputation of the leg, 248
 Cummins, Dr. on cholera, 535
 Cunningham, Dr. on eczema, 95
 Cyclops, letter of, 81
 Cystoid kidney, M. Koster on, 334, 364
 Daldy, Dr. on cholera, 459
 Delirium tremens, treatment of, 52
 Delfoid muscle, an artificial, 146
 Denny, Mr. prosecution of, 476
 Dental insulator, for anæsthetic operation, Mr. McClean on, 34
 Dermatology, Dr. Belcher's papers on, 574, 626; study of, in England, 578
 Dewar, Dr. on the uses of sulphurous acid, 247
 Dialysis, new discovery in, 155
 Diarrhoea, Dr. Lyons on, 203, 226
 Dickson, Dr. scurvy in merchant navy, 3
 Diseases Prevention Act, the, 238, 275
 Disinfectants, in the cattle plague, 21, 81, 135, 164; steam as, 155
 Dislocation of entire clavicle, 12; of the thumb, 651
 Dispensaries as schools of medicine, 51, 133
 Drennan, Dr. address to Ulster Medical Society, 528
 Drugs, state of the trade in, 18, 83, 134, 208, 277
 Dublin, health of, 212
 Durham University, regulations, 271
 Dwani, Dr. case of, 256
 Dyspeasia, Dr. Forbes, lectures on, 91
 Dysentery, chronic, Dr. Leach on, 246
 Earth-closets *v.* water-closets, 394
 Eczema, treated with carbolic acid, 35;
 Dr. Cunningham on, 95; M.D.T.C.D. on, 488
 Edinburgh Medical School, sketch of teachers, 19; museum of science, &c., 20
 Edinburgh University, athletic games, 21; Professor Christison on, 177; pass list, 190
 Edinburgh Colleges of Physicians and Surgeons,
 EDUCATIONAL REGULATIONS OF COLLEGES, SCHOOLS, AND HOSPITALS.
 University of Oxford, 268
 University of Cambridge, 269
 University of London, 270
 University of Durham, 271

 University of Glasgow, 293
 University of Aberdeen, 293
 Faculty of Physicians and Surgeons, Glasgow, 293
 Royal College of Physicians, Edinburgh, 294
 Royal College of Surgeons, Edinburgh, 294
 Schools of Medicine, 295
 The medical students daily and hourly hospital and class guide, and tabular list of the physicians, surgeons, teachers, fees, and days of operations at the hospitals and medical schools of the metropolis, 278
 Elephantiasis Arabum treated by ligature, 282
 England, vivisection in, 256
 Emphysema, Dr. Lyons on, 252
 Epilepsy, the treatment of, 173
 Epistaxis, Dr. Ballard on, 542; letter on, 631
 Epithelioma, of lip, 9; of œsophagus, 99
 Epulis, case of, 97
 Erythroxylon coca, on, 28
 Examination, Queen's University, papers, 27, 348, 376; visitation of, 29, 157, 492; Dublin University papers, 88, 142; Royal College of Surgeons in Ireland, papers, 497
 Fees, medical, 77, 108, 209, 259; for attendance on medical men, 278, 318; 646, 650
 Fever, typhoid, terminating in cholera, 437; typhus treated by tea, 462, 486; yellow, at Southampton, 547, 598; at Demerara, 645, 651; and quarantine, in Nova Scotia, 370
 Fincham, Dr. introductory at Westminster Hospital, 354
 Fistula, urinary and anal, Dr. Paul on, 116
 Fœtus, extension of, within the uterus, 4; influence of the mother's mind on, 343
 Foot, Dr. A. W. cases reported by, 9, 35, 68, 97

FOREIGN MEDICAL LITERATURE.

Entire dislocation of the clavicle, 12
 W. Koster's two cases of tumour of the brain, with remarks on the connexion between cerebral tumours and affections of the retina and of the optic nerve; translated by Dr. W. D. Moore, 13
 Action of oxygen on the blood; translated by T. W. Hime, 14
 F. Z Ermerins on irradiation on symmetrical parts of the opposite side; translated by Dr. W. D. Moore, 37
 Dr. C. van Wicheren's case of epithelial cancer of the œsophagus, with perforation of the aorta; translated by Dr. W. D. Moore, 99
 M. Bouchut on the diagnosis of symptomatic and essential paralysis of the sixth pair of nerves, by means of the ophthalmoscope; translated by Dr. B. W. Foster, 151
 Two cases of brown discoloration of the skin with morbid affection of the suprarenal capsules; translated by Dr. W. D. Moore, 305
 On uric acid infarction and congenital cystoid kidney; two cases; translated by Dr. W. D. Moore, 334, 364
 M. Bouchet on ophthalmoscopy in a case of chronic encephalitis; translated by Dr. W. Foster, 335
 C. Withusen on a case of ligature of the common carotid artery for a pulsating tumour in the orbit; translated by Dr. W. D. Moore, 514
 On the treatment of Hemoptysis with inhalations of liquor ferri sesquichlorati sesquichloridi; translated by Dr. W. D. Moore, 592
 Foster, Dr. B. W. lectures on dyspepsia, 91; translation on the diagnosis of paralysis of the sixth pair, 151, 306; on ophthalmoscopy in encephalitis, 335; introductory at Sydenham College, 360; cases of injury to aortic valves, 615
 Fracture, Colles', with Gordon's splint, 68; of frontal bone, 221; of cranium, 250, 300; new apparatus for, 420; of the upper extremity, Dr. Hamilton on, 638
 Frankland, Dr., on the source of muscular power, 541; on the rice-water ejections in cholera, 541
 Frontal bone, fractures of, 221
 Galvanism, treatment of lead paralysis by, 488; paralysis treated by, 490
 Gastein and its springs, Dr. Proell on, 32
 Glottis, spasm of the, Sir H. Marsh on, 533
 Goitre, exophthalmic, 617
 Gratuitities to public vaccinators, 599
 Griffith, Dr. case of evulsion of the umbilical cord, 147; treatment of cholera by chloroform, 228; case of face presentation, 268; on rupture of the uterus, 332; on craniotomy, 428; case of tedious labour, 485; case of trismus, 534.
 Griffin, Mr. testimonial to, 23, 53, 84, 90, 107; and poor-law reform, 51, 208
 Grimshaw, Dr. letter on the ophymograph, 208; typhoid fever and cholera, 437; typhus treated by tea, 462, 486
 Guards, officers of the, 237
 Guffroy's cod-liver extract, 126
 Gunshot wound of frontal bone, 221; of neck, 268

Hæmoptysis, phthical cases of, 122
 Hæmorrhœa, Dr. Leney on, 435; accidental concealed, 440; umbilical, 510
 Hamilton, Mr. on phymosis, 92, 114, 171; address at Richmond Hospital, 457; on abscess of the prostate, 613, 637
 Hargrave, Dr. contributions to clinical surgery, 145
 Hasting, Sir Charles, obituary of, 166; proposed memorial to, 337
 Haughton, Rev. S. on treatment of cholera, 260
 Hayden, Dr. on mitral obstruction, 5, 32; on cerebro-spinal arachnitis, 439; cases of pnesmatosis, 540
 Head, Dr. introductory at London Hospital, 323, 355
 Hearne, Dr. letters on the cholera in Southampton, 163, 209
 Hepburn, Dr. case of serotal hernia, 34
 Hernia, scrotal, with orchitis, 34; femoral, Dr. Collis on, 65; femoral, 99; oblique inguinal, 224, 283; protruding between femoral vessels, 618
 Hime, Mr. T. W. translation, action of oxygen on blood, 14
 Hinton, Mr. restoration of memb. tympani, 614
 Holt, Mr. stricture instrument, letter on, 530

HOSPITAL REPORTS.

Epithelioma in the lower lip; rodent ulcer at the eyebrow; bite in the leg from a dog; application of strong nitric acid, under the care of Mr. Porter, 9
 Arachnitis at the base of the brain chiefly, Dr. Lyon's clinique, 10
 Chronic eczema on the leg, treated with carbolic acid ointment; chronic enlargement of the tonsils, treatment with caustics, subsequent amputation with a tonsil guillotine; contraction and fibrous ankylosis of the knee-joint, under Mr. Porter, 35
 Irritable aorta, Dr. Lyon's clinique, 35
 Cases treated with hypophosphites of lime and soda, under Dr. Thorowgood, 67
 Whooping-cough cured by hypodermic injections, under Dr. Beigel, 68
 Colles' fracture treated with Gordon's apparatus; epithelial cancer of the lower lip; hydrocele of the tunica vaginalis testis, under Mr. Porter, 68
 The cholera wards of the London Hospitals.—The London Hospital; Limehouse District Cholera Hospital; Commercial-street Cholera Hospital; "Bellisle" Hospital Ship; Wapping Cholera Hospital, 176, 222, 250, 271, 304, 389, 412
 Cholera: its pathological anatomy and general pathology, Dr. Lyons' clinique, 272
 Cholera typhoid, Dr. Lyon's clinique, 304
 Stenosis with obstruction of aorta, Dr. Lyons' clinique, 333
 Case of scirrhus; amputation of the foot; case of hydrocele, under Mr. Walton, 387
 Complicated case of purpura hæmorrhagica, under Dr. Hogan, 388
 Special report on the treatment of cholera by venous injections, 435, 464, 507, 539, 573, 589
 Typhus fever, with enteric symptoms, terminating in cholera, recovery, by Thomas W. Grimshaw, M.B., 437
 Cerebro-spinal arachnitis, under Dr. Hayden, 439

Stricture of the Urethra—Forced dilatation; no blood lost; marked improvement, under Mr. B. W. Richardson, 466
 Aneurism of the axillary artery; large epulis originating in the tooth socket, under Mr. Porter, 97
 Typhoid fever; hay fever, Dr. Lyons' clinique, 98
 Case of strangulated femoral hernia, under Mr. Barton, 99
 Case of psoas abscess; wound of femoral artery, under Dr. Adams, 121
 Cases treated by aconite internally, under Dr. P. James, 121
 Cases of phthical hæmoptysis, under Dr. Hughes, 122
 Organic cardiac murmurs, disappearance of, Dr. Lyons' clinique, 123
 Stone in the bladder of a child, removal by lithotripsy; stone in the bladder of a male, lithotripsy and cure; lithotripsy in a young man, aged 18; large calculus, under Mr. Bryant, 149
 Phthisis senilis; pericarditis, autopsy; renal disease, bronchial phthisis; autopsy, Dr. Lyons' clinique, 150
 Lead paralysis treated by electricity, under Professor Banks, 488
 Hydrocele and its treatment, by Mr. Haynes Walton, 489, 507
 The London Infirmary for Epilepsy and Paralysis—Cases under Dr. Althaus, 490
 Two cases of peritoneal pneumatosis, under Dr. Hayden, 540
 Idiopathic tetanus, treatment by tobacco and nicotine, Dr. Lyons' clinique, 572
 Typhus supervening on typhoid fever, Dr. Lyons' clinique, 588
 Popliteal aneurism; ligature of the femoral, under Mr. H. Walton, 617
 "Exophthalmic goitre," under Dr. Moore, 617
 On the treatment of epilepsy, under Dr. Althaus, 173
 English cholera: Asiatic cholera, Dr. Lyons' clinique, 174
 Gunshot fracture of the frontal and temporal bones, under Mr. Little, 221
 Flap extraction of cataract; strangulated oblique inguinal hernia, under Mr. Richardson, 223
 Diarrhœa: cholera, Dr. Lyons' clinique, 226
 Superficial emphysema, two forms of, Dr. Lyons' clinique, 252
 Hernia protruding between the femoral artery and vein, under Mr. Little, 618
 Dr. Lyons' clinique, 618
 "Aneurism of ascending aorta," under Dr. Moore, 640
 Abscess of the liver; puncture of that organ, Dr. Lyons' clinique, 641
 Hospitals, cholera, letters on, 22; of Paris and London, 203
 Hughes, James Stannus, F.R.C.S., new foot-board to Dupuytren's splint, 1; clinical lectures of Sir H. Marsh, edited by, 533
 Hulke, Mr. introductory at Middlesex Hospital, 359
 Hydrocele, case of, 69, 387; Mr. Haynes Walton on, 489, 507
 Hypodermic treatment of whooping-cough, 68
 Hypophosites, cases of chest disease, treated by, 67
 Indian Army Service, list of successful

- candidates, 239; towns, sanitary condition of, 496
 Indian Medical Service, Army Staff, 599
 Infanticide, debate on, 397
 Inguinal hernia, oblique, with death after reduction, 224; with undecided testis, 233
 Insanity, causes of, 510
 International Medical Congress, 472
- INTRODUCTORY ADDRESSES.**
 St. Bartholomew's Hospital.—Mr. W. Savory's introductory address, 321

PRACTICAL OBSERVATIONS ON THE
ADJUSTMENT OF A FOOT-BOARD TO
DUPUYTREN'S SPLINT
—◆—
IN THE
TREATMENT OF FRACTURES OF THE LOWER
END OF THE FIBULA.

By JAMES STANNUS HUGHES, M.D., F.R.C.S.I.,

SURGEON TO JERVIS-STREET HOSPITAL; PROFESSOR OF SURGERY IN THE
ROYAL COLLEGE OF SURGEONS IN IRELAND; SURGEON TO THE LORD
LIEUTENANT'S HOUSEHOLD, ETC.

NOT long since I had the honour of laying before the profession a new foot-board for Desault's long splint in oblique fractures of the femur which met with general approbation. I now place before my brethren a foot-board which I contrived some ten months ago for Dupuytren's short splint in cases of fractures of the lower end of the fibula, and which I have since used with great advantage in several cases of these accidents.

The first patient on whom I tried the modification of Dupuytren's splint is a well known poor blind man of the name of Briggs, who obtains his livelihood by playing on a tin flageolette whilst led by a little dog through the streets

of Dublin. Briggs' having been knocked down and run over by a horse and car in July last, was carried into Jervis-street Hospital labouring under a fracture of the lower end of the fibula, together with rupture of the fibres of the infernal lateral ligament of the ankle-joint, and as a consequence, with eversion of the foot. The limb was placed in Dupuytren's splint (admittedly the best appliance in such a case), but it was found impossible to maintain the splint in its proper position by the ordinary means, owing partly to the helplessness of the poor blind man to assist in doing so, and partly to the constant tendency of the splint to become displaced by *ascend*. After some consideration I applied to the splint a simple lateral foot-piece made of sheet iron, presently to be described, by which the splint was not only prevented from becoming displaced by *ascend*, but the normal relations of the fibula and foot were steadily maintained throughout the treatment, and the heel was perfectly relieved from pressure—a point, as every practical surgeon knows, of great importance in these cases.

The apparatus consists, as may be seen by the accompanying woodcut by Mr. Oldham, from a photograph by Mr. Mercer and a drawing by Mr. Burnside taken during the treatment of Briggs' case, of Dupuytren's splint A A, with a lateral foot-board B, supported by two broad foot-stalks C C. On the external part of the foot-piece corresponding to the outer edge of the sole of the foot, there is a slot D, through which and the slots E E, the figure-of-eight bandage G, which extends and keeps the foot in its place, is brought out and applied in the usual manner after the conical pad H and upper roller K have been adjusted according to Dupuytren's directions. The extending force can be increased or diminished, the foot-board reversed, and the splint made to accommodate any sized patient by means of the two brass thumb screws F F, which are attached to the foot-board, and made to play in the slots E E.

The advantages of the above foot-board may be thus summed up:—

1st. The foot and fibula are steadily maintained in their normal relations.

2nd. The splint is prevented from becoming displaced by *ascend*, or in any other direction.

3rd. The heel is preserved from pressure.

4th. The extending force can with the greatest ease be increased or diminished, and the foot-board reversed.

5th. The apparatus is in no way irksome to the patient, and as it demands but very occasional readjustment, it saves the surgeon a great deal of time, trouble, and anxiety. Thus accomplishing in a very simple yet efficient manner with Dupuytren's splint even more than its distinguished inventor sought for in the treatment of fractures of the fibula.

The foot-board in question is, so far as I know, *original*—a term, however, which I have always been in the habit of using with great caution, for I well know that there are few surgical appliances which can in the present age be with truth so named, as can be easily proved by an inspection of the plates to be found in the works of Scultetus, Heister, Dionis, and other ancient authors.*

THREE CASES OF IMPACTED FÆCES IN THE POUCH OF THE RECTUM: WITH REMARKS.

By ANDREW PAUL, A.B.M.B., L.S.C.S.

Case 1.—In the summer of 1848 I attended a lady in town for spasm of the anal sphincters. I found her on the floor, with her feet elevated, and with intense bearing down at intervals in paroxysms resembling labour. Injections and aspersions, first hot, reduced down to cold from my douche bath, relieved her. On spasm subsiding, hard lumps were voided, with loud explosions of wind. Flatulence for years had been her trouble.

In 1851 I was written to, on a return of the same symptoms, more intense than in 1848. Aperients, injections did no good. I advised the passing of the finger, and if hard lumps were felt to hook them out. She did so, and succeeded—one, the size of a hen's egg, unusually hard, of a dirty chalky colour, when broken up contained a plum-stone. She declared she had not touched stone fruit for two months before.

Are the various forms of rectal diseases—to wit, piles, fissure, fistula, spasmodic sphincter, hereditary? as four members of this one family have been in my hands since 1837, constipation the forerunner with all, of local trouble. Some surgeons would divide the sphincters, yet this lady, the mother of a grown-up family, is now advanced in years, troubled only with occasional constipation.

Case 2.—I attended a young married lady, without family, in 1855. Symptoms as in the foregoing. Unlike it, there was in this case much to contend with in treatment, arising from preconceived fancies and caprices. For example, compound powder of jalap was one medicine in the list of predilections, as a remedy, quite unsuited both to constitution and to local disease. Examination of the bowel being denied me, injections alone were complied with. After two months' attendance, violent abdominal pain setting in, calomel and opium were reluctantly taken. Bearing down and frequent desire to evacuate ensued, ending in expulsive efforts quite independent of will. Never will the mother of this lady forget the evolutions of fæces, in various phases of consistency, which ensued during twenty-four hours, the lady all the while in bed, and in the posture of a labour-pain woman, quite unconscious of what was coming from her, yet resulting in complete relief.

Here was a case wherein division of the sphincters had been strongly urged by the surgeon consulted previous to my first visit, and as strongly backed by the lady's husband, as the only chance for permanent relief, yet two years ago, on my seeing this lady, occasional costiveness was then her only trouble. Incontinence of fæces is admitted to be a too frequent sequel to division of sphincters, whether for fissure or fistula, making the remedy to the patient worse than the disease.

* The above foot-board was made by Messrs. O'Neill and Thompson of Heary-street.

Case 3.—In 1839 a lady in Devonshire consulted the writer for inward piles. Pressure alone, with cold water aspersion, gave at this time, and continued to give, relief.

I append an illustration of the apparatus employed for cold aspersion, which proved so efficacious in this case. Its principle and construction is manifest.

In 1864 I attended this lady for hæmorrhage from the bowel, the forerunner of a fresh growth of piles—"buds," in short, upon a very relaxed mucous membrane. Of both she was cured at the time.

Three weeks back a fresh attack was announced, calling me into North Devon. On examination, no vestige of piles could be seen, save the outward flaps or fringes of skin, indicating the existence of foregone tumours within. On passing the finger it encountered a round impacted mass in the pouch of the rectum, hard, and as large nearly as a cricket ball. The finger encircled this mass, as the accoucheur does the head of the fetus in parturition.

Were the sphincters to be divided, a stone forceps to be passed in, and this mass to be withdrawn whole or crushed? the rough-and-ready way. No. Incontinence of fæces, hereafter, might thereby prove an annoyance greater than such occasional impacted masses. Medicine would not touch this lump, injections would not stop up a sufficient time to soften the mass, hard for them, as urgent bearing-down in every position, from the erect to the inclined, was present, with tension and tenderness of abdomen foreboding mischief.

Making the curve of the sacrum a fulcrum, the forefinger and nail a drill, this ball was broken up into four pieces, and one was hooked-out; the remaining portions came away, aided by injections, which now—not as before—kept up a sufficient time to soften and to lubricate the residue. The blasts of gas escaping after all this astonished and made ashamed this old lady, now in her 75th year.

Though the widow of an eminent surgeon, she declared "she never heard of such a thing." "They will collect again," was the warning, "unless you take care." With that the writer took his leave.

Such cases are not of every-day occurrence, even with surgeons specially devoted to rectal disease; to general readers they may prove instructive.

27, Mecklenburgh-square, London, July, 1866.

The foundation stone of the new North Staffordshire Infirmary was laid by the Prince of Wales at Hartshill, near Stoke-upon-Trent, on Monday. The town and district were quite en fête, and business was almost wholly suspended.

ABSTRACT OF A PAPER
ON
SCURVY IN THE MERCHANT NAVY.

By Dr. W. DICKSON, R.N.,
MEDICAL INSPECTOR H.M. CUSTOMS.

(Read at the Epidemiological Society, June 4th, 1866.)

THE author had been engaged during the last twenty months in a series of investigations instituted by the Board of Trade, with the view of ascertaining the origin of scurvy in various ships which had arrived in the port of London, and in which the cases of the malady were either so numerous or so flagrant as to demand the notice of the Government.

Three years ago the Medical Officer of the Privy Council had called attention to the discreditable fact that this most easily preventible disease was still extensively prevalent in merchant ships, and at his request Dr. Barnes drew up a very valuable report, founded on his experience in the *Dreadnought*, where examples of scurvy are always to be found, and in every degree of intensity.

The public is chiefly indebted to the officers of that excellent hospital for information on the subject from Dr. Budd thirty years ago to Mr. Leach, the present Resident Physician, who has been indefatigable in exposing the abuses which, as he has gleaned from the narratives of the patients, indubitably exist, and in pointing out the means of redress. A very unsatisfactory feature in the recent history of scurvy is that, notwithstanding the acknowledged improvement in the condition of our merchant seamen since 1854 (the date of the Shipping Act), the disease appears to have increased rather than diminished.

The number admitted, for example, to *Dreadnought* last quarter was 39; that for the corresponding period of the three previous years being 22, 20, and 15. The admissions annually for some years have averaged about 90; those at Liverpool about 50. But these, of course, are only the more severe cases, hundreds of others not coming under professional observation, or only casually. At the Poplar Sailors' Home, for instance, it is reported that one-half of the inmates are affected in some degree, and one-twentieth are seriously afflicted.

In the scurvy-stricken ships the proportion of sick is often very large, ranging from 9 to 90 per cent. on strength. The mean ratio of 26 ships, with crews averaging 20 in number, was four cases, or 20 per cent. Out of 55 cases received from British ships into the *Dreadnought* 14 belonged to London ships, 21 to Liverpool, and 20 to other, chiefly northern ports. Of the foreign vessels, those from Hamburgh appear to be most affected. The voyages chiefly productive of scurvy are those from India and China, the duration of which varies from 90 to 150 days. The disease seldom breaks out in less than sixty days from leaving port. Any gross defect in the diet of the crew will therefore show itself unequivocally in the last days or weeks of the homeward voyage. It is at the time of rounding the Cape of Good Hope, or soon after, that scurvy generally appears, and those whose health has been weakened previously by other causes are almost invariably its first victims. Men whose constitution is tainted with syphilis, or who have suffered from climatic disease, and have perhaps been shipped direct from an hospital in some tropical seaport, begin to complain of muscular pains and extreme lassitude. The symptoms are often so obscure as to give rise to the suspicion of malingering. Mischievous, too, is sometimes done through the excusable error of the master in treating them as cases of venereal, rheumatism, and other diseases. Instances are not rare in which even the more characteristic signs of sponginess of the gums and mouth, and ecchymosis on the extremities, have been overlooked, and the patients, as well as their

shipmates, have been in ignorance of the true nature of the disease until their arrival in England.

There is often no emaciation, nor much outward indication of illness; yet exhaustion is so great that death sometimes occurs suddenly after slight exertion, or they have to be hoisted on board the *Dreadnought* in the last degree of prostration. There recovery is generally speedy and satisfactory; yet there is reason to believe that in many cases, as pointed out by Dr. Barnes, irretrievable damage is inflicted on the constitution, and the barrier is weakened against the invasion of other diseases. Phtisis and syphilis, in particular, appear to acquire increased intensity. The latter, indeed, is as much the bane of the merchant navy as scurvy is. Both cachexies react injuriously on each other. Conjoined with intemperance, hardship, and fatigue, they shorten the lives of individuals to an incalculable degree, and, by the disgust and terror they inspire, threaten almost to extinguish a most useful class of men, and to paralyze an arm which has been, both in peace and war, of the utmost value to the country.

In all the vessels inspected the outbreak of scurvy could be directly traced to privation of vegetable food, or of its recognized substitute, good lime or lemon-juice. In a few instances the provisions were deficient in quality and quantity, but as a rule they were unexceptionable. The same may be said of the men's quarters, and other hygienic conditions of the ships. Nearly all the men examined cheerfully acknowledged that, when sick, they had been treated with humanity and attention. But in no case was a wholesome mixed dietary used, such as is enjoined by law for our emigrants, convicts, soldiers, and seamen of the Royal Navy. The lime-juice, which is an undoubted preventive, during the time of an ordinary voyage, if issued as the Act requires, was invariably found to be either of bad quality, or served out irregularly, or neglected to be taken by the men themselves. In some cases it was not the juice of limes, but a spurious compound—a solution of citric acid flavoured with oil of lemons, which is much affected by shipowners and masters as less costly and less liable to spoil than the genuine juice. Experience has amply shown that, however plausible on chemical grounds this may be, it is, like all other medicated substitutes, comparatively valueless as an anti-scorbutic. More often the lime juice, originally good, had deteriorated from being kept carelessly in a large cask, and become either unfit for use or had lost by decomposition all its prophylactic virtues. An unaccountable prejudice prevents many merchant seamen from using even good lime-juice, and its use seems in all cases to be left too much to their own discretion. Their officers rarely take it, yet seldom suffer from scurvy, although their food in the smaller ships, which seldom carry passengers, differs but little from that of the crew. Yet that slight difference is essential; a few preserves, or vegetables that will keep, and the occasional use of beer or wine, prove sufficient to insure their safety. Although the young and feeble are the first affected in scurvy ships, the disease in time spreads in some degree to all, and by the time they arrive in the cold tempestuous latitudes of the Bay of Biscay and the English Channel, the crew is often so thinned by disease as to endanger the safety of the vessel. Even when the malady has distinctly shown itself, the island of St. Helena is in many cases passed by without touching for the supplies which would at once cure it and prevent its extension. Surely this is culpable neglect. It is sometimes explained by the stringent orders of the owners prohibiting all delay. Many scorbutic invalids are left, however, at St. Helena. Mr. Leach informs us that about thirty per annum are admitted into the island hospital, whose average treatment lasts thirty-five days for each, to say nothing of the very numerous cases of out-patients, in whom the symptoms are milder.

Details were entered into of mismanagement and improvidence that led directly to the disease in the vessels inspected. In some instances the masters seemed most to blame. In most, however, the chief responsibility rests

with the owners, who practise and inculcate an ill-judged parsimony, which is attended, as we have seen, with the most pernicious results. It is well known that many ship-owners pay great attention to the health and comfort of their crews, and that scurvy among them is as obsolete and unknown as in her Majesty's ships.

In the interest of a helpless, friendless class of the community, more isolated than any other, and including thousands of foreigners, who are attracted by the high rate of wages to our mercantile marine, it would seem to be the province of the State to interfere, and by more efficient legislation to lessen the evils that now so notoriously exist. Much was done for the seamen by the Act of 1854, but as germane to this matter it is defective in some essential points—1st, in not positively enjoining a mixed scheme of diet, of which fresh vegetables, or the best preserved substitutes for them, should form a part;* 2nd, in not insisting that lime-juice, in the form of lemonade, shall be served out every day on which fresh vegetables are not actually issued; and 3rd, in not providing that the lime-juice shall be ascertained to be of good quality, and supplied in such a form as to be reliable for at least two years as an anti-scorbutic. Regulations on the 1st and 2nd heads are easy and obvious; that on the 3rd is quite as essential.

Some interesting details were given as to the varieties of lime-juice and its analysis, and samples were shown of the nauseous, worthless stuff that is found under that name in scurvy-stricken ships. Even the best lime-juice should be mixed with 10 per cent. of spirit, and packed in sealed vessels not exceeding half a gallon. It should be given even with fresh meat, if, as sometimes happens, no fresh vegetables are procurable; and in the latter part of the homeward voyage the allowance should be increased to 1oz. per diem. All the substitutes for it now in use—citric acid, salts of potass, &c., should be prohibited. For securing a good article, *ab origine*, various plans have been suggested, among others, certificates from the vendors, warranting its purity and non-liability to decomposition. Respectable dealers receiving a fair price, would not decline a responsibility of this kind, and adulteration would be checked; or the lime-juice might be supplied to ships only from bond, after having been tested there, and mixed with the proper amount of spirit. Perhaps the most efficient check would be an official inspection, not only of lime-juice, but of the other provisions, more especially the anti-scorbutics. The Board of Trade, recognizing the importance of such preventive inspection, suggested the appointment of a medical officer for the purpose at nine of the chief ports. Control in such questions is vested in the Local Marine Boards, but, with the exception of London and Hull, the proposal was emphatically negatived by those boards as "unnecessary, impracticable, and interfering injuriously with the business of the port." It is worthy of note that it is from some of those very ports that the most flagrant cases of scurvy ships proceed, and where the adulteration and counterfeiting of lime-juice is most practised.

In a vessel from Sunderland, not long ago, two deaths from scurvy occurred, and four others of the crew were long in the *Dreadnought*, suffering from the cruellest form of that disease. The lime-juice supplied to that ship was a solution of citric acid.

Other instances of the same kind were adduced from Liverpool, Glasgow, and other ports, in which the result was not fatal, but many of the crews endured great misery from scurvy in its most intense form.

Some observations were made on the medical treatment of the sufferers, particulars of which are required by law to be recorded in the official log-book. Where the disease was recognized by the captain the remedies given were judicious, but, in the absence of the necessary articles of food, were of little avail. Great allowance is to be made

* It might also include, with great advantage, an occasional ration of beer or light wine, which are anti-scorbutics of great value.

for those officers who are often placed in very trying circumstances. They have too frequently reckless and insubordinate crews to govern, and have to do their best amid difficulties which can be realized in no other situation.

It seems desirable that some knowledge of the elements of hygiene should be acquired by young officers of the mercantile marine, and that they should pass a simple examination on the subject of preserving the health of the men they are destined to command. Erroneous ideas that now prevail on dietetics and other matters would thus be corrected. With seamen well cared for and contented, discipline and right feeling could be more easily maintained. Signs of decay in the mercantile marine are said to be so evident that its present depressed condition and the causes that have led to it are likely to engage the immediate attention of Parliament.

Much of the physical suffering of seamen may, doubtless, be alleviated if their diet, which is much the same kind as it was a century ago, were improved as indicated above. Various other points of hygiene in the merchant navy were discussed at length, and allusion was made to the necessity for an extension of the recent Contagious Diseases Act to our great commercial seaports, where it is even more imperatively called for than in garisons or naval stations.

Much benefit also was anticipated to the men, the masters, and owners of the small-class ships, which, as a rule, have no medical officers, if the crew were systematically submitted to a medical examination at the time of being entered for the voyage.

EXTRUSION OF THE UTERUS WITH THE FŒTUS STILL WITHIN ITS CAVITY.

In the May number of the *Detroit Review of Medicine and Pharmacy* Dr. E. W. Jenks, Physician to Harper Hospital, relates a case of extrusion of the uterus with the fœtus still within its cavity. The woman had been in labour four days under charge of a homœopath, when Dr. J. was called in. The waters had broken about forty-eight hours before, and the attending "doctor" described the case as progressing favourably, until the head was near the vulvar opening. Digital examination had disclosed the head presenting in the first position. When, after an intermission of some time, caused by the exhausted condition of the patient, the pains returned, the head and shoulders could be distinctly felt protruding from the vagina, but surrounded by something unusual at this stage of labour. Ocular examination revealed the fact that the head and shoulders were extended from the vulva, but *still in utero!* As the os uteri was no more dilated than at first (one and a half inches in diameter) the fœtal head could be distinctly seen, while the powerful propelling force of the abdominal muscles was pushing the uterus with its contents still further "into the world," and the overstrained os was beginning to tear at its anterior edge. The child being evidently dead, and rupture of the uterus threatening, under this condition Dr. J. encircled the fœtal head with his hands, for the purpose of preventing further protrusion or laceration, while Dr. T. who had also been called, reduced the head by craniotomy and then easily delivered the trunk with the crochet, through the circle made by Dr. J.'s hands. After removal of the secundines, the uterus was replaced in its normal position. There was little hæmorrhage and no further unpleasant symptoms. Convalescence was early established and the patient recovered her former health and strength.

The history of the case previous to labour explains the hindrance to its completion. At different times during pregnancy the uterus had been prolapsed and protruded beyond the vulva. At one time in climbing over a fence she slipped and severely bruised this dependent tumour, and an abscess in the muscular tissue of the organ resulted, which discharged for several weeks and then healed. The products of reparation in the healing of this lesion were the cause of difficulty in the dilatation of the os uteri in labour; for the cicatrix, formed of firm fibrous tissue, acted as an inelastic band, limiting the expansibility of the os beyond a given extent, which in this case was insufficient to allow the passage of the child.—*Phil. Med. Reporter.*

MATER MISERICORDIÆ HOSPITAL.

CLINICAL LECTURES ON DISEASES OF THE HEART.

By Dr. HAYDEN,

PHYSICIAN TO THE HOSPITAL.

LECTURE II.

MITRAL OBSTRUCTION.

Delivered Tuesday, 26th June, 1866.

[Continued from Vol. i, page 680.]

Case 6.—Mary S., aged 26, a native of the county of Clare, admitted into hospital, May 4, 1866. Seven years ago she emigrated to the United States of America, and whilst there had several attacks of rheumatism, in one of which the heart was engaged, as may be inferred from blisters having been at that time applied to the præcordium.

She returned to Ireland in July, 1865. About a year ago her legs became swollen. The swelling disappeared after a short time, but it has since occasionally returned. A month previous to the date of admittance she threw up a quantity of blood, and again a fortnight later.

Present condition.—Pulse 72, weak, but regular; tongue clean; appetite bad; bowels free; face fresh-looking, and free from congestion; œdema of feet; chest universally resonant, and respiration natural; dyspnœa on exertion; area of præcordial dulness not increased; apex beat feeble, and in normal situation; here both sounds are distinct, the first a shade softer and more prolonged than natural, but unattended with murmur. *Immediately preceding* and extending to the first sound is a soft bellows murmur, occupying the latter portion of the diastolic pause, and perfectly distinct from either normal sound. This murmur is loudest at the apex; it is faintly audible at the base; not at all in the course of the aorta, but distinctly audible at the inferior angle of the left scapula. The second sound is greatly intensified over upper edge of left third costal cartilage, in the area of the pulmonary artery. To have chlor. ether and aromat. spirit of ammonia, of each ℥iij., in camphor mixture to eight ounces; a tablespoonful to be taken three times daily; nutritious diet, fresh air, and very gentle exercise.

May 15th: A murmur accompanies first sound to-day; no murmur precedes it.

May 16th: Condition is much improved; no œdema of feet; pulse now strong, as well as regular; appetite and sleep satisfactory; no systolic murmur audible to-day; præ systolic murmur distinct as on the day of admission. Patient discharged at her own request, as she declares she feels well enough to resume her duties as house-servant.

This was by no means an aggravated case of mitral contraction; or rather the disease was, in this instance, in its earliest stage, after the subsidence of the acute inflammation which gave rise to it. The symptoms and signs were, however, quite unmistakable; thus, the rather fresh tint of the face, associated with a quick and thready (though in this instance, not irregular) pulse; œdema of the feet; slight dyspnœa on exertion; expectoration of blood, with scarcely any cough, and none of the signs or symptoms of phthisis; and above all, the characteristic murmur preceding the first sound of the heart, and loudest at the apex, left no doubt whatever upon my mind as to the precise nature of the cardiac lesion to which they were due.

Since I commenced to prepare this lecture another case (being the seventh) of mitral contraction has come under our notice; it is now in St. Catharine's ward, and you have an opportunity of studying and applying to it the diagnostic rules which I have laid down for your guidance.

Case 7.—Jane M., a poor woman, remarkably thin, aged 50, was admitted June 1, 1866; health has been moderately good; has never had rheumatism; two years

ago, after suffering much mental distress, she experienced, for the first time, palpitation and pain in the region of the heart; latterly her feet and legs became swollen; pulse so weak and irregular that it cannot be counted at the wrist; it is quite imperceptible on the right side, and barely perceptible on the left; counted by the heart it registers 150 in the minute; liver is much enlarged in both lobes, and descends nearly to the umbilicus; it is prominent but even on the surface, and not tender on pressure; there is not, nor has there been, jaundice; slight œdema at outer ankles; fingers and toes cold and livid; face rather fresh in colour, and not indicative of cardiac distress; heart's action remarkably irregular; both sounds clear and ringing, unattended with murmur, and extensively transmitted over front of chest; especially loud in course of aorta; cardiac impulse strong and labouring, contrasting markedly with radial pulse; apex-beat diffused, but not towards left side; resonant and respiratory sound over lungs are normal; some mucous râles over base of right lung. To have a rhubarb draught and two ounces of whisky with nourishment.

June 2nd: Pulse barely perceptible on right side; somewhat stronger on left, and 84 in the minute. Patient feels better. To have a tablespoonful of the following three times daily:—R. Tinct. ferri sesquichlorid. ether. chloric. aa. ℥ii., infusi quassia ℥viiss. M.

June 10th: Much œdema of feet and legs; orthopnœa; dulness over base of left lung, and here coarse crepitant râles are heard. To be dry-cupped over lower part of left side of chest, and take the following, viz.:—Tinctura digitalis gtt. v., spirit. juniper. c. ℥i. in mist. camphoræ ℥i. every sixth hour.

June 12th: Passed a bad night, having slept scarcely at all. To have chloric ether ℥i., solution of muriate of morphia ℥ii., in an ounce of camphor mixture every night.

15th: Pulse not perceptible on right, and barely perceptible on left side; it is irregular and intermittent, as is likewise heart's action. A *systolic* "whiffing" murmur is audible over the apex, or rather somewhat to the left of the nipple to-day; it is not audible elsewhere; both cardiac sounds are heard at the inferior angle of the left scapula, but no murmur. Second sound is much intensified over root of pulmonary artery; dulness on percussion over base of left lung, where respiration is feeble and attended with crepitus; spat some blood mixed with mucus last night; œdema of lower limbs; face free from œdema and lividity; no venous engorgement of neck; very little respiratory distress, save at night; a stinging pain occasionally experienced in region of heart; this has been relieved by an opiate plaster.

June 19th: Pulse 108 counted by the heart; orthopnœa; scarcely any respiratory distress in sitting posture; both sides of chest dull inferiorly, and to a corresponding extent respiration is weak and accompanied with obscure crepitus; has continued to expectorate a little blood since last report; an obscure rubbing or grating murmur immediately preceding the first sound is heard over the apex; it occupies the latter portion of the long or diastolic pause, but does not touch the first sound. For the last few days, having a strong impression on my mind that this case was one of mitral constriction, owing to the peculiar grouping of signs and symptoms so closely resembling those of the cases already detailed, I had been looking out for the characteristic præ systolic apex murmur, and mentioned my suspicions to the class. To-day, for the first time, this murmur was distinctly heard and identified, and thus the evidence of mitral obstruction was rendered complete.

June 21st: Pulse 114; respirations 30; urine 1015 s.g., acid, and free from albumen; murmur is to-day systolic exclusively.

June 22nd: Præ systolic murmur alone audible to-day; it is rough but faint, and audible only occasionally—i.e., when, as happens once every two or three minutes, the heart acts several times with unusual force and rapidity.

June 23rd: Præ systolic murmur remarkably distinct to-day, and is the only murmur present; it is not audible in

back, nor is second sound accentuated over pulmonary artery.

Before attempting to estimate the diagnostic value of the *præsystolic* apex murmur, as evidence of obstruction at the left auriculo-ventricular orifice, it is necessary you should have a definite and correct idea of the natural order, grouping, and rhythm of the phenomena which constitute a cycle of the heart's action.

As I cannot make this portion of our subject clearer than by quoting from my paper on "The Rhythm of the Heart's Action," read before the Medical Society of the College of Physicians on the 19th May, 1865, I will take the liberty of doing so briefly:—

"The whole period covered by a single action of the heart is divisible into two parts of unequal length, corresponding to the *ventricular systole* and the *ventricular diastole*. Of this period one-third is occupied by the ventricular systole, and two-thirds by the ventricular diastole, the pulse being at the rate of 90 in the minute.

"The first sound and the impulse initiate the ventricular systole, and are immediately succeeded by a short period of silence, or a pause, during which the ventricular systole is continued; this pause, which corresponds to the 'short pause' of French writers, I propose to distinguish by the title of 'systolic pause,' as indicating the state of the ventricles during its occurrence; it is of very brief duration, at the normal rate of the heart's action, not calculable, but distinctly appreciable by the ear, and is a pause only in the sense that that portion of the ventricular systole which coincides with it is unattended with sound.

"The second sound immediately succeeds the systolic pause, and determines its duration; the period of time covered by it is quite incalculable, but belongs to that assigned to the ventricular diastole. It is succeeded by a long pause, which I propose to designate as the 'diastolic pause,' in contradistinction to the former.

"This pause corresponds to the interval between the second sound and the first, and, at a pulse-rate of 90, occupies a period of one half second, *minus* the length of the second sound. During this pause the ventricles are undergoing dilation and the auricles contraction. There is, therefore, no pause in the sense of complete absence of movement of any of the chambers of the heart; the so-called pause is a period of *silence*, not one of inaction.

"During the period corresponding to the second sound and the diastolic pause—that is, to the ventricular diastole—the auricles are in a state of contraction; this is feeble and of an undulatory character till towards its conclusion, when it becomes quick and energetic, completing the distention of the ventricles, and is immediately succeeded by their contraction. This terminal portion or acme of the contraction of the auricles I propose to designate the 'momentum of the auricular systole,' because then the auricles, having discharged a portion of their contents, have acquired their maximum power of contraction, and propel a further volume of blood with increased force and rapidly into the ventricles.

"The forced and sudden entrance of blood into the ventricles during the momentum of the auricular systole serves the useful purpose of communicating to the ventricles the stimulus of distention, in response to which they immediately react upon their contents, and thus complete the cycle of the heart's action."

A murmur occurring during the period of the first sound is usually designated a "systolic murmur," and a murmur occurring during the period of the second sound a "diastolic murmur"—that is, *ventricular systolic* and *diastolic* respectively. This nomenclature would be unobjectionable did the ventricular systole accurately correspond in duration with the first sound, and the ventricular diastole with the second sound. Such, however, is not the case; for the ventricular systole, as already shown, extends over the first sound *plus* the systolic pause, and the ventricular diastole over the second sound *plus* the dias-

tolic pause. Hence, it should be distinctly understood that the terms "systolic" and "diastolic," as now commonly applied to cardiac murmurs, are intended to convey that the murmurs spoken of *coincide with, or replace,* the normal first and second sounds respectively. With this limitation the terms are quite unobjectionable, and may be allowed to stand; but without it they must lead to confusion and laxity in diagnosis.

The application of the terms "systolic" and "diastolic" being thus restricted to what they are really meant to express—namely, murmurs coinciding with the sounds of the heart—it is manifest that other designations must be found for murmurs which are *out of time* with these sounds. To this class of murmurs belongs, in a præminent degree that which has been named "præsystolic," and by Gairdner "left auricular systolic;" the former term implying that the murmur *precedes* the first sound which inaugurates the ventricular systole, and the latter, that it coincides in time with the contraction of the left auricle.

If the limited application of the term "systolic," already suggested, be borne in mind, the designation "præsystolic," as applied to this murmur, will be strictly appropriate, sufficiently expressive of its rhythm, and the most convenient for use.

The pitch and quality of this, as of other cardiac murmurs, will be found to vary in different cases. It is, however, usually harsh and whispering; thus, rrrr fine, in time it occupies the terminal portion of the long or diastolic pause; immediately *precedes* the first sound, running up to, without extending into it, and therefore coincides with the acme or "momentum" of the auricular systole.

A murmur of this character and rhythm, loudest at the left apex, not audible, or faintly so, at the base, and not transmitted save occasionally to the left side of the lower dorsal spine, may be regarded as diagnostic of mitral obstruction; and if, to the physical evidence thus afforded, be added œdema, rarely and never till the last stage of the disease, extending to the face; comparatively trivial venous engorgement, shallow respiration, dyspnoea, and occasional hæmoptysis, not due to primary disease of the lungs; and lastly, the thread-like, faltering, irregular, and intermitting pulse, the evidence is now complete, and fully warrants the confident diagnosis of narrowing or stenosis of the mitral orifice.

Taken alone, and with the limitations as to site and rhythm already mentioned, the murmur now described may be considered pathognomonic, but without these qualifications a localized atrition murmur due to pericarditis, and possibly also a murmur caused by patency of the foramen ovale, or by an aneurism of the left auricle, may be mistaken for it.

None of these murmurs, however, would have its point of maximum intensity at the left apex, or be inaudible at the base. Nor, in the absence of mitral constriction, would any of them be associated with the remarkable group of symptoms already described as characteristic of this lesion.

It is right I should inform you that stethoscopists are by no means agreed as to the identification and significance of the præsystolic murmur; some deny it altogether, and many, whilst admitting, attribute it to causes other than mitral obstruction.

It is no part of my duty to reconcile or explain these discrepancies; I am content to reassert in the most confident manner all I have advanced in relation to this murmur, and to express my conviction, notwithstanding the scepticism or dissent of men for whose opinions I have the greatest respect, that ere many years it will have assigned to it a prominent place in the catalogue of acoustic signs which yield definite and positive evidence of special structural lesions of the heart.

Dr. Blakiston ("Diseases of the Heart," 1865, page 246) says, "The chief physical sign of mitral obstruction is a diastolic murmur; it is rarely, however, that such a murmur is engendered, because the size of the auriculo-ventricular opening is so large," &c. Here the murmur

of mitral obstruction is described as "diastolic;" this is not strictly correct in the conventional sense, and by fixing attention exclusively on the second sound may lead either to non-observance of the murmur where it exists, or to non-identification of its true nature even when detected.

Præsystolic murmur is, no doubt, frequently absent in cases of veritable mitral obstruction, but never till the advanced stages of the disease, when the vigour of the heart has become much impaired, and even then *only at intervals*, except as regards the period immediately preceding dissolution.

Dr. Peacock ("Valvular Diseases of the Heart," 1865, page 109) says, "In cases of mitral disease it would often be difficult, if not impossible, to distinguish between simple obstruction and regurgitation;" and Dr. Andrews, in his recent article "On the Diagnosis of Systolic Endocardial Murmurs whose point of greatest Intensity is at or near the left Apex of the Heart," published in the first volume of "The St. Bartholomew's Hospital Reports," October, 1865, writes, "At the same time it must be confessed that the diagnosis of a præ systolic from a systolic ventricular murmur is one of the most difficult tasks in the physical examination of the heart, and is often all but impossible."

I have thus collated the opinions of three of the most recent writers on diseases of the heart, in order that you may understand the present state of knowledge on this subject and have your senses sharpened for further observation.

Skoda says (Markham's translation, page 232), "In the left ventricle during its diastole a sound unaccompanied by a murmur—second sound—indicates that there is no constriction of the left auriculo-ventricular opening, and that the blood, in passing from the left auricle into the left ventricle, does not flow over any roughened surface."

In reference to this passage I will only observe that the diastole of the ventricles commences *with* the second sound, and ends *at* the first; that the only sound occurring within this period is the second, which is never *accompanied* by murmur in simple obstruction at the mitral orifice, whether constrictive or not; and that, therefore, the absence of murmur with the second sound affords no evidence whatever of the absence of disease at the left auriculo-ventricular opening. The murmur indicative of mitral constriction or roughening occurs in the latter portion of the long or diastolic pause, in the "præsystole" of Gendrin, and is therefore preceded and separated from the second sound by the first and greater portion of that pause.

To Dr. W. T. Gairdner of Glasgow is due the chief merit of having established, in a clear and satisfactory manner, the differential diagnosis of mitral obstruction, and of having brought it prominently before the profession.

In his original and admirable work, "Clinical Medicine," 1862, page 599, Dr. Gairdner says, "Auricular systolic murmurs are certainly not rare; for here are seven of them, at least, in three months, as a counterpart to the same number of aortic murmurs, which nobody will assert to be rare. To me they are among the commonest and the most easily detected of all the cardiac murmurs; and, seeing that I regard the auricular-systolic murmur as all-important in the diagnosis of primary mitral disease, you may trust me when I tell you that in many years' hospital experience I have not seen a single instance in which an auricular-systolic murmur, being of mitral origin, has been produced by mere regurgitation, not a single instance in which such a murmur has occurred without either vegetations or contraction of the orifice. On the other hand, I have seen many cases of widely-dilated mitral orifice with evident regurgitation, but without obstruction or deformity; and in every one of these cases the murmur (if present at all) has been ventricular systolic. In our seven cases, therefore, I feel as sure as I can well be of anything in medicine that we have to do not only with mitral disease, but with mitral obstruction." I willingly and cordially subscribe every word of this passage, with one re-

servation—I do not think the præ systolic murmur easy of detection; it requires close attention, and a readiness in seeing and appreciating the peculiar and distinctive *rhythm* of the murmur, and therefore considerable practice, to detect it in the majority of cases.

Dr. Gairdner's cases were seven in number, as published in the "Clinical Medicine," amongst which were two deaths and one dissection, the latter confirmatory of the diagnosis.

My cases are also seven in number, with three deaths and three dissections; in six out of the seven the diagnosis was made; in the seventh it was not made for reasons already given, although post-mortem evidence showed that mitral constriction was considerable. In the two remaining cases in which a post-mortem examination was made it was confirmatory of the diagnosis.

The prognosis in these cases is of the most unfavourable character. I cannot altogether agree with Dr. Gairdner in the opinion that "mitral regurgitation on the average of cases is a much more immediately dangerous form of disease than mitral obstruction;" it may be more "immediately," but is not more certainly fatal than mitral obstruction.

In regard to treatment, very little need be said. The tendency to death is by asthenia and vascular engorgement of the lungs; the former due to failure of the systemic circulation by defect of supply, and the latter to obstruction on the left side of the heart. The object of treatment should therefore be to sustain the failing circulation by increasing the contractile force of the heart, which probably has itself suffered some impairment by defective coronary circulation.

This is best accomplished by the administration of ethereal and alcoholic stimulants, and by nutritious diet frequently given, and in a concentrated form.

Congestion of the lungs should, at the same time, be kept in check by means of dry cupping and counter-irritation, and the *volume* of the blood kept at a low standard by mild hydragogue aperients and diuretics. I have found much benefit in the treatment of these cases from the use of tincture of the sesquichloride of iron and chloric ether, of each three drachms, in seven ounces of infusion of quassia; a tablespoonful to be taken three times daily.

I have now done, and for the length to which my observations have been extended, the interesting nature of the subject, its novelty amongst us, and my desire to put you in possession of the clinical history and distinctive characteristics of these cases, and of the present state of knowledge on the subject generally, must be my apology. I shall continue to use such opportunities as may be presented to me of making further observations on this subject, and at some further time I hope to lay the result before you.

CEREBRO-SPINAL ARACHNITIS.

By P. C. LITTLE, F.R.C.S.I., &c.

Case 1.—At 9 p.m., of the 28th February, having visited M. M., aged 38, the mother of twelve children, and in her seventh month of pregnancy, I found her insensible and in fearful convulsions, which continued for about five minutes, after which there was an interval of comparative ease. During this period the patient's body was rigid, and appeared to rest upon the vertex and heels. The face was dark and puffy; jaws open and foaming; tongue protruding, lacerated, and too large for the mouth; eyes staring; pupils dilated; conjunctivæ suffused; muscles, especially of upper extremities, quivering; hands clenched; skin very dry and hot; pulse 120, sharp, but small; respirations difficult, irregular, mean 22; heart's action quick but otherwise normal; lungs healthy; bowels free; stomach sick; deglutition almost impossible; convulsions recurring every quarter of an hour.

I could detect nothing in the condition of the uterus to account for those alarming symptoms; but I perceived

a determination of blood, and an increase of heat along the spine, and with digital pressure discovered deep-seated tenderness extending on either side of it, from the fourth cervical to the third dorsal vertebra.

There was nothing in the history of the patient's family to explain this illness; and she herself had enjoyed excellent health up to two years ago, the date of her last confinement, in which she caught cold, and since which she has been delicate; has frequently had pains in the back, and slight attacks of convulsions about every second month, without loss of sensibility. The present visitation came on suddenly, and has continued for more than twenty-four hours, with unconsciousness, and is increasing in severity, although she has been actively treated with enemata, aperients, sinapisms, stupes of turpentine to the abdomen, and fly blisters behind the ears.

I advised the immediate application of twelve leeches to the spine, to be followed by hot poultices of bran and linseed meal; a powder of calomel and jalap (twenty grains of each) to be at once administered, and warm drinks of whey or barley-water when admissible.

On my visit next day, I was informed that the dangerous symptoms disappeared, and that consciousness returned during the leeching. There had been, however, some muscular spasms since that. The patient being now able to converse with me, complains of pains all over, of soreness of tongue, and of flashes of fire before her eyes. Her face is more tranquil; pupils still dilated; pulse 100, soft; skin much cooler.

I then placed her upon a short course of mercury, with James's powder (gr. ij. of the former, and gr. iij. of the latter, every third hour), and ordered a lotion for the tongue. In a short time the disease yielded to this treatment, which I terminated with blisters to the spine and general tonics. On the 13th March she was quite well, and took a drive in the country. I afterwards heard that at her full time she brought forth a living child, and that there had been no return of the convulsions.

Case 2.—R. S., aged 13, a plethoric muscular girl, suffering from convulsions with cerebral disturbance, was placed under my care January 18. The attacks recurred about every half-hour, and lasted for nearly ten minutes, during which time the body was strongly curved backwards; the muscles, and in particular those of the arms and face, were awfully convulsed; respirations rapid and irregular; countenance purple and swollen; mouth frothing; jaws firmly set, with some teeth broken from grinding; eyes rolling and winking; pupils dilated; conjunctivæ injected; insensibility, and frequent screaming. The fit subsided with the apparent exhaustion of the patient. In the intervals, the opisthotonos and tonic spasms continued, and consciousness partially returned. She complained of pains in the head and back, and of sickness of stomach. The menses had not yet appeared.

On examination, I observed photophobia, nervous irritability; calor mordax of skin; cold feet; pulse 140, variable in volume; physical developments, indicative of the approach of the catamenia; signs of local inflammation along the spine, from fifth cervical to sixth dorsal vertebra, with great tenderness over the third dorsal.

The disease seems to have originated in cold in the following way:—A fortnight ago, during the frost, the patient imprudently went into the garden in her bare feet, to play on the ice, of which she ate freely, and after having spent some hours in that way, felt a great chill, became very sick, and went to bed. Restoratives were given, and heat applied to relieve the shivering, but she grew worse; soon pains all over, headache, sickness of stomach, twitching of the muscles, and feverish symptoms set in. The day following slight convulsions occurred; ever since which they have been increasing in frequency, severity, and duration, notwithstanding that many remedies had been tried to allay them.

I ordered eighteen leeches at once to the tender part of the spine, and afterwards hot poultices; and an aperient immediately of cal. gr. x., and pulv. jal. co. gr. xv.

Next day she was better; slept pretty well last night; spoke sensibly; convulsions much less frequent and lighter; pulse 128, fuller and softer; face flushed; pupils dilated. I then put her on calomel and James's powder, until the system became affected, when I blistered the spine repeatedly, and pursued general tonic treatment. By such means the patient was perfectly restored in less than a month.

The following is a summary of the grounds of the diagnosis in these cases:—

1. The strong incurvation backwards of the spine.
2. Tetanic character of the convulsions.
3. Tonic spasm of the muscles.
4. Spinal tenderness.
5. Cerebral disturbance.
6. Irregularity of respiration.
7. History of the cases.

The foregoing left little doubt as to the nature of the disease. It had many features in common with affections of the spinal cord or its coverings, while it differed from those in some important particulars. Thus, in tetanus, cholera, or strychnia poisoning, we observe opisthotonos, convulsions, spastic contraction of the muscles, and irregularity of respiration, such as existed in these cases, but not the spinal tenderness and unconsciousness which distinguished them. On the contrary, the diseases mentioned are remarkable for exalted sensibility and acuteness of intellect. Strong cerebral derangement, when associated with such spinal indications as were in the present examples, may therefore be looked upon as of much value in the diagnosis of cerebro-spinal meningitis. And' if we adopt the opinion of Martinet and others, the measure of such derangement will depend upon the extent to which the meninges of the brain (probably those of the anterior superior aspect) may be implicated.

M. Trousseau, and the late lamented Dr. Mayne, who added much to our limited knowledge of this obscure subject, attached great importance to the character of the respirations in this disease. In the present cases, inspiration was strong and forced relatively to expiration, which was feeble, and generally almost inaudible. The respirations were rapid and irregular during a convulsion; afterwards they became slow and intermitting, and at times appeared as if they had for ever ceased.

The history of each case assisted materially in the diagnosis, as it pointed to cold as the exciting cause of the disease. What were the pathological effects which this agent may have produced in the envelopes of the spinal cord and brain?

If we accept as axioms in the human economy that the more complex the organism the more easily its harmony of parts and functions may be disturbed, and that the vascular supply is in proportion to the activity of the organ, we may arrive at a solution of the question. Without doubt the cerebro-spinal apparatus is the most wonderfully complicated, the most active and vascular portion of the system, and therefore most susceptible of derangement from disturbing causes, such as cold, external injury, tubercular deposits, &c. Moreover, if such influences act under circumstances in which the nervous system may be long and intensely excited, evil consequences are more certain to follow, illustrations of which we have before us. Thus, in Case 1, the many previous labours of the patient, her impaired health, and the extreme excitement of her cerebro-spinal and sympathetic systems during parturition, favoured the action of the exciting cause, which began by retarding the functions of the capillaries, induced a low form of inflammation, and ended in the symptoms described.

In the 2nd Case, the same cause operated upon a system preparing to undergo the most remarkable change in female life, and one always preceded by great nervous and vascular excitement.

That the disease commenced in the capillaries we

may reasonably infer from the delicacy of their mechanism, their known susceptibility for cold, and the slight occasions which may disturb their nervous relations. Pathology adds still stronger proofs in favour of this view. In cases such as these, during life the local effects of inflammation are noticed, at least as regards the spine; and after death, the more advanced products of inflammatory action are seen in the thickening of the membranes, adventitious deposits, effusions, and increased vascularity. The last condition is most general and most distinct where the capillaries attain their highest development in the pia mater of the cord and brain.

Presuming that this disease originates from the action of a foreign element, subverting the dominion of the sympathetic nerves over the capillaries, it may be asked why these nerves in preference to the cerebro-spinal are assailed? It may be because, the latter appointed for more active offices, are endowed with higher vitality, and are less exposed to disturbing causes than the former. The sympathetic system appears to hold a secondary place in man's organization, in controlling the vast cerebro-spinal current, which is destined to sustain, but which, without restraint, may extinguish, animal life. These two great nervous forces resemble in a manner the opposite poles of a magnetic battery. They act and counteract upon each other, the cerebro-spinal generally preserving a positive and preponderating influence. In some epidemics the latter is the more remarkable, as (on our hypothesis) its counterpoise, the sympathetic power, is suspended.

This disease occasionally assumes an epidemic character assignable to some local depressing cause. It so occurred in this country in the lamentable famine of 1846; in France, when large bodies of conscripts were crowded together; and in the United States, during sudden and great changes of temperature.

The cases before us had many epidemic features. They happened about the same time; in the same locality, a badly drained one; they had a common origin—cold; and were amenable to the same remedies.

The treatment was modified according to the circumstances of each case. Had I seen the patients before the disease had fully established itself, I should have tested the advantages of ice to the spine, so much extolled in kindred affections. There seems to be no reason why the early use of such an application, combined with antimonial saline aperients, should not relieve the spinal congestion, and restore tone to the capillaries. However, the period in which that might have been of service having passed by, I felt called upon to subdue the high inflammatory action that ensued. Blood was therefore quickly extracted from the tender part of the spine, with a two-fold object—firstly, to afford speedy relief to the patient; secondly, to gain time for the action of a more certain and permanent remedy. In meningitis, save perhaps in the tubercular form, timely local blood-letting will be of great benefit. Here the most gratifying effects followed this treatment, which was directed against the most evident seat of the inflammation. In similar cases, but without spinal tenderness, we might, with like fortunate results, begin by treating the most prominent symptoms, whether they be referable to the spine or the cerebrum; and afterwards we may act generally upon the disease, and so complete the cure. To attain this end, we rely solely upon mercury. In the last century, Dobson recommended it in acute hydrocephalus, on account of its action upon the absorbents. There can be no question regarding its efficacy in cases like the present, whatever objection there may be to its use in tubercular meningitis. In the latter, perhaps counter-irritation by blisters, setons, or escharotics, with general tonic treatment, would be most successful.

THE DUKE OF EDINBURGH laid the foundation stone of a new infirmary for children, at Liverpool, on Saturday.

Hospital Reports.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

CASES UNDER THE CARE OF MR. PORTER,

SENIOR SURGEON TO THE HOSPITAL.

[Reported by ARTHUR WYNNE FOOT, M.D.]

(Continued from Vol. i., page 682.)

EPITHELIOMA IN THE LOWER LIP OF A FEMALE.

Case 24.—A woman, 77 years of age, was admitted early in the present month, under Mr. Porter, with an epithelial ulcer at the left side of the lower lip. The ulcer was oval, involving the free border of the lip and equal portions of its mucous and cutaneous surfaces. She had been a smoker for the last forty years; the present ulcer originated about twenty years ago in a crack or fissure, which healed up and reappeared from time to time, until by degrees a distinct sore became established. Since the year 1861 twenty cases of epithelial cancer have been operated upon in the Meath Hospital, and of these but two were females. In connexion with this circumstance Mr. Porter remarked upon the predilection of this disease for the lower lip. The preference of this disease to attack the male sex and lower lip is observed in all countries. Of eighty-one patients affected with labial cancer in the practice of Riberi of Turin, three of the cases occurred in women, and in only four was the upper lip affected. He also alluded to the advanced age at which this disease generally appears, and to the frequency with which this form of cancer appears to be connected with external rather than internal agencies. Though the disease is very frequently assigned to the irritation of a pipe, so much so, that the late M. Roux attributed the fact of his having met with a larger proportion of cancerous affections of the lips during the latter half of his surgical career to the increase in the practice of smoking, yet others have met with many cases of the disease in such places as among the peasantry of the mountains of Puy-de-Dome, and the vicinity where smoking is almost wholly unpractised. The prevalence of this disease among the lower classes, which all have observed, is attributed by Riberi chiefly to local irritation of the lip from any cause, neglect of personal cleanliness, and exposure to the vicissitudes of the weather. From a statistical analysis of one hundred and twenty-seven cases of epithelial cancer, published in the *Medical Times and Gazette* of 1860, it is shown that women are the subjects of this disease in the proportion only of 5 to every 100 males; that when it does occur in women it is usually in those who have been accustomed to smoke; that the lower lip is affected in 90 per cent. of the cases, the angle of the mouth in 6 per cent., the upper lip in 4 per cent.; and that the average age of patients suffering from cancer of the lip is 58 years.

RODENT ULCER AT THE INNER SIDE OF THE EYEBROW— TREATMENT WITH SIMPSON'S PASTE.

Case 25.—A shoemaker, 45 years of age, came under Mr. Porter's care, as an out patient, early in the present month with an ulcer situated close to the inner side of the left eyebrow, almost immediately above the articulation between the frontal and nasal bones. It was of irregular outline, the edges hard and raised, the surface much depressed, dry, and clean, without discharge or fetor from it. Till recently it caused no pain, although it had existed for six years, having originated from the wound received by hitting his head against a door. This wound never healed, but slowly increased in size; no exfoliation of bone occurred, nor was there any evidence of dead bone lying in the ulcer. There was no enlargement of the cervical glands, nor any deterioration of his general health. His anxiety to get cured arose chiefly from the unsightly ap-

pearance of the sore, and because its vicinity of the inner edges of the eyelids caused them to swell and interfere with the use of that eye in the pursuit of his trade. Mr. Porter filled up the excavation of the ulcer with the escharotic paste of Sir James Simpson, made by mixing intimately finely-powdered anhydrous sulphate of zinc with glycerine, in the proportion of a drachm of glycerine to one ounce of the powdered zinc. The pain of this caustic commenced in about half an hour after its application, and continued severe, but not unbearable, for four hours. Mr. Porter observed, in reference to the use of this caustic in rodent and epithelial ulcers, upon the advantages it possesses in not being deliquescent, and therefore very manageable, in its action being limited to ulcerated or abraded parts, the surrounding skin remaining uninjured, and upon the slight local inflammation it excites. It, moreover, acts rapidly, and will keep for any length of time. The effect of this caustic is the separation of a slough of a white colour on about the fifth day, leaving a granulating wound disposed to cicatrise.

That this ulcer deserved the name of the rodent ulcer, given to it by Lebert, and adopted in this country by Paget, was apparent from its neither belonging to a lupous nor epithelial variety of sore. In a clinical report published on this subject by Mr. Jonathan Hutchinson, it is stated that this ulcer differs from lupus exedens in that it never occurs in the young, and never gets well spontaneously, while lupus exedens but rarely begins after the age of thirty, and usually tends, after the lapse of time, to cicatrise spontaneously. The ulcer in question differs from cancer in that there is but seldom present any tendency to the production of new material, that it never causes the glands to enlarge, nor induces morbid growths in the internal viscera. It is most commonly met with between the ages of 50 and 60, and is equally frequent in both sexes. The diagnosis is thus set forth. An ulcer, with a hard sinuous edge, situated on some part of the skin of the upper two-thirds of the face, of several, perhaps many, years' duration, almost painless, and occurring in a middle-aged or elderly person, of fair health, and without enlarged glands. Mr. Hutchinson pays a well-deserved tribute of praise to the accuracy with which Dr. Jacob, prior to all others, described this disease, in the fourth volume of the "Dublin Hospital Reports," under the title of "Observations respecting an Ulcer of peculiar Character, which attacks the Eyelids and other parts of the Face."

BITE IN THE LEG FROM A DOG—APPLICATION OF STRONG NITRIC ACID IMMEDIATELY AFTERWARDS.

Case 26.—On the 8th of June, a boy, 10 years of age, applied at the hospital, having been bitten in the calf of the left leg, about five minutes previously, by a large and angry, but not rabid, dog. The wound was on the outer side of the leg, the inner side being merely marked by the teeth. It bled but slightly, but the boy suffered much pain, and was greatly frightened. Mr. Porter washed the wound, and applied strong nitric acid with a piece of pointed stick to every part of it, following the track of the teeth in all directions. The wound was then covered with a linseed-meal poultice, and a draught containing tincture of hyoscyamus in camphor mixture was administered. The slough resulting from the action of the nitric acid separated on the ninth day, and the wound is now almost healed by granulation, the local application being lotion of chloride of lime. With reference to the likelihood of serious consequences from the bite, Mr. Porter observed upon the advantage the boy had derived from having had a pair of trowsers on him at the time, which probably served to wipe the saliva off the teeth, and upon the advantages of employing a fluid caustic, which, by penetrating to every part of the wound, is much more certainly brought into contact with any virus than solid or powdered escharotics can be. He alluded to the lunar caustic, as highly recommended by Mr. Youatt, who has employed it on upwards of four hundred persons, and

four times on himself, after bites from dogs decidedly rabid, and in none of these cases did the disease appear in the bitten persons so treated. It has been questioned whether the bite of dogs, not rabid, but simply infuriated, can cause the so-called hydrophobia in the human subject; but cases have certainly occurred of the death of the persons bitten, the animal not having, up to that time, exhibited any symptoms of rabies. It is satisfactory that persons bitten by animals known to be rabid, only about one in four become subsequently affected with madness, or even a still less proportion, as Hunter gives an instance in which, out of twenty persons bitten by the same dog, only one received the disease. The poison of rabies is much more communicable to the lower animals than to man.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

ARACHNITIS AT THE BASE OF THE BRAIN CHIEFLY.

Case 1.—P. M., aged 17, was admitted into the Hardwicke Hospital, labouring under simple fever, from which he convalesced in about three weeks. A brief relapse of the febrile state, with very ill-defined symptoms, took place after an interval of about ten days, and from this attack he recovered in about seven or eight days, and was about to be discharged when he again fell ill, and now presented symptoms of a totally new character. He complained of intense headache, with constant vomiting of a greenish-yellow fluid. The tongue was furred, the skin moderately hot, and the pulse under 50 for several days. His head was shaved, leeches applied in repeated relays to the temples, and cold lotions placed upon the scalp. After the bowels were well cleared, small and frequent doses of calomel were administered, and mercurial ointment rubbed into the axillæ. Subsequently the head was freely blistered. Gastric irritation with the greenish bilious vomiting above referred to continued to the third day, and then subsided not to return again. The headache, however, continued with little or no intermission or alleviation, and the patient constantly moaned and complained of his head day and night, and was utterly exhausted from want of rest. He occasionally partook of food, which was now retained on the stomach, and at a later period readily took wine. The urine was surcharged with phosphates. Rapid emaciation was observable, and obstinate resistance to the specific action of mercury was remarked and commented on by Dr. Lyons in this and the following case, as well as in some other instances of lesion of the nerve-centres occurring about the same period.

When the conditions just noted had lasted for some three or four days, dilatation of the pupils became observable. The shape of the pupil was singular; it was that of a perfect ellipse, the major axis of which was directed from above downwards, and was about double that of the minor. This condition was uniform in both eyes, and was unattended at any time by strabismus or the slightest defect of vision. Consciousness was retained till the day before death.

On post-mortem examination, beyond some venous turgescence and inconsiderable serous effusion, but slight evidence of general arachnitis was detected until the base of the brain was examined. The arachnoid in the circle of Willis was thickened and opaque from yellowish gelatiniform effusion. On opening the ventricles there was an escape of serum, but not in excessive quantity.

Case 2.—A sailor, aged 18, a native of Scotland, was admitted into the Hardwicke Hospital on June 15. He was of well-developed frame, laboured under congenital convergent strabismus of the right eye, and was stated by his father to have been always a healthy lad, though somewhat dull and laconic in speech. Six months before admission he had been confined to bed for a week with a

rheumatic affection, the exact pathological nature of which was not discoverable. On the 30th of May he shipped for Howth on a fishing expedition, had a three days' voyage, was slightly sea-sick, and was rather confined in his bowels. Soon after reaching Ireland his appetite failed, constant vomiting set in, and he suffered from severe and continuous headache. Obstinate constipation was present, and besides salts and castor-oil, light enemata were administered prior to his reception into hospital. On admission he was found very dull, heavy, and stupid; he complained much of the severe pain in his head, and frequently vomited a greenish-yellow fluid. There was also observable a certain amount of rigidity of the muscles on the posterior right side of the neck, and any attempt to nod the head forward was attended with much pain. He was perfectly conscious, though uncommunicative, and it was exceedingly difficult to get from himself any account of his history or symptoms. The pulse was found to be but 72, and it never went beyond 84 until the day preceding his death, when it suddenly ran up to 140.

The head was shaved (with much difficulty, owing to numerous thick patches of porrigo); leeches were applied to the temples, a blister to the nape of the neck, and subsequently the head was freely coated with acetum lyttæ, and copious vesication maintained. Calomel was administered, mercurial ointment rubbed into the axillæ and applied to the blistered surface, and enemata were repeatedly given.

On the 21st, six days after admission, and then, for the first time, dilatation of the pupils was noticed, that of the right eye was irregular, there being observable a slight outward enlargement of the pupillary margin above the horizontal axis. This state of the pupils continued to the end. He gradually sunk, but, though dull and heavy and occasionally passing urine and fæces involuntarily, he retained consciousness till within a day of the fatal issue; partook of bread and milk, and put out the tongue when roused by shaking and urged in a loud voice to do so. As before stated the pulse rose to 140 the day before death. All efforts to induce mercurial action failed, and he died on June 26th, eleven days after admission, and on about the twentieth day of his disease.

On post-mortem examination considerable vascularity of the membranes of the brain was observable, there was slight general serous arachnoid effusions, but it was in the circle of Willis that most marked lesion was noticed. The arachnoid in this situation was opaque from greenish-yellow gelatiniform exudation. On opening the lateral ventricle there was a very considerable escape of slightly reddish serum.

Dr. Lyons observed on the marked similarity of the two cases just recorded as to the symptoms presented during life and the post-mortem appearances, the obstinately rebellious nature of the disease, and the total failure of all modes of treatment employed. In the latter case especially the continuous serous drain by vesication of the scalp which was most efficiently maintained for several days might have been expected to act beneficially as a direct derivative; but though slight improvement seemed apparent at first, no permanent result was obtained. The very limited amount of the gelatiniform exudation in the circle of Willis was likewise worthy of note. Viewed in connexion with the limitation of the effects of pressure to the production of paralysis of the constrictive fibres of the iris while sensorial functions and motor power remained intact until almost the last in the nerve filaments of the other intra-cranial nerves, it offers no little difficulty of interpretation in the phenomena presented during life and after death.

Dr. Lyons observes that where the sympathetic filaments as well as the second, third, fourth, fifth, and sixth pairs of nerves lie so close together in and near the circle of Willis, that they all become involved in the same mass of gelatiniform exudation, the intra-cranial nerves, from their firmer texture and sheath-like investment, may be presumed to be capable of resisting an amount of pres-

sure which proves fatal to the integrity of functions of the more delicate and less protected filaments of the sympathetic. It is, of course, presumable that other function of the sympathetic within the cranium are likewise impeded, but the filaments to the ciliary ganglion, and through them the constrictive fibres of the iris, are the only ones the paralysis of which becomes ordinary cognizable externally. Interference with the functions of the sympathetic filaments and consequent dilatation of one pupil by a pressure which may not derange for the time other nerve fibres is familiar to practical physicians in the study of the symptoms of aneurism.

Persistent partial dilatation of right pupil without discoverable cause.—This case may be noted in a few words. The patient was admitted to the Hardwicke Hospital labouring under typhoid fever, through all the phases of which he progressed, but without very marked head symptoms, and finally, after about six weeks' sojourn in hospital, fully convalesced. When convalescence was fairly established, but not previously, it was noticed that the right pupil was about twice the size of the left, but in other respects normal. No positive defect of vision existed, nor to the ophthalmoscope was any lesion observable, although sight was not quite so far in that as in the other eye. A most careful exploration was made with a view to detect latent aneurism or any other morbid condition, but with entirely negative results, and the patient left hospital unconscious of any impairment of vision or morbid condition of any kind.

Proceedings of Societies.

HARVEIAN SOCIETY OF LONDON.

MAY 17TH.

Dr. TYLER SMITH, President.

DR. RICHARDSON'S LOCAL ANÆSTHESIA.

DR. RICHARDSON, at the request of the President and members of the Harveian Society, explained to the Society that the effect of his ether apparatus was probably entirely due to the cold generated by the rapid evaporation of the ether. The action of cold in thus producing insensibility was due, he thought, to the fact that the force of sensation in different parts was brought down by the blood. When we touched a part more motion was produced, and consequently more sensation. He did not believe in compound nerves of sensation. When a part was frozen the blood could not supply sufficient heat to keep up the sensation of the part. Nerve force was brought down by every contraction of the heart. As a verification of this view he mentioned that local anæsthesia could be much more rapidly obtained, if, whilst cold was applied, the vessel leading to the part were compressed. Thus when the toe nail is removed pressure should be made on the anterior tibial artery, and thus we are enabled more rapidly to produce complete absence from pain. With regard to the apparatus required for operation, he generally carried about with him a three-division bottle, having three jets near each other, and all fitting together in a leathern case. By means of this apparatus the operation of Cæsarean section had been painlessly performed, and a tumour on the back, requiring an incision of seven inches, had been removed by Mr. Adams. When a part is to be frozen, it should be previously carefully and perfectly dried, otherwise a film of ice formed and obstructed anæsthesia. This was the reason of the difficulty in operations of dentists. In some cases hoar-frost is deposited on the surface of the part, but anæsthesia may be obtained even in such cases. If alcohol or chloroform were added to the ether hoar-frost appeared. The test for the purity of the ether consisted in finding whether it would boil when poured into the palm of the hand. This could be ascertained by holding the hand

near the ear and listening. One caution he would give—the use of chloroform had introduced a certain carelessness into operations, the operator would sometimes talk and observations were made, which might cause, as he had witnessed, syncope of the patient. Now that anæsthesia was local, solemn silence should be maintained. At first it had been thought that the process was only suitable for small operations; but ovariectomy had now been performed four times successfully. Amputations of half the foot, too, had been performed; operations for strangulated hernia had been performed three times with complete success; something, too, had been added in the last case, since the cold sometimes caused the hernia to become reducible. In Cæsarean section the advantages of the process were enormous. (1) There was no bleeding—a circumstance which used to render the operation extremely hazardous; (2) The cold made the uterus contract. Amputations of the thigh had not been tried. When there was any doubt chloroform ought to be used; but in cases of cardiac disease requiring amputation of the thigh, he would not hesitate to use it. A single jet did well for carbuncle. In whitlow the application was most useful, sometimes it will cure the complaint. In the last stage if the artery of the finger were compressed and cold frequently used the complaint could be cured in three days. There was sometimes a little pain felt in applying the spray to the hands or forehead. He had not yet seen sloughing follow on its application. In Bright's disease blistering of the skin was produced. With regard to its use in medical cases, whenever the pain was thoroughly local, freezing would relieve it. In cases of conjunctivitis it had proved of service. He had recently made use of a styptic ether for surgical operations and found it of great service. The ether was mixed with xyloidine, or starch dissolved in nitric acid. In the case of a young gentleman of a hæmorrhagic diathesis who had nearly bled to death from the extraction of a molar tooth, he first froze the part and then plugged it by the styptic, so that the bleeding was completely stopped.

Mr. ADAMS said the Society were deeply indebted to Dr. Richardson for thus explaining his great discovery to them. He had found that large operations might be performed with the aid of this apparatus with perfect success, provided that plenty of time were taken and no rapidity of operative procedure aimed at. Thus he had recently removed a large tumour requiring an incision of seven inches without any pain being felt. In tenotomy it was all that was needed to cause absence of pain. Wounds healed as well after the use of the process as when any other was used. In one case only had he seen any sloughing after its use; it was in an ulcer which had been subcutaneously incised after Mr. Gay's plan.

Dr. DRYSDALE had found Dr. Richardson's discovery most serviceable in many cases in which he had used it, and especially in touching large specific secondary sores with strong nitric acid. This was done without any pain either at the time or afterwards by freezing the part. He would be glad to hear from the illustrious discoverer whether the frequent surgical operation of tooth extraction was likely soon to be rendered painless by this means.

Mr. BENSON BAKER asked whether the process had been applied to the suppressing of post-partum hæmorrhage by means of some contrivance for locally applying the ether spray to the uterus.

Mr. ISAAC BAKER BROWN, junior, said that Dr. Richardson claimed for the ether process that it first prevented bleeding, next shock, and thirdly, produced contraction of the wards in the operator for Cæsarean section. But if the bleeding were stopped, did we not diminish the vitality of the child; and, again, he would ask, what was the result of the cases of ovariectomy? Did the cases recover? If not, what was the cause of death in any of them?

Dr. HAUT VINEN said he had been present during the operation of Cæsarean section referred to, and the patient, whom he had seen several times, was now quite well.

Dr. RICHARDSON said that he believed use might be made of this application in post-partum hæmorrhage. As to any danger from the use of the ether spray in ovariectomy, this was groundless. So volatile was the ether that we cannot even swallow it if we would. He had often asked himself whether this plan might not prove an anæsthetic in labour pains. He believed it would be found to diminish the pains of labour if the spray were allowed to play on the sacrum during the pains. As to tooth-drawing, there was no difficulty in extracting the upper teeth without pain. But in the back and lower teeth there was difficulty, because of the saliva becoming frozen. In one case he had applied cold to the cheek, and had thus caused painless extraction of the teeth. The whole operation of Cæsarean section only occupied two minutes, and thus could not have injured the child whilst bleeding was absent.

The PRESIDENT said it would not be just to the spray to use it internally in post-partum bleeding. Admission of air to the great uterine sinuses was so much to be dreaded as to render it likely to cause sudden death. Cold water used over the uterus externally was of great benefit in such cases, and doubtless the ether spray would be even more useful for the purpose of producing contraction of the uterus by external application.

ENTIRE DISLOCATION OF THE CLAVICLE.

ON January 26th, 1868, Dr. N. L. North of Brooklyn, New York, was called to see a boy of about fourteen years of age, who had been thrown backwards from a stool or slight eminence, upon which he had been placed, and came down striking with his whole weight upon the back of his left shoulder. Upon examination, Dr. North found the shoulder depressed and thrown forwards; the centre of the clavicle fallen in as if fractured, with an abrupt rounded prominence at the sterno-clavicular articulation, and a sharp prominent ridge on the top of the shoulder, standing three-fourths of an inch above the superior point of the acromion process, and running from that process towards the neck, for about an inch, then gradually tapering down to the usual form of the neck. The boy complained of a great amount of pain and considerable difficulty of breathing. Dr. North concluded from his examination of the case, that there was an entire dislocation of the clavicle without fracture, both ends, with of course the entire bone, having been forced out by the force of the blow or fall upon the shoulder, and then drawn half way over forwards and downwards by the large pectoral and deltoid muscles. The round prominence in front was caused by the turning out of the sternal end of the bone, and the sharp ridge on the top of the shoulder was caused by the turning up of the trapezoid portion, while the depression in the centre was the effect of the turning down of the convexity at the middle portion of the clavicle. The shoulders having been forcibly thrown backwards, and retained in position with long strips of adhesive plaster applied in the form of the figure-of-8 bandage, compression with the right thumb and finger, backwards and downwards upon the trapezoid portion of the clavicle, and at the same time, with the thumb and finger of the left hand upon the sternal end of the bone, firm pressure was made upwards and backwards. Dr. North felt the ends of the bone return to their normal positions, the proper shape and symmetry of the parts being completely restored. He applied compresses successively to each end of the bone, retaining them by means of adhesive straps; and applied Day's "neck-yoke" apparatus for fractured clavicle. In the course of two weeks he commenced loosening the dressings, and at the end of three weeks he removed them altogether, and discharged the patient well.—*New York Medical Record.*

ACCORDING to the report of the directors, lately given, of the Asylum for Idiots at Earlswood, there were 404 patients at the beginning of the year, and 421 at the end showing an increase of 17.

Foreign Medical Literature.

TWO CASES OF TUMOUR OF THE BRAIN, WITH REMARKS ON THE CONNEXION BETWEEN CEREBRAL TUMOURS AND AFFECTIONS OF THE RETINA AND OF THE OPTIC NERVE.

By W. KOSTER.

Translated from the *Nederlandsch Archief voor Genees- en Natuurlunde*, 1e Deel, 4e Aflevering, Utrecht, 1865.

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

(Continued from page 686.)

c. *Connexion between tumours in the brain and blindness.*

THAT a serious organic affection of the brain, giving rise to paralysis of different parts, may also lead to blindness and other disturbances of the senses, has long been known. But while, previously to the treatise of A. v. Graefe, the removal of the function of a central part, whether by pressure or by softening, was looked upon as the cause of these lesions of the senses, ophthalmoscopic investigation exhibited changes in the papilla of the optic nerve and its surrounding, which are quite sufficient to account for the amaurosis. Without wishing to deny the existence of diminution or loss of the power of vision from a central cause, independently of alteration of the optic nerves and of the retina, without even being able to decide with certainty whether in the cases described by me, without any affection of the eye, the power of vision would have suffered, the ophthalmic lesion is evidently of the greatest importance, and the question of the connexion between the cerebral tumours and the ophthalmic affections at once suggests itself.

One word as to the nature of the changes perceptible in examination with the ophthalmoscope may still be premised. In the first case observed by von Graefe, and in which he, even before examining the eye, from the other symptoms suspected the existence of a cerebral tumour, the idea of pressure, or in general of paralysis of the optic nerves occurred to him, and he thought he should find "no material change in the eye, or only the signs of secondary atrophy of the optic nerves at the papilla." To his amazement he found "the papilla very considerably and irregularly swollen; it rose abruptly on the one side, to return on the opposite to its proper level. The otherwise transparent substance appeared turbid with an unusually strong admixture of red, as did the adjacent retina, whereby the choroidal boundary of the optic nerve was completely effaced. The retinal veins were dilated, unusually tortuous, very dark in streaks, stood out irregularly in the opaque substance, the arteries were proportionally slight."

As to the extent of the affection, it "diminished continually from the boundary of the optic nerve, and comprised on the whole a zone of rather more than 2" in breadth."

On dissection in this case a large sarcomatous tumour was found in the right hemisphere. In the latter weeks of the patient's life the swelling of the papilla of the optic nerve had disappeared, but the papilla itself had remained quite white; tortuous vessels and the turbidity of the retina around the papilla still always distinguished the appearance of the affection from that of ordinary atrophy of the optic nerve in cerebral amaurosis.

Von Graefe subsequently observed other similar cases, which are mentioned in the treatise above referred to. In some he found around the papilla of the optic nerve, at

first, slight ecchymoses, which at a later period again disappeared. Some of the eyes were examined by Schweigger, others by Virchow. Their results agreed tolerably well. Both found hypertrophic thickening, around the papilla, of the connective tissue-stroma of the retina, and in the same elongated cells with nuclei were observed. The nerve fibres were thickened. Somewhat farther from the papilla Seidel found among the radiating vessels round, homogeneous bodies without any distinct membrane and without nuclei. In radiating sections the bodies seemed to lie in the layer of the nerve fibres.

If we compare these cases with the two described by me we observe, with very great analogy, some points of difference, particularly in the first case (sarcoma cerebri). It is remarkable, that during life, on ophthalmoscopic examination, no other change than atrophy of the optic nerve, *papilla alba*, was recognized. Neither vascular congestion, hæmorrhage, nor opacity of the retina was here observed. Thus both what was seen during life, and the results of examination after death, agree with what usually takes place after paralysis of the optic nerve from a central cause, but without those great tumours, which produce such an increase of pressure within the cranium. And, nevertheless, this increased pressure constantly existed in this case in the highest degree. But besides the tumour distention of one lateral ventricle was present.

Another point which must be looked upon as of the greatest importance, is the dropsical distention of the sheath of the optic nerve within the orbit.

Von Graefe (*l. c.*, p. 64) looks upon the connexion between the affection of the optic nerve and the cerebral tumours as "entirely mediate," dependent on "the pressure, which such tumours exercise on the sinus cavernosus." Accumulation of blood in the retinal vessels, distention and tortuosity, swelling of the papilla, &c., he refers thereto. But he immediately adds: "The presence of actually inflammatory phenomena is attended with somewhat more difficulty." The mechanical hyperæmia is not sufficient for this; but both in the effusions of blood, and in the irritation of the fibres of the optic nerve "within the unyielding scleral ring," von Graefe thinks the cause of the essential nutritive changes are to be sought.

We can quite agree in this idea, and apply it wholly to the second case, where actual retinitis and swelling of the papilla of the optic nerve existed, as the histological investigation after death showed. In the first case we find in the dropsical effusion within the sheath of the intra-orbital part of the optic nerve evidence of the obstruction to the return of the blood (pressure on the cavernous sinus) from the orbit, and moreover a proof of the correctness of von Graefe's views respecting the interference with the optic nerve, in its swelling, by the firm boundaries surrounding it. But while in von Graefe's theory the margin of the sclerotic (the situation of the so-called lamina cribrosa) impedes the distention of the fasciculi of the optic nerve, in our case, as it appears, the foramen opticum was the place where the nerve was compressed. In this instance, too, the contrast between the strongly flattened portion of the nerve in the cranial cavity and the swollen dropsical part within the orbit was very striking.

This pressure and modified nutrition through impeded circulation produced the atrophy and slight degeneration of the scleral extremity of the optic nerve, and of the neighbouring portion of the retina, which manifested themselves during life, on ophthalmoscopic examination, as *papilla alba*. But why were the peculiar inflammatory phenomena, so distinctly present in the second case, absent in this one? We must evidently assume in the second case the existence of an accessory cause for the important inflammatory changes, which was wanting in the first. But the purely mechanical cause was in this instance present certainly in a greater degree than in the second.

As to the nature of this hypothetical cause we can venture only on conjectures. The reason why the papilla of the optic nerve suffers less, lies probably in the greater extensibility of the sclerotic tissue at so early a period of life (the child with sarcoma cerebri was only 7 years old), while the result of the obstruction to the return of the blood could manifest itself only as a dropsical effusion around the whole intraorbital portion of the optic nerve.

In any case, therefore, we must assume the existence of two different causes for amaurosis with cerebral tumours. The compression of the optic nerves and the impeded return of venous blood from the retina may, both by interrupting the conduction, and by changes in the circulation with hyperæmia and effusion (on which again granular change and the deposition of fat in the papilla depend), completely remove the function of the retina and of the optic nerve, changes which do not essentially differ from those of atrophy of the optic nerve from other cerebral causes. But in the second place, upon the results of mechanical obstruction an inflammatory process around the papilla of the optic nerve, so highly developed in our second case, may supervene. Although this is not in all points cleared up as to its origin, it may probably be deduced from the irritation caused by the vascular dilatation and minute extravasations of blood, though partly according to von Graefe's idea, from the actual condition of the place, where the optic nerve perforates the sclerotic.

Utrecht, March 5, 1865.

ACTION OF OXYGEN ON THE BLOOD.

By M. SCHOENBEIN,

PROFESSOR OF CHEMISTRY IN THE UNIVERSITY OF BALE.

Translated by THOMAS WHITESIDE HIME, B.A. Dub.

(Continued from Vol. i., page 668.)

If during respiration no peroxide of hydrogen be formed, it is impossible to conceive why the blood-globules possess the power of decomposing that substance. If, on the other hand, we start with the hypothesis, which so many analogies concur in strengthening, that neutral oxygen on its entry into the blood is decomposed into antozone and ozone, and thus produces peroxide of hydrogen, it is quite patent why the blood-globules possess in such a high degree the property of decomposing HO_2 .

Experiment proves that oxygenated water is indifferent to albumen, as to many other organic substances; whence it follows that the part of the inspired oxygen which is transformed into antozone, and combines with HO to form HO_2 , would be useless in the organism if that antozone combined with water did not undergo some modification to render it fit to act a part, chemically, and physiologically in the organism—that is to say, if it did not become capable of producing oxydation. In my opinion it is the blood-globules which chiefly produce this, and their property of decomposing oxygenated water, like platinum, makes them fit to modify suitably the antozone combined with water in HO_2 .

The theoretic importance of these questions, and the novelty of the views here advanced on the principal duty of the blood-globules, necessitate treating the subject at length, in order to make it thoroughly comprehended. It is better to be rather long and clear than concise and obscure.

The above experiments prove that the blood-globules undergo a chemical modification when they decompose peroxide of hydrogen: and this modification arises without doubt from their taking up a portion of the oxygen of that substance. If, however, as I have asserted, the antozone of HO does not oxydise albumen either liquid or solid, there is very little probability that this antozone can oxydise the blood-globules. By what, then, is this oxydation produced? To answer this question it is necessary to revert to the explanation I gave some years ago of the decomposition

of oxygenated water into neutral (ordinary) oxygen and water. Ozone, whether free or in combination, as found for example in peroxide of lead, peroxide of manganese, &c., forms readily with tincture of guaiacum a compound of a deep blue colour. Antozone united with water, oil of turpentine, &c., is quite indifferent to this tincture, and does not turn it blue. If, however, to tincture of guaiacum united with HO_2 , a small quantity of spongy platinum deprived of air, and for this purpose preserved under alcohol, be added, the tincture becomes deeply coloured, similarly as under the influence of peroxide of lead or manganese, or of permanganic acid, or of other oxygenated combinations, to which I have given the name of ozonides.

My experiments have shown further that solid pyrogallic acid becomes oxydised, even at a low temperature, by free ozonised oxygen, and becomes transformed into certain deeply coloured substances, known by the name of ulmics. If the action of the ozone continue it burns away entirely, and it is for this reason that pyrogallic acid is one of the most sensitive reagents of ozone. Experiment has proved that all oxygenated combinations which turn tincture of guaiacum blue, turn an aqueous solution of pyrogallic acid brown.

I have shown that peroxide of hydrogen can dissolve pyrogallic acid without causing the least oxydation of that substance which ordinarily oxydises so readily, the solution continues uncoloured, which proves strongly the indifference of the two substances to one another. But if to this solution be added the least trace of platinum black it rapidly becomes brown, which also takes place in an aqueous solution of pyrogallic acid when it is brought into contact with free ozone or an ozonide—e.g., peroxide of lead, permanganic acid, &c. From whence we may conclude that when in contact with platinum, the antozone of peroxide of hydrogen is transformed into ozone, and that it is the latter which produces the blue colour in tincture of guaiacum and the brown colour in pyrogallic acid.

But if platinum possesses the property of communicating to the antozone of peroxide of hydrogen the chemical activity of ozone—that is, if it can transform antozone into ozone, it must also possess the property of changing $\text{HO} +$ antozone into water and neutral oxygen. My experiments have proved that free ozone and the ozonides—e.g., peroxide of lead and permanganic acid—produce this decomposition. In fact, when a molecule of antozone belonging to a molecule of peroxide of hydrogen in contact with platinum has been transformed into ozone, this new molecule will combine with the antozone of the nearest molecule of oxygenated water to form neutral oxygen, which, being no longer able to remain in contact with HO , will escape in consequence of its gaseous form. As free ozone cannot unite directly with platinum, we conclude it undergoes no oxydation, and is not chemically altered during the decomposition of the peroxide of hydrogen.

I have already shown above that the blood-globules possess in a very high degree the power of turning tincture of guaiacum mixed with oxygenated water blue, and a colourless solution of pyrogallic acid, containing HO_2 , brown. From thence I conclude that the blood-globules possess, like platinum, the property of transforming the antozone of peroxide of hydrogen into ozone. As the blood-globules also decompose HO_2 into water and neutral oxygen, we are naturally led to explain this phenomenon in the same manner as the decomposition of HO_2 by platinum. There is, however, this great difference between the metal and the globules that platinum is entirely indifferent to ozone, while the globules readily decompose under its influence. It is, then, not surprising that the globules undergo a chemical transformation while decomposing peroxide of hydrogen; and this appears less strange when we observe that in transforming the antozone of $\text{HO} +$ antozone into ozone, they can produce, besides their own oxydation, that of other organic substances—e.g., of pyrogallic acid.

It is well known that there is always in the animal organism a certain amount of blood-globules in a state of formation, whilst others are in a state of disintegration. Their destruction is, I consider, very probably due to oxydation. If, in accordance with my hypothesis, respiration causes a continuous formation of peroxide of hydrogen in the blood, the globules should become modified by it, as they do by artificial oxygenated water. In other words, the blood-globules, in transforming the antozone of the peroxide of hydrogen which arises in the blood into ozone effect their own oxydation, and change into another albuminoid substance (fibrin?), and thus, perhaps, perform the most important part of their physiological rôle. It is, however, probable that, under the influence of the blood-globules, other oxydations are produced, as that of albumen, of certain tissues, &c., for if these globules can render the positive oxygen of the oxygenated water fit to oxydise the resin of guaiacum and pyrogallic acid, it would be hard to imagine that these are the only organic substances which undergo an analogous change under the same conditions. The blood-globules might still act in a third manner. If, for example, all the antozone of the peroxide of hydrogen contained in the blood was not employed in oxydising the globules which convert it into ozone, as well as other organic substances, if there remained an excess of ozone, this would combine with a portion of the antozone of the undecomposed oxygenated water to form neutral oxygen. This could in turn be decomposed into antozone and ozone, like the inspired oxygen, and thus become fit to produce further oxydations; but as the quantity of oxygenated water which exists at any given moment in a determined portion of the organism must be very small in proportion to the blood-globules, it is probable that this combination of antozone with ozone never occurs, or only to a very small extent.

If, as results from the preceding facts, we refer the oxydations which take place in the animal body to the transformation of neutral inspired oxygen into antozone and ozone, the question arises, from the influence of what part or parts of the blood does this transformation take place. In my memoir, "On the Formation of Peroxide of Hydrogen at elevated Temperatures," and in others, it has been shown that the condition most essential to the chemical polarization of neutral oxygen is the presence of two substances, one of which has an affinity for antozone, the other for ozone; but many of my latest experiments prove that water is the substance which has the greatest affinity for antozone, with which it forms peroxide of hydrogen. We know, too, that a large number of organic and inorganic substances unite with extreme avidity, and even at low temperatures, with ozone, and become oxydised under its influence. Such, in my opinion, is the manner in which a large number of oxydations are produced, which occur at the ordinary temperature in presence of water with formation of oxygenated water, and which seem resultant from neutral oxygen.

The organic substances which form the chief constituents of the blood—albumen, fibrin, and globules—may be classed as substances which absorb ozone artificially prepared with greater or less avidity. As water, too, is found in the blood, this liquid (the blood) presents the conditions essential to the transformation of neutral oxygen into ozone and antozone. But experiment shows that the blood-globules seize on ozone and become oxydised incomparably quicker than albumen or fibrin. From this we are induced to admit that they in presence of water transform the inspired oxygen into antozone and ozone. Some years ago I carefully compared the slow combustion of phosphorus in air with animal respiration, as regards the modifications which the active oxygen undergoes in these circumstances. The results of my latest experiments on the oxydation of organic and inorganic substances in moist air have only confirmed my first opinion. Phosphorus becomes oxydised, in fact, at very low temperatures under the influence of ozone, while oxygen cannot

combine with it under the same conditions. In the ordinary language of chemistry phosphorus has a great affinity for ozonised oxygen, while it has none for ordinary oxygen.

Water, which is equally indifferent to neutral oxygen, is remarkable for its great tendency to form with antozone, peroxide of hydrogen. It is for this reason that water acts with phosphorus, which has an affinity for ozone, to transform, or rather decompose, neutral oxygen into ozone and antozone; in consequence of which decomposition the antozone unites with water to form peroxide of hydrogen, and the ozone goes to the phosphorus to form PO_2 and PO_3 , while at the same time free ozone is produced.

The oxydisable matters in the blood, and especially the globules, may be compared with phosphorus in their property of polarizing oxygen. Thus will be seen why I attribute to the water in the blood the same rôle as in the slow oxydation of phosphorus. If this latter body, or the acids derived from it, possessed, like platinum and blood-globules, the property of changing into ozone the antozone of the peroxide of hydrogen, which is produced during the slow combustion of phosphorus, we would find no peroxide of hydrogen in the water which surrounds this substance, as we do not find it in the blood.

If there were in the animal organism, besides the blood-globules, other substances—e.g., tissues, acting like platinum on oxygenated water, it would follow, from the preceding facts, that these tissues would produce the same physiological effects as the globules; oxydations would be produced in other parts of the body. There are certain facts which justify this hypothesis.

If a few drops of subacetate of lead be added to a relatively large quantity of oxygenated water, first peroxide of lead is formed, which acts immediately on the oxygenated water not yet decomposed, reduces it to the form of water HO, and is itself converted to the form of protoxide, PbO. There is evidently a disengagement of neutral oxygen.

The peroxide of lead I consider a combination of ozone and protoxide of lead $PbO +$ ozone, and oxygenated water as a combination of water and antozone, $HO +$ antozone: I admit, consequently, that in the circumstances just mentioned the antozone of one part of the free peroxide of hydrogen is converted into ozone, which forms peroxide of lead with a part of the base of the salt of lead. But peroxide of lead is an ozonide and cannot exist in presence of an antozonide HO_2 ; the ozone of one and the antozone of the other unite to form neutral oxygen, while the two peroxides become water HO, protoxide of hydrogen and protoxide of lead, PbO.

But if subacetate of lead possesses the property of converting the antozone of peroxide of hydrogen into ozone it would naturally follow that it should turn a mixture of tincture of guaiacum and HO blue; and this in fact is the case.

The oxydation of indigo blue dissolved in sulphuric acid, and its transformation into isatin $C_{16}H_5NO_4$, under the influence of free ozone or the ozonides, as, for example, $PbO +$ ozone; $Mn_2O_3 + 5$ ozone, &c., are well-known facts; we know, on the other hand, that tincture of indigo is very slowly decomposed by $HO +$ ozone. But if a small quantity of subacetate of lead be added to oxygenated water coloured by tincture of indigo the mixture instantly becomes decolorized. Oxygenated water largely diluted with water is incapable of turning blue a mixture of starch paste and iodide of potassium; while ozonised or oxygen the ozonides—e.g., peroxide of lead—permanganic acid, produce this coloration immediately and in a very marked manner. If to an uncoloured mixture of peroxide of hydrogen starch paste and iodide of potassium, a single drop of subacetate of lead be added the mixture instantly turns a deep blue; so, too, does starch paste, saturated with iodide of potassium, when it is added to a solution of basic acetate of lead, which is one of the most delicate reagents of oxygenated water.

If a solution of a salt of protoxide of iron (e.g., a

solution of sulphate of the protoxide of iron) be mixed with a sufficient quantity of oxygenated water, the base of the salt becomes a peroxide, a part of which precipitates as basic salt. My experiments prove that the salts of peroxide of iron produce numerous oxydations which free ozone and the ozonides only are the cause of: thus they turn blue tincture of guaiacum. Further, peroxide of hydrogen can in favourable circumstances convert peroxide of iron to protoxide; as, for example, when H_2O_2 is made to act on a mixture of a solution of a salt of peroxide of iron and ferrocyanide of potassium, this reduction is accomplished with disengagement of neutral oxygen and formation of a precipitate of Prussian blue. From all these facts we may conclude that the third equivalent of oxygen in peroxide of iron is ozone, and consequently that protoxide of iron, even in the state of combination with an acid possesses the property of changing the antozone of peroxide of hydrogen to ozone. The truth of this conclusion is confirmed by the following facts: tincture of guaiacum containing peroxide of hydrogen, and starch paste, saturated with iodide of potassium and mixed with oxygenated water, are instantly coloured by the smallest trace of sulphate of the protoxide of iron in solution; similarly, peroxide of hydrogen, coloured blue by sulphate of indigo, becomes instantly decolorized under the influence of solution of sulphate of iron.

If, now, the preceding reactions of subacetate of lead and of the salts of peroxide of iron be compared with those exhibited by the blood-globules in the same circumstances we are struck by their similarity. Further, experiment has proved that the blood corpuscles act on tincture of indigo mixed with H_2O_2 similarly as on starch paste containing this same peroxide in presence of iodide of potassium.

In termination, this memoir has been published chiefly with the object of calling the attention of physiologists to a subject which should possess much interest for them, and the study of which the chemist cannot extend much further without their aid from want of the necessary physiological information; I freely admit I find myself in this position.

Reviews.

APONTAMENTOS ACERCA DAS ECTOCARDIAS A PROPOSITO D'UMA VARIEDADE NAO DESCRIPTA. *A Trochocardia Lidos na Academia Real Das Sciencias de Lisboa, pelo Socio Effectivo.* By Dr. Pedro Francisco da Costa Alvarenga, Medico Honorario da Camera da sua Magistrado el Rei D. Luiz.*

WE hail with pleasure this interesting and elaborate communication from the pen of our accomplished colleague, Dr. Alvarenga, who, to his other claims on our notice, adds that of being editor-in-chief of the *Medical Gazette of Lisbon*. Dr. Alvarenga, not satisfied with the narrative of his own interesting observations on a new and hitherto undescribed form of cardiac displacement, has published a valuable contribution to the literature, nomenclature, and general history of cardiac displacements. With an inexhaustible assiduity of research he has run through the whole range of ancient and modern medical literature bearing on the subject, and in his valuable paper, read before the Academy of Lisbon, and published under the auspices of that learned body, furnishes us with facts and notices gathered from the writings of the Greek and Latin fathers of medicine, the mediæval authorities and those of our own times.

In his preliminary observations he takes exception to

* Observations on Displacements of the Heart, with an account of a New Variety of Dislocation of the Organ. By Dr. da Costa Alvarenga, Honorary Physician to His Majesty Don Luiz, &c. &c.

the very unscientific classification and nomenclature of the conditions of cardiac displacements hitherto recorded, and for the term *ectopia cordis*, employed by Breschet and others, and which harmonizes ill with the terms *dexiocardia*, *hernia of the heart*, &c., proposes a uniform nomenclature to include all varieties, and based on homonymous Greek derivations for all the subdivisions. His views and classifications are thus represented:—

Ectocardia	Intrathoracica	{	Lateral	{	Dexiocardia.	
				{	Aristrocardia.	
				{	Trochocardia.	
	Extrathoracica or cardiocele	{	Central	{	Mesocardia.	
					{	Epicardia.
					{	Hypocardia.
					{	Thoracica.
					{	Abdominalis.
					{	Cervicalis.

Cardiac displacement was not unknown to the great observer of Cos (Hippocrates). In more recent times Cardan, and subsequently Riolanus, record examples. A remarkable instance is that observed by Riolanus in the person of Queen Mary de Medicis. He states: "Rarum est, sed non lethale, si cor feriat latus dextrum pectoris et situm mutet. Id visum in quadragenario, qui sanus ad hoc tempus vixit, et hoc vidi in Regina Matre Regis Lud. xiii." In the variety which he has himself specially noticed, and which he terms *Trochocardia*, Dr. Alvarenga describes two displacements of the heart; one consists in the falling down of the base of the organ, by which it assumes a horizontal position; the other depends on the rotation of the heart upon its own axis, which is now horizontal, and in such a manner that the right ventricle is placed upon the left. On post-mortem examination the heart was found twisted on its axis, the right border being pushed forward, the anterior part of the right ventricle being uppermost, and the posterior surface of the right ventricle below; the origin of the pulmonary was hardly visible, being to the left side and posterior to the aorta. In this case great dilatation of the right auricle would seem to be regarded by the author as the strict cause of the displacement. Other observations, with autopsies, follow, in which the mechanical bearings of the dislocation are fully discussed. In several instances tracings of the pulse-wave by the sphygmograph of Marey are given, and to those interested in the subject of cardiac displacements, the whole memoir will prove of much value. It is in all respects an important contribution to cardiac pathology.

A SINGULAR RECOVERY FROM CHOLERA.—The following singular fact is related by the *Mémorial d'Amiens*, in speaking of the cholera:—"During the summer of 1848, towards the end of June, the epidemic reached Brussels, where it attacked, one Sunday in the forenoon, General Chazal, Minister of War, who gradually sank, and by eleven on that night was in an almost hopeless state, notwithstanding the attendance of four medical men, including Dr. Seutin, the first surgeon of Brussels, and Dr. Varlet, a celebrated homœopathic practitioner. At eight the following morning all was considered over, the face having assumed a blue tinge, and the pulse having ceased, so that the general's death was communicated to the Royal Family and announced in the public journals, whence it was copied throughout Europe. Meanwhile, an accidental reference by General Jomini, before the attendants in the sick chamber, of a remedy had recourse to in Russia, where sacks filled with hot ashes were placed on the body of the patient, induced the general's aides-de-camp to try the plan, and after six hours of incessant perseverance the remedy proved efficacious, the body resuming its natural hue, and animation being restored. The general subsequently recovered, and is still Minister of War in Belgium."

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 4, 1866.

THE POOR-LAW INSPECTORS AND THE SICK POOR OF LONDON.

WE have often expressed the opinion that in the recent revelations which have been made as to the treatment of the sick poor in the metropolitan workhouses, the evidence has shown that the Poor-law Board itself is quite as much to blame as the local Guardians. We cannot too often repeat that the Poor-law Board has an absolute control over the management of the poor, including of course the sick poor, in this country, and that it ought to have made itself acquainted with the abuses which a voluntary association has lately taken upon itself to disclose and denounce. This opinion is now expressed by the *Times*, as well as by some other papers, which have expressed, in very forcible language, their disgust and horror at the condition of most of the sick wards of the workhouses, and at the neglect and ill-treatment of which the sick are the victims.

The last investigation of the nature to which we allude has been into the management of the sick poor in the Paddington Workhouse, which, we are told, is one of the best in the metropolis, and, as far as the construction of the building is concerned, we believe this commendation is not altogether unmerited. But as to the sick poor themselves, we have the same old story of inattention, neglect, overcrowding, want of classification, not to say wilful cruelty, with which the public mind has lately become so familiar.

In this workhouse—one of the best, be it remembered, in our great capital, and itself located in one of our most opulent and populous quarters—we are told that in one of the wards as many as three children slept in a bed, or even sometimes five had slept together. Of the three sleeping in one bed at one period, one of the children had inflamed eyes, another chicken-pox, and a third water on the brain. There is no classification of the sick, but the old women subject to fits, and sick children, and the acutely sick and the chronically sick are all indiscriminately herded together. The paralytic patients fall out of bed because there is no nurse to help them, and the epileptic and idiotic roam about the wards, fall down upon the floors, or disturb the other sick persons by their cries and moans. The nurses, so-called, are chiefly if not entirely paupers, many of them very aged, entirely ignorant, addicted to drink, and practised in no arts except stealing and extortion.

A lady visitor comes forward and corroborates most of these statements, deposes to the indiscriminate mixture of the sick, irrespective of the nature of their disease; to the unfitness of the pauper nurses for the duties imposed upon them; to the neglect of the proper warding

of the pauper lunatics, who disturb the sick both by night and day; to the venality of the unpaid nurses, and to the overtaxing of all the paid staff. To these charges no substantial defence is offered on the part of the Guardians, and although a barrister appeared on their behalf he brought little evidence to disprove the assertions made, and failed to elicit by cross-examination any facts of the slightest avail to his clients.

But the most amusing feature of the whole affair, if anything can be amusing where there is so much to horrify and disgust, was the speech of Mr. FARNALL, the presiding Poor-law Inspector, who volunteered a speech in justification of himself and of his neglect in discovering the existence of the abuses described in evidence. He had, it seems, very recently "inspected" this very workhouse, in company with a Medical Officer, with instructions from the Poor-law Board, but had failed to detect anything wrong in the general arrangements, and he very *naively* complains that neither the paupers themselves nor the paid officials gave him any information as to the facts subsequently deposed to. The indisposition of the paid officials to say more than they were compelled to say may perhaps be explained by the fact alluded to in the report of the proceedings, that the one paid nurse who *did* give information to Mr. FARNALL and Dr. SMITH, was immediately dismissed from her post, and, as is alleged, for so doing; and no doubt if the Medical Officers had deviated from their usual taciturnity, or had said anything except in laudation of the Guardians, they would have shared the same fate. Without alluding to the nurses, we may observe generally that the Medical Officers of such institutions exercise a wise discretion in saying as little as they can to a Poor-law Inspector, for if they reveal the secrets of the prison-house to that functionary they are liable to dismissal by the Guardians, and if they remonstrate unsuccessfully with the latter they are bound, according to the ingenious reasoning of one of our Medical contemporaries, to relinquish their post. The result of such proceeding would of course be to introduce successors more subservient and less conscientious than themselves, and thus to perpetuate the abuses which are now proved to exist.

As for a Poor-law Inspector, it would appear that he is a kind of *lucus a non lucendo*, and that it is his duty to keep his eyes shut instead of opening them. He is employed apparently to keep things quiet between the Guardians and the Board at Whitehall; and as long as the sick paupers are quiet, and the officials submissive, he imagines that everything is serene, and that his duty is accomplished by telling his superiors that things are "all right." Deficiency or obliquity of vision seems to be a positive qualification for the office, but a great achievement is effected if he can pull up some Medical Officer for omitting a few entries in a case-book, while the egregious abuses are altogether unnoticed if not purposely withheld from view. We ask again what is the use of the Poor-law Inspectors or of the Poor-law Board

itself if they fail to perform the very duties for which they were appointed?

THE ELECTION OF COUNCILLORS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THIS event, which is now annually looked forward to as one of the medical sensations of the summer season, will come off to-morrow; but we cannot affirm with truth that there is very much on the present occasion either to alarm those who wish to perpetuate ancient abuses, or to stimulate the zeal of those who are the ardent advocates of reform. However, the only point at issue is whether the election shall be a reality, and shall result in the displacement of old elements of the Council, or whether it shall be a mere unmeaning ceremony, concluding with leaving things as they are. It may with all honesty be stated that personal feelings can have very little part in the forthcoming proceedings, for even if, as is contemplated, one member of the present Council should be removed, and one of the senior Fellows elected in his place, there will be very little reason for condolence on the one hand, or of exultation on the other. Mr. LUKE, the member of the Council who will probably be displaced, is a most estimable member of the profession, who has long and honourably served the College in various capacities, and will under any circumstances retain his seat at the Board of Examiners; and Mr. CHARLES HAWKINS, who will probably succeed to his place as Councillor, is well known as a most amiable and excellent man, as well as an accomplished Surgeon. We may mention, *en passant*, that Mr. CHARLES HAWKINS is not a relative of Mr. CÆSAR HAWKINS or Dr. FRANCIS HAWKINS, but he was the intimate friend of Sir BENJAMIN BRODIE.

THE STATE OF THE DRUG TRADE.

ACCORDING to the original *Charter Erectionis* of the Royal College of Physicians of Edinburgh, they were endowed with the power of inspecting all the drugs contained in apothecaries' shops, and destroying all such as were found inefficient, as well as—along with the fraternity of apothecaries—with the sole power of examining and licensing those who desired to open shops for the sale of drugs. All that, however, has been long a dead letter, and, with the advent of free trade, has passed wholly into desuetude; and yet the revelations in the *Lancet* of late years have shown us that in the wholesale drug trade adulterations are or have been extensively practised, and daily experience proves that many retail druggists are not so careful as they ought as to the quality and proper admixture of their drugs. Inspection may be a dead letter, but it is no less—indeed far more—required now than formerly. Not only are many of the drugs now employed far more powerful than those formerly in use, but experience has also taught us that when properly selected for smaller doses are efficacious than was formerly thought possible. Our forefathers would have laughed to scorn the idea of one-sixteenth of a grain of aloes or one-eighth of a grain of rhubarb proving an efficient purgative, or of one-fourth of a grain

of quinine being effective as a tonic; yet there are patients in whom these doses act effectually, and to whom larger doses are injurious, while one-fiftieth of a grain of arsenic or of strychnine are quite commonly prescribed, with the perfect certainty of in due time attaining by their aid the desired physiological and therapeutical effects of the drugs administered. Such being the state of matters in regard to our knowledge of the actions of carefully-selected remedies, it is excessively annoying to the physician to have purgative pills sent home so carelessly mixed that one-half are inert while the other half act too powerfully, thereby protracting the cure, and often disturbing the whole intent with which they are administered. Extracts—a most useful and powerful class of medicines—are often rendered disagreeable or inert by careless preparation; while even simpler articles are frequently rendered useless by want of care in their manufacture; tonic infusions robbed of half their power by inefficient maceration; and even the aqua acetatis ammonia containing free ammonia, or such a quantity of its carbonate as to require large dilution to make it possible to be swallowed. We are only instancing trifles, but they are trifles which exercise an important influence in the treatment of diseases by pharmaceutical remedies, and which, if not observed and inquired into, may injuriously bias our minds as to the actions of remedies, while, as is too well known, instances of more important and more serious blunders are not far to seek. Now, in the common interests of humanity, and in the special interests of the science of our profession, some means ought to be provided for checking even the least of these faults. It won't do to say that we have our remedy in free trade—that if one shop does not make up prescriptions carefully we can send our patients to another; that may be sufficient security for them, but not for the public. What is wanted is some system of self-government and licensing among the druggists themselves, some permanent Board to take cognizance of all complaints in regard to the dispensing of drugs, from the most serious to the most trifling, and to award the appropriate punishment, while this punishment should vary from a mere reprimand up to a temporary or permanent suspension of the license to deal in drugs, the mere possession of this power of suspending the license imparting a powerful weight to the slightest reprimand. This governing Board ought also, at certain stated times, inspect the official preparations in the various shops, to see if they come up to the standard of purity required by the Pharmacopœia. This inspection would not only act as a check on the retail, but also on the wholesale druggists, who, certain of detection and consequent loss of sale in the case of any impurity being discovered, would take special care to secure the purity of every drug sent out by them. By some such system of inspection and regulation not only would both the public and the profession be benefited, but the science of medicine itself would be advanced. Confident in the purity of the drugs and the careful apportionment of each dose, the physician would tread securely where now he often hesitates, and in time, and with care on his part, the true place and power of each fancied remedy would be more certainly ascertained than now they have any chance of being.

M. WORMS states his conviction to the French Academy of Sciences, that under ordinary circumstances, cholera may be certainly prevented from passing into cholera by means of sulphuric acid, which, he says, he has exclusively used in three successive epidemics.

THE EDINBURGH MEDICAL SCHOOL. SKETCH OF THE TEACHERS.

It has occurred to us that a few notes concerning the men who at present occupy prominent positions in the Edinburgh School of Medicine, might be of some interest, especially to those of our readers, who, separated from the metropolis by a distance of many miles, or tied to their posts by the duties of their profession, may have been prevented from paying a recent visit to the place where they received their first lessons in the theory and practice of the healing art.

We shall at present notice

I. THE SURGICAL SCHOOL.

In this department considerable changes have taken place during the last few years. The familiar forms and faces of some who used to be well known, and are still well remembered, as skilful surgeons, brilliant lecturers, and faithful friends, have disappeared from the scenes of their labours and triumphs; and a host of new but rising men has sprung up, men who are destined, we doubt not, to shed additional lustre on our already famous School of Surgery.

The distinguished Professor of Clinical Surgery, still fresh and vigorous as of yore, continues to attract large numbers to his lectures and operations, and a stranger, in dropping in to the amphitheatre, cannot fail to be astonished at the elasticity of step, the quickness of eye, and the steadiness of hand, which still characterise the greatest of living surgeons. Time has indeed dealt very kindly with Mr. SYME, and that he may yet be long spared to adorn by his talents the school in which he first won the spurs of his world-wide fame, is the hearty wish of all his old pupils and friends.

His operations are still marked by the same boldness, precision, and dexterity which long ago called forth the admiration of the profession; and there still exists that wonderfully perfect organisation amongst all his assistants and attendants which, we venture to say, can nowhere else be seen. There is never any fuss, or talk, or confusion, when Mr. SYME is operating, and some of his colleagues might take a leaf out of his book in this respect with advantage. This admirable order and discipline amongst his subordinates is quite in keeping with the calm self-possession and quiet deportment of the operator, and forms a striking contrast to the bluster and flurry which are too common in many operating theatres.

Mr. SPENCE, who is now Senior Surgeon to the Hospital and Professor of Surgery in the University, is generally followed by a very large crowd through the wards; and although not gifted with the oratorical powers of his lamented predecessor, or the neatness of hand of his colleague, Mr. SYME, he is, nevertheless, an excellent surgeon and a most successful operator. Of late his instructions at the bedside have been extremely practical, and as now-a-days the examinations at the various boards are conducted with the view of testing the candidate's knowledge, not only of the theory, but of the actual practice of surgery, these clinical lessons are greatly appreciated by the student.

Dr. J. D. GILLESPIE is at present the Junior Surgeon to the Hospital, and he also holds the office of Lecturer on Clinical Surgery, under the auspices of the Royal College of Surgeons.

Though not a brilliant lecturer or operator, he is never-

theless a surgeon of considerable experience, and is very much esteemed.

Dr. PATRICK HERON WATSON, son-in-law of the late Professor MILLER, is also on the Surgical Staff of the Infirmary, and although quite a young man, and of not more than thirteen years' standing, he has already made for himself a name in the surgical world. He is undoubtedly one of the best operators amongst our surgeons here, and his "style" is much admired. He is possessed, indeed, of most of those qualities which all great surgeons must have; and had his time been entirely devoted to this department instead of being occupied with the duties of general practice, he would undoubtedly have attained to a very high position.

The post of Assistant-Surgeon in Professor SYME'S Clinical wards is held by Dr. JOSEPH BELL, son of Mr. BENJAMIN BELL, a well-known man in the profession. This office of assistant in the clinical wards is of recent creation, and will, we believe, be continued only during Mr. SYME'S lifetime. Dr. JOSEPH BELL is a young man of promise, and several times during the absence of the professor he has discharged all the duties of the clinical chair with much credit to himself and with great acceptance to the students.

Mr. ANNANDALE, a notice of whose recent work on "Minor Surgery" appeared in our last number, is Assistant Surgeon to the Hospital, and also a lecturer on surgery in the extra-academical school. He is devoting his whole attention to surgery, and the opportunities he enjoys as private assistant to Mr. SYME, of becoming acquainted with this department, are very extensive. As yet he has not had very many opportunities of displaying those operative talents of which we believe him to be possessed in public, but his experience for his years is very great, and we hope to see him one day in a position of eminence in the metropolis.

Such is a brief sketch of the men who figure most prominently at the present time in connexion with the Edinburgh School of Surgery. In a future article we shall give a short account of the physicians who occupy appointments in the University, the College of Surgeons, and the Royal Infirmary.

ACTIONS AGAINST MEDICAL MEN.

THE following letter has lately appeared in the *Times*. It may be by an accidental coincidence, but the circumstance is, nevertheless, curious, that Mr. Lewis of Great Marlborough-street has been actively engaged as solicitor in several actions lately brought against medical men. It has been proposed, we believe, that there should be a Defence Fund for medical men who happen to have such proceedings levelled against them; and although we do not advocate any such fund, it may be a fair subject of inquiry whether there exists a "Prosecution Fund" against medical men, or whether those who bring such actions are actuated to do so by mere principles of philanthropy:—

"PERIONOWSKI v. FREEMAN AND ANOTHER."

TO THE EDITOR OF THE TIMES.

SIR,—As solicitor to St. George's Hospital, I have been directed by the Weekly Board of Governors to forward you a communication with reference to the above case, which was lately tried at Westminster before Lord Chief Justice Cockburn.

The claim of the plaintiff for compensation as originally (in July, 1865), submitted to the Governors of St. George's Hospital, and as subsequently presented to the jury, pro-

ceeded upon the allegation that he was forcibly immersed in a hot bath, and was so scalded; but the evidence adduced on the trial clearly showed that the plaintiff was not immersed in a bath, but placed over hot water.

With reference to the observations of the defendants' counsel (Mr. Coleridge) "that the hospital ought to be ashamed of themselves for having allowed such an action to be brought against his clients, and for having refused to compensate the plaintiff," I beg to say that when the claim for compensation was first submitted to the governors, they were perfectly willing to entertain the question, and to give the plaintiff compensation, if satisfied that his claim was an honest one. With that view the matter was referred to me for investigation, and the result of the inquiries which I made in July, 1865, led to the conclusion that the plaintiff's injuries arose probably as much from want of proper caution on his own part as from carelessness on the part of the nurses. This view of the case is borne out by the plaintiff's statement that when the water was poured into the vessel it appeared too hot, in consequence of which, he alleges, he objected to sit over it until forcibly immersed by the nurses.

As to the latter allegation, the Lord Chief Justice, in his summing up, observed, "I cannot help thinking the jury will be of opinion that he was not and could not be telling the truth in that;" and he subsequently added, "I cannot leave the case without observing that a great deal of discredit attaches to the representations of the plaintiff."

Upon investigating the case, I laboured under some disadvantage in ascertaining the real facts, as the under-nurse, who was probably the person best able to give an account of the matter had left the hospital, and could not be found.

Mr. Lewis of Great Marlborough street (the plaintiff's attorney), having addressed two urgent letters to the Governors of St. George's Hospital, and in the latter one, dated July 21, 1865, having asked for the name of the attorney of the hospital, I on that day saw him, and pointed out that the facts appeared to be in many respects incorrectly stated in his letter of complaint, but that the governors regretted his client had sustained an injury while an inmate of their hospital, and were disposed to award him reasonable compensation if the claim was not pressed adversely as a matter of right. Mr. Lewis replied that his client insisted upon compensation as a matter of legal right, and, in answer to my inquiry, he refused to allow the medical officers of the hospital to see the plaintiff, adding that evidence as to his condition would be forthcoming at the proper time.

No further communication with Mr. Lewis took place, and on the 9th of August the writ was issued against the defendants, Messrs. Freeman and Holmes—two of the medical officers.

The governors, as trustees of the funds of a public charity, felt that a claim of such a nature as that set up by the plaintiff should be fairly investigated, and, upon the plaintiff's action against Messrs. Freeman and Holmes being proceeded with, it was determined that the same should be defended at the expense of the hospital.

I attended court for four days for the purpose of giving evidence as to the efforts I had made to arrange the matter, on the footing of the plaintiff being compensated. The head nurse also attended for the purpose of giving her account of the original transaction; but Mr. Coleridge (who was well aware that the action was defended solely at the expense of the hospital), in the exercise of his discretion on behalf of the defendants on the record, abstained from calling the nurse and myself as witnesses.—I am, sir, your obedient servant,

GEORGE F. ELAND.

THE MORISON LECTURES.

THE fifth lecture of this annual series was delivered by Dr. SELLER in the Physicians' Hall, Edinburgh, on the afternoon of Tuesday, the 19th instant. The subject, "Lucid Intervals," was handled in a most interesting manner by the lecturer, who pointed out, by quotations from the classics, how the idea had arisen in past ages, and related from his own recollection how it had till recent times been kept up, by the periodical attacks of lunatics at large in our towns and villages, who, except at these times, were never heard of. He concluded by illustrating the periodicity of insanity by a reference to the periodicity

of disease generally, as based upon the periodical character of all (or at least most of) the phenomena of vitality.

On Thursday, the 21st of June, these lectures were concluded by a most interesting account of Paresis, or General Paralysis of the Insane, as it is usually termed. The lecturer pointed out the differences between this condition and paralysis occurring in the course of insanity, and adopting ROKITANSKY'S pathology that it consists of an increase of the connective tissue elements in the grey matter with a corresponding diminution of the true cineritious corpuscles or cells (chronic inflammation?) showed that though the development of its symptoms might possibly be checked, a cure was never to be looked for, and could not be expected. The lecturer then concluded with a wholly uncalled-for lamentation of his own deficiencies, and explained that the object of Sir ALEXANDER MORISON in founding these lectures was to keep alive in the general medical public—in contradistinction to those usually charged with the care of the insane—an interest in morbid mental phenomena, so that possibly from various sources light might be brought to bear upon them, and thus assist in unravelling their pathology and improving their treatment—an idea truly worthy of their distinguished founder, well adapted for attaining the desired object, and for which a better expositor could scarcely be found than the present lecturer, whose mind is at once matured by large experience and filled with varied learning.

THE EDINBURGH MUSEUM OF SCIENCE AND ART AND NATURAL HISTORY.

PROFESSORS ARCHER and ALLMAN, in a report which has just been issued, give some interesting information in regard to the present position and progress of these two museums.

Now that the collections of industrial art and natural history have been removed into their new and magnificent quarters in the Industrial Museum, the facilities for the exhibition and study of the numerous specimens, which in the course of time have been accumulated, are very much increased, and the interest of the public in such collections is abundantly manifest from the large number of visitors who have flocked to the museums. Some idea of the immense amount of labour which must have been expended on the removal of the collection from its former habitat to its new quarters, and its subsequent arrangement and classification, may be gathered from the fact, that up to the present time somewhere about 4000 specimens have been registered, labelled, and put into their proper place.

The natural history collection has as yet, owing to the delay which has occurred in procuring the necessary cases and fittings, been only partially arranged.

Ere long, however, under the combined and enthusiastic exertions of Professors ALLMAN and ARCHER, this magnificent temple of science and art, will, we trust, be completed, and the student will then have at his command a collection which for variety, rarity, and extent, can nowhere be excelled.

M. POGGIALE tells the French Academy of Sciences that electricity, in his opinion, has a direct influence in developing the physical and intellectual qualities. In one month, by electric baths, &c., he added three centimetres to the height of a youth who was a "positive abortion, intellectually and physically," and raised him from the bottom to the top of his class.

RECENT INVENTION.

A PELVIC UTERINE SUPPORT.

THERE is no disease in women more common, or productive of more serious inconvenience, than prolapsus uteri, and when accompanied, or in a measure caused, as it not unfrequently is, by rupture of the perineum, it is incapable of even being attempted to be remedied without premising a troublesome and not always successful operation. All ordinary forms of pessaries or uterine supports are injurious, in that they are apt to give rise to leucorrhœa, with or without excoriation, while by their very presence, and the mode in which they act, they tend to dilate and relax the vagina, thus ultimately increasing what they were meant to cure; even the very best of the old forms, such as SIMPSON'S wire pessary, were apt to produce discomfort by pressure on the front of the pubis, and were otherwise incapable of affording that firm support which is supplied by that to which to we are about to call attention. This *pelvic uterine support*, as it may be termed—the invention of Dr. CHARLES BELL of Edinburgh—consists in a steel band, an inch broad, covered with leather, which encircles the pelvis, and has a heart-shaped plate of the same material, corresponding to the mons veneris. To a socket in this plate a firm piece of German-silver wire, about nine inches in length, is attached, by means of a screw nail, so as to permit of its being lengthened or shortened, according to circumstances. This wire, while of sufficient strength to give firm support to the womb, is yet pliable, so that it can be easily bent so as to place its uterine extremity in the superior axis of the pelvis; upon this extremity is fixed the pessary proper which may be either a ball or a cup, and upon this the uterus rests. Once properly adapted to the pelvis this support gives not the slightest uneasiness, nor does it in any manner interfere with the true performance of the functions of the pelvic organs. The patient herself takes it out every night, and replaces it in the morning, after it has been properly cleaned, while its continued presence not only does not increase the relaxation of the vagina, but does not even interfere with the application of other remedies calculated to restore its tone, and thus promote the natural cure of that malposition of the womb, the discomforts of which it is the object of this instrument to remedy. As one instance of the pleasing results attained by the use of this pelvic uterine support we may adduce the case of a poor woman, whose perineum had been completely ruptured twenty-five years ago, and who all that time had gone about as best she could, with her uterus supported by a bandage and hanging between her legs. She had been often advised to submit to an operation, but had as often objected. Since being fitted with this instrument some few months ago she carries her uterus in its proper position, and is not only able to go about her household duties comfortably, but can walk any distance without the slightest feeling of uneasiness.

EDINBURGH UNIVERSITY ATHLETIC CLUB GAMES.

THE first annual public competition of this flourishing club took place in Greenhill Park, Morningside, on Wednesday last. The weather was fortunately very fine, although a little too hot, and a very large and brilliant company of ladies and gentlemen assembled to witness the games. We were specially pleased to observe so many professors and

distinguished members of the medical profession present, thus expressing their approval of and interest in such sports.

The various competitions were keenly contested, and it was apparent from the appearance of most of the athletes that a considerable amount of careful training had been gone through.

The vaulting with the long pole and the high leaping were most excellent, and we cannot allow this opportunity to pass without saying a word in commendation of the splendid way in which Mr. J. W. MOIR, son of the late distinguished Dr. MOIR (Delta) acquitted himself. The ease and grace with which he succeeded in clearing a bar five feet seven inches in height, called forth the admiration of all the spectators. Numerous prizes were given, and these were presented to the successful candidates at the close of the day, by the president of the club, the Hon. Lord NEAVES.

We hope that the success which has attended this the first public meeting of the club may stimulate its members to still greater proficiency in those exercises which beautify and invigorate the body.

Correspondence.

POOR-LAW MEDICAL REFORM ASSOCIATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It would be prudery on my part to pretend ignorance of the honour intended to be paid me on July 5th, and, therefore, permit me space to say I hope the meeting will not be confined to the donors of the Testimonial only, but that all Poor-law Medical Officers, who can spare time, will attend, in order that I may take that opportunity of personally consulting them as to the steps they desire to pursue in future in regard to Poor-law Medical Reform.—I am, &c.,

RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, 25th June, 1866.

The meeting will be held at the Freemasons' Tavern, Great Queen-street, on Thursday, July 5th, at three o'clock. If any members of Parliament would honour the meeting with their presence they would be enabled to ascertain the feelings of the profession on the subject of the medical relief of the poor.

P.S.—Medical students are respectfully invited to attend the meeting on July 5th.

DISINFECTANTS FOR THE CATTLE PLAGUE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—You have, in my humble opinion, and, I may venture to say, in that of every right-thinking man who has paid any attention to the subject, done well for the public by exposing the one-sided character of the proceedings of the Cattle Plague Commission relative to the choice of disinfectants to be used against the rinderpest. Of all men in the world an inventor and patentee of a disinfecting preparation ought to have been the very last to have been entrusted with the decision as to the disinfectant to be recommended. Dr. Angus Smith has evidently interpreted the nomination made in his favour by the Commission to imply that he was not expected to take heed of any substances except those specified in his own patent. The result is, that no comparative trials of disinfectants on cattle have been made, and that everything but carbolic and sulphurous acids has been systematically ignored. It is as if the inquiry in respect to the best system of heat of ordnance had been entrusted to Sir William Armstrong alone, and he had not thought it worth while in the experiments instituted by him to bring

into play any but his own guns. The undue advantage which was taken by the late Sir William Burnett of his position as Medical Director-General of the Navy, to introduce Burnett's fluid into the public service, and which at the time was so severely and properly animadverted on, was a trifle compared with what has been taking place under the auspices of the Cattle Plague Commission during the last six months.

The labours of the Commission, so far as disinfection is concerned, have apparently been directed to establish the claims of Smith and MacDougall's patent; and much of the lengthy argumentation indulged in by Mr. W. Crookes in relation thereto, will, on close examination, be found to be little else than a *rechauffe* of the writings of Dr. Smith on disinfection, sanitary economy, &c., in Ure's Dictionary and other publications to which he has contributed.—Yours obediently,

M.D.

London, 25th June, 1866.

OUR SALARIES—THE CONSOLIDATED FUND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As Mr. Gladstone assented to pay half our salaries out of the Consolidated Fund, and as his successor will be certain to accede to it, should we not do one of two things—hold a monster meeting at the "Junction," or some other centre; or append our names to a general petition, praying the Chancellor to interfere only with these "unions in which the medical officers have £100 (or more) yearly."

The petition of 800 professional gentlemen would be certain to have the desired effect with such a Minister as Lord Derby; and granted or not, our illustrious taskmasters and most noble rulers—the boards—might in the meantime grant us the minimum as £100, if not for justice or charity, at least for policy and pocket.—Yours faithfully,

A DISPENSARY DOCTOR.

July 1st, 1866.

CHOLERA HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—If we believe that "events cast their shadows before," and that a disturbance of thermometric equilibrium prognosticates atmospheric changes in the aerial currents, why should it be deemed impossible to foretell with tolerable accuracy the approach of diseases, depending to a great extent on causes propagated or produced by those currents in combination with localized miasmatic influences easily recognizable and in most cases preventible? That the efficient causes which produce cholera are of such a nature has been long understood; also the meteorological conditions prevailing when the disease made its appearance in former epidemics have been recognized, and I think it will not be going too far in stating that those conditions were very similar to others by which we have for some time been surrounded; so that, arguing from past experience, it would be well to stand in readiness lest the trumpet-call of duty sounding the alarm should find us unprepared to defend our out-posts, and thus allow this enemy of our race to gain a march upon us. In no disease more than cholera hangs so much importance on its early recognition, and the application of appropriate means at the very outset is in most cases the best part of the cure. I think it becomes us now, before the actual danger has arrived, to deliberate well what is the best course to pursue should an epidemic of cholera make its appearance amongst us. No false considerations of producing alarm should deter us from the consideration of the subject, especially in the case of cholera—a disease, which if we place any reliance on past experience, is eminently at the very outset under the control of remedies, while in a later stage remedies are not only entirely useless, but in many cases even hurtful. But although I strongly advo-

cate the desirability of discussion as to the best means to be adopted on the appearance of the disease, in the pages of a medical journal, I am as strongly opposed to anything of the kind in papers entirely devoted to subjects non-medical. I do not see any good end to be arrived at by putting forth opinions and suggestions of treatment to be adopted, and which can only be efficiently practised by those conversant with the history of the disease and the nature of the remedies they employ, before a public at all times easily led to apprehend danger from the mere thought or mention of it. Should we desire an illustration of the proneness of the public mind to accept the false apprehension of a real disease by continually dwelling upon a supposed one, we need not travel out of our own land nor beyond our own times. A few weeks since, when the cattle plague was first understood to have appeared among the herds in one part of the country, we immediately heard of some twenty other examples scattered through the land. On inspection by those competent to form an opinion, these were at once determined not to have been cases of the disease at all. Nor otherwise would it be in the case of cholera. Let a suspicious case—or one supposed to be suspicious—occur, and the public papers recount it, and it is truly astonishing how the papers will, we know not how, hear of and comment upon facts which we had supposed buried in oblivion; and should these facts be devoid of any foundation in truth, the greater will in general be the importance placed upon it, and the firmer hold will it acquire on the public mind; thus a *panic* is easily produced, which in itself has been recognized as an efficient cause in the propagation of cholera.

Having premised the above, I will proceed to offer a few thoughts on the measures I conceive it would be advisable to adopt should the epidemic break out amongst us. By this means I hope, Sir, with your permission, to elicit in the pages of this journal (which I consider the legitimate place for so doing) the various ideas capable of being put forth upon so vast and important a subject; and I would arrange what I wish to say on the present occasion in the form of the following suggestions:—

1st. That a committee of medical men be formed as a "vigilance" committee, to whom entire control shall be entrusted of the supervision and management of the hospitals set apart for the treatment of the disease, and under whose control shall be placed all details necessary for the due suppression of the epidemic.

2nd. That the entire of the Dublin district be divided into four sub-districts, two north and two south of the Liffey, in each of which a separate hospital shall be devoted exclusively to the reception and treatment of cases of cholera.

3rd. That as regards reception of cases of the disease into hospitals, each sub-district shall supply cases to its own hospital, set apart for that purpose in the most central part of such sub-district, and none of the hospitals shall admit cases occurring out of their sub-district, except it shall happen that the hospital in the sub-district from which the case is sent be full.

4th. That in each of the four sub-districts, twelve (or more according to extent) medical officers be appointed by the committee as "inspectors" of the district, to whom shall be entrusted the sanitary arrangements required for the prevention of the spread of the epidemic in each sub-district.

5th. That the inspectors be required to visit every house, or other dwelling place, within their sub-district at least once every second day, or oftener, as may appear necessary, and cause to be adopted such sanitary measures as to them shall seem fit.

6th. All persons reported to the committee by the inspec-

tors as affected with premonitory symptoms, however slight, or in a bad state of health, shall be obliged to present themselves before said committee, and should they think fit must submit to detention in hospital.

7th. That each hospital be divided into separate pavilions—*a.* for cases unmistakeably choleraic; *b.* for suspicious cases; *c.* for cases threatened with premonitory symptoms, such as diarrhoea, &c.; *d.* for convalescents; *e.* a department in which all excrements from the sick shall at once be disinfected or otherwise destroyed, so that all noxious emanations shall as far as possible be prevented.

8th. All cases terminating fatally to be interred as soon as possible after death, and such interment to be as private as can be, so as to prevent needless alarm.

If these suggestions should meet with approval, and the necessary steps should be inaugurated to have suitable hospitals, &c., provided, I feel assured that the profession in this city will come forward with many valuable hints on the subject of prevention and treatment of the epidemic, should it unfortunately make its appearance amongst the community. The great advantage, I think, in adopting a method similar to that advocated above, would be the unanimity and promptness of action with which each line of treatment could be put in requisition; the merits of each remedy and the means of preventing the disease would be fairly tested in every case, and these being submitted to one committee, definite rules as to future treatment would be arrived at; and if any remedy exists for the cure of the disease, it would, most likely, by these means be discovered.

Apologising for trespassing so far on your space, believe me, Sir, faithfully yours,

JOHN S. A. CUNNINGHAM, L.K.Q.C.P.I., L.R.C.S.I., &c.
Grosvenor Road East, June 1, 1866.

POOR-LAW MEDICAL STATISTICS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Cogan, M.P., has sent me a House of Commons return for which he lately moved, and which shows the name of each poor-law union in Ireland, the accommodation in each for paupers, the infirmary accommodation in each, the accommodation for fever patients in each, the number of medical officers in attendance on each workhouse or in the infirmary or fever hospital or fever wards of each workhouse, and the salary paid to each medical officer. I copy the enclosed summary of this return, which I hope you may consider a fit one for publication in your journal, as no published official document contains the same information, particularly as regards the medical officers' salaries. It appears that these salaries range from £30 for attendance on some, generally houses of small accommodation, to a more liberal remuneration in those of a larger accommodation. In Belfast, for instance, the three medical officers' salaries is £325; in Cork three receive £300; in the South Dublin house three get £300. The salary of each of the 117 medical officers averages £71 11s. In Ulster the average is £64; in Munster, £83 9s.; in Leinster, £75 5s.; and in Connaught £73.—Your obedient servant,
DENIS PHELAN.
23rd June, 1866.

"DEAR SIR,—I sent my subscription to the Griffin Testimonial twelve months ago. I am grieved and ashamed so small a sum has been subscribed to the Testimonial. Although a poor man with a large family, I shall be willing to subscribe a further sum of £5 if two hundred other gentlemen will do the same to make up a testimonial worthy the labour Mr. Griffin has bestowed upon the cause which interests us all.—I am, dear sir, yours respectfully,

"RICHARD ROE.

"Eccles, June 25, 1866.
"Dr. Fowler."

THE CHOLERA.

RIVETED by the war which has broken out on the continent, public attention for the moment has been diverted from the cholera. The progress of the disease in eastern as well as western Europe has, however, during the past month been such as to require narrow attention. The epidemic has broken out in Jassi, Pocktchani, and other towns of Moldo-Wallachian territory. It is to be presumed also that the malady has resumed its activity in the south-western provinces of European Russia, as active measures against it have been already adopted in St. Petersburg.

In Holland the disease is widely prevalent. From its first appearance in May (?) to the 13th of June 724 cases and 431 deaths had been reported in Leyden; 216 cases and 135 deaths in St. Gravenhage; 396 cases and 220 deaths in Delft; 708 cases and 433 deaths in Rotterdam; 100 cases and 50 deaths in Gouda; and 305 cases and 169 deaths in Utrecht.

In Prussia cholera has declared itself in Stettin, Berlin, Swinemunde, Frankfort-on-the-Oder, Neustadt, Eberwald, Cammin, Arnswalde, and several villages. From the 2nd to the 9th June there were 103 fatal cases in Stettin. Sixty-five cases occurred in two days at Arnswalde. The disease has not yet shown much activity in Berlin and the vicinity—the cases, indeed, would appear to have been scattered mainly in the suburbs.

The epidemic still lingers in the neighbourhood of Altenburgh (Saxony), and it is reported to have shown itself at Chemnitz and near Echernach, on the Rhine.

The need of watchfulness at Liverpool is taught by what has befallen Antwerp. A short time ago cholera broke out on board an emigrant ship, the *Agnes*, in Antwerp port. The disease has now appeared in the city, and to the 16th June there had been 84 deaths and

180 cases, irrespective of those which had taken place among the emigrants on board the *Agnes*.

In France the epidemic has broken out in several places, and it was recently prevailing with great intensity at Amiens. Cholera still shows itself from time to time among emigrant ships sailing from Liverpool to the United States.

The latest news from the East, while confirming the information of cholera having appeared among the returning Mohammedan pilgrims at Jedda leads to the conclusion that the previous reports of the number of cases there were exaggerated. One of the caravans on the route to Medina is, however, believed to have suffered severely. The pilgrims who had reached and traversed Lower Egypt were said to be entirely free from the disease.—*Lancet*.

PROPOSED AMENDMENT OF THE SANITARY LAWS.

A BILL with the above object has been introduced into Parliament by the government. It proposes to enact that there shall be "sewer authority" in districts, which may among other things require the owner of any dwelling house having insufficient drainage to amend deficiency, and to supply water to the inhabitants of such district in the same manner as the present local boards have the power of doing. When complaint is made to any justice, that a sewer authority has made default in these respects, and that a proper supply can be obtained at a reasonable cost, the sewer authority may be summoned before the justice unless they undertake to remedy the fault, and pay the expenses of the complainant. The justice has power to appoint a person to report at a subsequent session as to whether the sewer authority has done its duty according to its promise, and if it has not, to appoint a party to do the work, the sewer authority paying the necessary expenses. With regard to the removal of nuisances, it is proposed that an officer of police may do any act, or institute any proceeding which the nuisance authority of such place might do or execute with respect to the removal of nuisances, and any expenses incurred by him or under his orders in such cases shall be deemed to be expenses incurred in respect of the police, subject to his orders, and defrayed accordingly. The word "nuisance" is to mean any house or part of a house so over-crowded as to be dangerous to health; any factory or workshop not under the operation of any general act for the regulation of factories and bake-houses, not kept cleanly; or properly ventilated; and any fireplace or furnace which does not consume its own smoke. Complaints may be made to the justices of any neglect of duty on the part of the nuisance authority who, on the case being proved, is empowered to make an abatement of the nuisance, at the cost of the nuisance authority. Powers are sought for to cause premises to be cleansed, lime-washed, &c.; to provide carriages for the conveyance of infected persons; of mortuaries for the reception of dead bodies, at the public expense; and to place ships in harbour under inspection, like ordinary dwellings. The Secretary of State, on application of nuisance authority, may empower them to make regulations as to lodging-houses—viz., for fixing the number of lodgings, which may be separately let, or occupied in any house let in separate lodgings within the district, and the number of persons in such lodgings, for the registration of such houses, for the inspection of such houses, and keeping the same in a clean and wholesome state, for enforcing proper means for cleanliness, ventilation of the passages, and lime-washing at stated times, the enforcement of such regulations to be provided for by a fine not exceeding forty shillings for any one offence. Authority is also given to provide either permanent hospitals or temporary places for the reception of the sick. The sewer or nuisance authority may either build such places or make contracts for the use of any existing hospital or part of an hospital for temporary use, but where the nuisance authority is a Board of Guardians the sanction of the Poor-law Board must be obtained to any exercise of the powers given by this section. Penalties are sought to be imposed on any infected person exposing themselves in public, and on persons damaging any works in connexion with refuse or water. Guardians are to execute the Diseases Prevention Act, and they are empowered in certain cases to build baths and washhouses. There are also certain other enactments, which are of a minor character and need not be referred to.

TREATMENT OF CATTLE PLAGUE BY INJECTION OF ARTIFICIAL CHYLE.

Dr. RICHARDSON has forwarded to the Government of Ireland his proposition, made in January last to the Home Secretary, Sir George Grey, for the treatment of animals suffering from cattle plague. This proposition has already been before the profession for several months, but has scarcely received the attention we should have expected. We may, therefore, place in the hands of our readers the following facts, taken from the correspondence between the author of the proposed method, the Home Secretary, and the Royal Commissioners. In his first letter, which was addressed to Sir George Grey, and was forwarded on the 16th of January last, Dr. Richardson writes to ask if her Majesty's Government would allow him for experiment a hundred head of cattle suffering from the rinderpest at various stages of the disease, together with the means of subjecting the animals to treatment. For his purpose he should simply require accommodation in a healthy shed or stable for five or six animals at one time, with proper food for the animals, medicines, two keepers, and a reporter of cases. The only further favour he asks is that two or three scientific commissioners should be deputed to watch the results of the treatment, and to certify to the correctness of those results on his report. He adds that previous to taking this step he had placed all the details of his proposed inquiry before the President of the Royal College of Physicians, and the President, after carefully considering these details, had expressed his opinion that the proposal altogether was based on sound scientific principles, and was of a nature to deserve earnest consideration. This letter led to the placing of the proposition before the Royal Commissioners who were then sitting. The proposition was accompanied with explanatory notes, certain of which we subjoin.

In the first place, as to the curability of the disease, Dr. Richardson offered the following arguments:—

“I premise that the disease is curable, and for the following reasons:—

“1. According to my observation it is a disease affecting one set of organs only—the organs of vegetative life. The secondary changes which occur appear to me to be due altogether to a modified oxidation of the blood. In so far as I can gather, derangement of the nervous centres is no essential part of the malady. I look on these facts as tending to simplify very much every suggestion in respect to treatment, and as affording hope of the discovery of a means of cure.

“2. I observe that there are many instances of a spontaneous recovery in affected animals—a fact which I think especially favours—nay, indeed, proves the possibility of cure. Three days ago I saw two animals, of the same breed and age, in the same stall, fed on the same kind of food, breathing the same kind of air, and suffering from the malady in the same stage and in the same degree of severity. To-day I find that one of these animals died seven hours after I saw it, while the second animal—both having been treated alike—began, soon after the first died, to recover, and did recover so rapidly that it is now comparatively well. If the disease were incurable, why did not both these animals die? It is plain that there is a period during which the malady may be said naturally to last, and that the mode in which that period shall end turns on the power of the animal to pass through the said period. If, while its force is largely expended in eliminating from its body the morbid products that are common to the malady, the animal can also produce sufficient force to sustain a low form of life, it will begin to recover so soon as the elimination of diseased product is perfected. If it fail to produce sufficient force to sustain both elimination and the power necessary to keep the heart and the chest muscles in action, it will die. In plain words, the natural cure of the disease is elimination; and whether the cure be effective or not turns on the ability of the animal to sustain the eliminative process and its own natural processes at one and the same time. I hold, then, that art should step in and should do so little, and yet so much, as should place all animals on a par in respect to their power of sustaining natural recovery.

“The means I would suggest for the scientific treatment of the cattle plague are based on the principles I have laid down in the preceding paragraphs. There are, in my opinion, two clear lines of treatment open, applicable to two special periods of the malady. In the first stage, while the force of

the animal has been but little interfered with or reduced, it would be advisable, I think, to increase the process of elimination and to secure as rapidly as possible the removal of the poison from the organism. In the second and later stages, it would be correct to sustain the animal force so that time might be gained for the perfection of the process of elimination.

“I believe it is possible to carry out both these intentions by means that are rational in principle and easy in application.”

Having described a method of securing elimination by subcutaneous injection, Dr. Richardson continues:—

“To carry out the second intention of treatment, I suggest the artificial feeding of the animals during the later stages of the malady, so as to enable them to live on through the period of natural elimination of the poison. As the disorder presents itself to my mind, the circumstance of recovery turns in every case on the sustainment of secreting force by the animal; while the sustainment of secreting force, in its turn, depends on the power of the animal to take in and apply the source or store of force—food and drink. The common experience is to the effect that if the animals can be fed they live; if they refuse food, or if taking food it remains undigested in the first stomach, they die. In plain words, the blood not being supplied with new force burns out, and as is common in all this class of epidemic disorders, there is thus produced a condition which I have elsewhere designated as asphyxia commencing in the blood; the blood is not oxidised, the animal fire declines, and death—inertia—is the result. How, then, can this condition be met? In the first place, it can largely be met by paying great attention to the feeding and nursing of the animals. If the animals are placed in a warm room, and if they are steadily and persistently fed with food warmed to 90° Fahr., finely cut up, and well softened and diluted with water, the chance of recovery is unquestionably increased. Evidence of a very satisfactory nature on this point admits of being collected.

“But there are many cases in which, though food be introduced into the alimentary system of the animal, it undergoes there no proper digestion nor absorption, the surface of the alimentary canal being itself unnatural and unable to perform its ordinary functions. In these cases feeding by the mouth is of little service. Here I think art ought to step in and render important aid.

“I propose that in these instances the animal should be fed *artificially through the veins*, with a fluid resembling that which it manufactures in its own digestive organs, and throws into its own veins, I mean *an artificial chyle*.

“That an animal can be fed through the veins is a fact proved by experiment. I have fed a dog with blood through the jugular vein for many days together, and into a young dog, that was feeding ordinarily on milk, I have successfully injected milk in the place of blood. Dr. Bovell of Toronto, in 1854, injected milk even into the veins of men in the last stage of cholera, and with very satisfactory results. We might, therefore, safely inject either blood or milk into the veins of cattle in the later stages of rinderpest with promise of advantage.

“There would, however, at all times stand in the way the practical difficulty of obtaining blood or milk on a sufficiently extensive scale. My plan, therefore, is to substitute for the fluids an artificial chyle made by subjecting the ordinary food of cattle to artificial digestion out of the body.

“I have produced a fluid for this purpose so closely analogous to natural chyle that it would be difficult to distinguish it from the natural fluid by common observation. This artificial chyle has a specific gravity of 1030, a dirty-white colour, and an albuminous consistency; it contains albumen and solid matters to the extent of 8 per cent.

“This fluid, warmed to 90° Fahr., I propose to use as food for animals in the later stages of the disease, by injecting it into the external jugular vein in the neck.

“The operation of injection would be as simple as that of ordinary blood-letting. It would merely be necessary to insert a bougie into, and tie it firmly in, the vein, securing the vein above by a firm ligature. The feeding tube in the vein, if provided with a stopcock, need not be removed for many hours, so that several supplies of food might be introduced by the same channel. In introducing the food, it would be best not to use a syringe, but to place the liquid in a gallon barrel, provided with a quarter-inch tap. A tube of india-rubber should pass from the tap to the bougie in the vein, the tube being filled first so as to exclude the air. Then

the fluid being allowed to flow, an elevation of two feet above the animal would give sufficient pressure of current to feed the vein."

The Secretary of the Commissioners acknowledged the receipt of these suggestions on February 8, and intimated that they had been placed in the hands of Dr. Bence Jones, as chairman of the experimental committee.

How far the experiment of artificial feeding through the veins would have succeeded we cannot of course say, though we regret that so simple a means was not tried, and we would urge the Irish Government to test the matter fairly and faithfully. We need scarcely add that Dr. Richardson's plan anticipates by many months the suggested curative measures, by transfusion, which have appeared in the *Times* and other papers during the past month.—*Lancet*.

THE EDUCATION OF MIDWIVES.

THE second annual meeting of the Female Medical Society was held on Monday last at the Hanover-square Rooms, the Earl of Shaftesbury presiding. Dr. Edmunds read the report. It stated that the objects of the Society were but recently looked upon with little respect or sympathy, but a great and increasing change was now perceptible in this respect. Those objects were—(1) to promote the employment of educated women in the practice of midwifery and the treatment of the diseases of women and children; (2) to provide for women facilities for learning midwifery &c., like those which have long been in the possession of men; and (3) to establish a publicly recognized board of examiners, so that women who have pursued an appropriate course of study and passed an adequate examination may be distinguished from others. The progress of the Society's College, at 4, Fitzroy-square, has been thoroughly satisfactory; the number of students has increased to twenty; the lectureships have hitherto proved almost self-supporting, and the entries of students for the next session are likely to exceed in number those of either of the former years. Several students have already mencei practice, and a considerable number of lady patients have been referred to their care. The addresses of accoucheuses who are now settling in various parts of London may be obtained on application at the office, and there is no doubt whatever that this profession will prove a comparatively easy and lucrative employment for intelligent, gentle-handed, and properly educated women, and one to which the public will extend a rapidly increasing patronage. The receipts of the Society for subscriptions and donations amounted to £365 7s.; and for students' fees, paid, £87 2s. 9d.; unpaid, £14 3s. 9d.; making a total of £466 13s. 7d. The payments for rent &c., lecturers' fees, advertising, printing, interest on loan, &c., amounted to £634 1s. 5d., leaving a balance due to the treasurer of £167 7s. 10d. The adoption of the report was moved by Mr. George Burney, and seconded by Lord Houghton, who said that, as a trustee of the Nightingale Fund, he was glad to see that the Society had prospered, and he would do all he could to help it.

The meeting was addressed by Mr. Burney, Lord Houghton, the Rev. J. Burns, Mr. Elt, Dr. Murphy, the Rev. D. W. Corken, and Mr. Turner.

It was moved by the Rev. Dr. Burns, seconded by Mr. Elt, and unanimously adopted,—“That midwifery, as an important branch of medical practice, constitutes a lucrative profession for which women ought to have proper means of instruction, and in which it is highly desirable that women should be employed.”

It was then moved by Dr. Murphy, seconded by Dr. Farr, and unanimously adopted,—“That no sufficient system of instruction in midwifery and the accessory branches of medical science has hitherto been accessible to women in England; that the present utterly unregulated state of female practitioners in midwifery is repulsive to educated women and degrading to this important vocation; that great public inconvenience and frequent loss of life now occur for want of a properly qualified and sufficiently numerous class of midwives.”

Dr. MURPHY, in the course of his observations, said that he could bear testimony to the fact that those women who had attended the Medical College had proved themselves competent to undertake any duty in which a sound practical knowledge of midwifery was required. The object of the Society was no novelty. The duties of midwifery were formerly discharged by women; and it was a well-known fact that Queen Charlotte, the consort of George III., was always attended by a woman, at the births of her children. It was simply owing to the ignorance and want of skill on the part of the midwives that the members of the medical profession took upon themselves the duties of midwifery.

Dr. FARR said that he was glad to see the old English word “midwife” was not discarded by the Society. The midwife was an Anglo-Saxon institution, descended from the remotest time. The dictionaries told us the word came from “meed” (reward), and “wife,” and implied that the wife was to be paid for her work. That was a very proper thing; the labourer was worthy of her hire, and the practice of midwifery was a very legitimate means of gaining a livelihood. It must, however, be frankly admitted that midwifery remained in a very rude state so long as it continued exclusively in the hands of women—old women—whose superstitions were the laughing-stock of the wits and the bane of mothers. In the last century it was taken in hand by men, and by a series of such practitioners as William Hunter, Denman, Davies, Clarke, Ferguson, and a host of practitioners in the present day, including two gentlemen there present—Prof. Murphy and Dr. Edmunds—it had become a science. As an art, midwifery was probably the most advanced and useful branch of medicine. It was now in a state in which its practice might be taught to well-educated women in England, as it was taught to well-educated women in France. In childbirth two lives were at risk, the mother and the child; and sometimes both were lost, when by judicious art both might be saved. In eighteen years (1847-64) no less than 58,001 English women had died in childbirth—18,897 of metria or puerperal fever, and 39,104 of mishaps of various kinds. Nothing struck him as more deplorable in nature than the death of a young mother; when the husband was expecting a child, he lost a wife. He had a long list of the deaths of wives of miners, labourers, masons, ministers, and other classes in remote districts of Wales; and similar series of such deaths happened in other districts. He believed that a great majority of the women of the country, and many poor women in towns, got no skilled attendance in their lying-in. He should be glad to see well-instructed women taking up this old business of their sex—not in opposition to medical men, but in concert with them. The College required help at first; but if women were successful they would be able to pay for their professional training in an institution which appeared to be well suited to teach the art as well as the science of midwifery, and its indispensable subsidiaries, physiology and hygiene. He believed that the medical profession, however much they might oppose female doctors, would be glad to see educated young midwives take the place in every district of ignorant old women. There were more than a million children born every year in the United Kingdom, and on them the perpetuity of the English race depended. It was important that they should start well in the world, and vitally important that they should not lose their mothers. He hoped to see the day when less than five women died out of a thousand delivered of children.

Lord SHAFTESBURY, in his concluding address, strongly urged the friends of the Society to confine the students specially to the prosecution of midwifery, and not to enter upon too extensive a sphere.

The meeting then passed a resolution pledging itself to use all its influence to promote the objects of the Society, and the proceedings were brought to a close by a vote of thanks to the chairman.

Our Weekly Retrospect of the Medical Journals.

JUNE 30.

THE *British Medical Journal* hopes that at the election for the Council of the College of Surgeons the question of voting by paper will be again mooted; it would be a great boon to the country Fellows who, under the present state of things, cannot take part in the management of their own College. We very much fear that the authorities have too much at stake to run the chance of getting a new charter for the purpose of granting this privilege to the extra metropolitan Fellows; some more radical reform might be introduced into it which would seriously inconvenience the oligarchy, which at present dispose of matters surgical in Lincoln's-inn Field.

From all that is written weekly on the subject we have the satisfaction to find that we know nothing of the nature or treatment of cholera. Statistics on the latter portion of the question cannot be relied on.

The promotion in the Guards is to go on as formerly, unless in the case of future medical officers, who will be subjected to the warrant of 1860. So much has been gained by agitation in medical journals.

Mr. S. Smith has withdrawn his name from the candidature for the Council of the College of Surgeons so as to favour the return of Mr. Hawkins and to prevent any miscarriage from the splitting of votes.

The *Times* is unusually severe on Mr. Farnall, the Poor-law Inspector, for his having tolerated so long the system of treatment of pauper sick in workhouses.

The Prussian military authorities find that the most effectual way of curing itch is to smear the part with a mixture of two parts of liquid storax with one part of sweet oil; the cure is complete in twenty-four hours.

Egyptian medical students occupy six years in medical study.

M. Marey has invented an instrument on the principle of his sphygmograph for registering muscular contraction.

Dr. Ricord is justly indignant that his name has been used for the purpose of vending quack medicines.

The *Medical Times and Gazette* draws attention to the wholesale desecration of St. Giles' and St. Pancras' churchyard by the Midland railway. From the description, it would seem as if very many of the bodies so disturbed have not been long under ground, so that the earth and the atmosphere around are impregnated with the results of organic putrefaction; the railway has been obliged to suspend their operations for the present.

The Female Medical Society has held its second annual festival. The chairman, Lord Shaftesbury, impressed on his hearers the necessity of their confining their operations to the education of midwives. It were well if the objectionable name of the society were changed.

A verdict of manslaughter has been brought against a Leicester bone-setter. He employed the force of from twelve to sixteen men to reduce a dislocated elbow; the great pectoral muscle, the axillary artery, and brachial plexus of nerves were torn through. Death occurred from syncope.

Dr. Muspratt, the eminent chemist, describes the nature of the Harrogate spring, which he found to contain iron in the state of chloride, a most valuable discovery, as in this form it is more easily assimilated into the blood of living animals.

The cholera is still making ravages on the Continent.

Mr. Hutchinson's lecture this week, on fractures, has reference entirely to Colles fracture. He asserts that the displacement is due entirely to the violence and not to unusual action.

The *Lancet* calls attention to the various abuses existing in both the Colleges. It points at the fact, that in Lincoln's-inn Fields, the position of the body who were originally and by law intended to be the servants of the Council are in reality the masters. In the case of the College of Physicians it is urged that greater care should be taken in the selection of names for the Fellowship and

that it would be a wise expedient if the attainment of this honour were confined to those who had passed their thirty-second year, and who had served seven years probation as members.

In their petition against the rating of charitable institutions the governors of St. George's allude to an act of suicide which they have been for some years perpetrating; they have actually been compelled to make use of their capital for the support of the hospital, and have sold out to meet current expenses to the tune of four thousand a year for the last seven years.

The most "important pathological discovery yet made in the cattle plague," is the finding of the poison in the blood of infected animals.

Dr. Wilks records a case of cholera which recovered; some will doubt whether this was a genuine case of cholera.

The greater portion of the English medical journals is this week occupied by the half-yearly index.

THE QUEEN'S UNIVERSITY IN IRELAND, DUBLIN CASTLE.

Examination for the Degrees of M.D. & M.CH.

June 8, 1866.—Morning.

MEDICINE.

EXAMINER.—ROBERT D. LYONS, F. & C. K.Q.C.P.I.

1. State the normal average amount of urea and uric acid excreted per diem by a healthy adult male. If the same individual fall into a pyrexial state what alterations in the excretion of urea and uric acid may be expected?

2. Describe the symptoms of a well-marked case of cerebro-spinal arachnitis, and give your prognosis and treatment.

3. What secondary lesions may be anticipated in typhus fever about the end of the second week? Specify the treatment you would employ if the bronchial system became engaged.

4. Describe the sequence of the phenomena when the intestinal lesion of typhoid fever is latent at the outset, and does not progress, *pari passu*, with the primary pyrexia, and the precautions you would adopt.

5. What diseased states are marked by the occurrence of excessively rapid post-mortem decomposition, and what practical indications for treatment during life are furnished by a knowledge of the pathology of such cases?

6. In a case attended with sudden seizure, how would you diagnose between the possible conditions of uræmic poisoning, the syncope of fatty heart, and cerebral apoplexy, and what would be your treatment in each case?

7. What do you understand by the "tonic treatment" of pneumonia? Suppose a case and prescribe accordingly.

8. What symptoms would lead you to the diagnosis of peritonitis from perforation, and what treatment would you employ?

9. What symptoms and signs indicate the approach of tubercularization of the lung, and what means would you employ to avert this occurrence?

10. In what organs has the condition of embolism been observed, and what are the pathological anatomy, the symptoms, and treatment of this condition?

11. What are the conditions which produce systolic cardiac murmur, and how would you diagnose and treat them?

12. In a case of protracted renal disease, with albuminuria and dropsy, what symptoms would induce you to form a favourable prognosis, and what treatment would you employ to conduce to recovery?

Parliamentary Intelligence.

HOUSE OF COMMONS.—JUNE 26TH.

THE SICK POOR IN WORKHOUSES.

MR. FAWCETT asked the Secretary to the Poor-law Board whether he intended to introduce any measure relative to the sick poor in the metropolitan workhouses.

MR. D. BROMLEY asked the President of the Poor-law Board whether any steps were being taken towards the establishment of some system of supervision of the sick

wards in metropolitan workhouses, whereby the painful circumstances recently disclosed might be prevented from recurring pending the result of Dr. Smith's inquiry, and whether the result of Mr. Farnall's visits and investigations would be laid upon the table.

Mr. VILLIERS, in reply to both questions, said that a very full official and medical inquiry had been directed by the Government to be made into the condition of the infirmaries of these workhouses. That inquiry had been completed, and the report was on the table of the House. The subject was one which required very early consideration.

Abstracts of the Scientific Societies.

ROYAL.—June 14.—The following papers were read: "On the Anatomy of the Fovea Centralis of the Human Retina," by Mr. J. W. Hulke.—"Second Memoir on Plane Stigmatics," by Mr. A. J. Ellis.—"Fundamental Views regarding Mechanics," by Prof. Plücker.—"Contributions to Terrestrial Magnetism, No. 10," by General Sabine.

STATISTICAL.—June 19.—W. Farr, Esq., M.D., in the chair.—The Duke of Argyll read a paper, "On the Economic Condition of the Highlands of Scotland." The following are the facts and conclusions which the noble author arrived at with regard to the past and present economic condition of the Highlands: 1st. That before the end of the last of the civil wars the condition of the population was one of extreme poverty and frequent destitution. 2nd. That on the close of these wars and the establishment of a settled government, there was, during half a century, a rapid increase of population. 3rd. That this increase was out of all proportion to the means of subsistence. 4th. That the introduction of potato cultivation increased the evil of a rapid increase in population without any corresponding increase in skill or industry. 5th. That the emigration of the Highlanders arose as a necessity out of this condition of things, and was in itself the first step towards improvement. 6th. That the introduction of sheep-farming was a pure gain, not tending to diminish the area of tillage where tillage is desirable, and turning to use, for the first time, a large part of the wnooffhole area the untry, which was formerly absolutely waste. 7th. That for the old bad cultivation of small crofters there has been substituted for the most part a middle class of tenantry, thriving, holding under lease, and exhibiting all the conditions of agricultural prosperity. 8th. That the displacement of population by the introduction of great capitalists holding farms of very large value has not taken place in the Highland counties to an extent nearly equal to that in which it has taken place in some of the richest counties of Scotland. 9th. That the process which has been going on in the Highland counties of a diminution in the population of the rural districts is the same process which has, long ago, been accomplished in the other counties of Scotland, and in England. 10th. That in their case it was also deplored under the same economic fallacies—fallacies which are now applied only to the Highlands, because the process is not yet completed. 11th. That the prosperity of the Highlands will only be complete when the process shall have been completed also. 12th. That no part of Scotland, considering the late period at which improvement began, has advanced so rapidly, or given, within an equal space of time, so large and so solid an addition to the general wealth of the country.

ZOOLOGICAL.—June 12.—Dr. J. E. Gray, V.P., in the chair.—A communication was read from Dr. H. Dohrn, "On the Birds of Prince's Island, in the Bight of Zenin, West Africa," being founded on personal observations made during a recent exploration of that island. The species enumerated by Dr. Dohrn, as met with him in that locality were thirty-four in number, amongst which were several new to science.—A communication was read from Mr. J. Couch, giving an account of the occurrence of *Ausonia Cuvieri*, a fish new to the British Fauna, on the coast of Cornwall.—Dr. Gunther contributed some notes on the anatomy of the same fish, which presented several very noticeable peculiarities.—Dr. J. Murie gave an account of a singular case of malformation in the generative organs of a heifer, which had been recently transmitted to the Society by Mr. G. Latimer of Porto Rico.—Dr. Murie also read some supplementary notes on the red-bellied monkey (*Cer-*

copithecus erythrogaster), a new species founded by Dr. Gray upon an animal lately living in the Society's menagerie.—Dr. Gray communicated some notes by Lieut. C. F. F. Annesley, R.A., "On the Habits of the Mantis Crab (*Gonodactylus chiragra*) in Captivity," as observed by that gentleman at Aden.—Mr. A. D. Bartlett made some remarks on the singular bird of prey lately transmitted from Damaraland by Mr. Anderson, and described by Mr. Gurney as *Stringonyx Andersoni*, and suggested its identity with the *Machaerhamphus alcinus*, described some years previously by Mr. Westerman, but stated, probably erroneously, by the latter author to have been received from Malacca.—A joint paper was read by Messrs. A. B. Wallace and F. Moore, "On a Collection of Lepidopterous Insects obtained in Formosa by Mr. Swinhoe."—Mr. H. W. Bates read a paper "On the Coleopterous Insects obtained by Mr. Swinhoe in the same Country."

CHEMICAL.—June 7.—The papers read were:—"On the Oxidation Products of the Propione produced from Carbonic Oxide and Sodium-Ethyl," by Professor J. A. Wanklyn.—"A Preliminary Notice on Phthalic Aldehyde," by Professor H. Kolbe and Mr. G. Wirchex.—"On the Preparation of Chrysammic Acid," by Dr. J. Stenhouse and Dr. H. Müller.—"On Chrysammic Ether," by Dr. J. Stenhouse.—"On the Platinum Bases, the best Mode of obtaining and identifying them," by Mr. E. A. Pladow.—"On some Decompositions of Nitrite of Amyl," by Mr. E. T. Chapman.—"On a Cyanogen Derivative of Marsh Gas," by Mr. H. Basset.—Mr. A. Vernon Harcourt delivered a lecture "On the Observation of the Course of Chemical Change."

ERYTHROXYLON COCA.

Dr. REIS, in the *Bulletin Gén. de Therapeutique*, of Feb. 28, 1866, writes with regard to the Erythroxyton Coca:

"In January, 1863, as some of my colleagues may remember, I published an account of some experiments made with the leaves of the *erythroxyllum peruvianum*, *erythroxyton coca*, a plant which is used by the Indians of Peru as a masticatory, in doses of fifteen to twenty-five grammes daily for the purpose of enabling them to undergo fatigue, hunger, and thirst, or the severe labours of the mines.

"I have subsequently verified the powerful yet inoffensive efficacy of this substance as a nervous stimulant. On the one hand results are augmented, and continued activity of the mental faculties, rendering elocution easy and animated, and inspiring resolution, courage, and perseverance; on the other, an increased disposition to muscular action as shown by facility in locomotion, which can be continued without fatigue for a long period during the mastication of the coca. Hence, my observations have led me to regard this stimulant as an agent well adapted to distract the mind from its habitual cares, and sustain temporarily the vital forces, with or without a moderate use of food. Doses of two, three, or four grammes of coca, renewed at seasonable intervals, are sufficient to produce these physiological effects.

"The experiments of MM. Gorse and Mantegazza have, however, shown that in large doses the Peruvian leaf causes an acceleration in the cardiac contraction four times greater than that produced by tea, more than twice as much as that resulting from coffee, and at least a third greater than that which follows the employment of the *Ilex maté*. When used in doses of thirty to forty grammes, an intense fever, accompanied with hallucinations and delirium follows. Being among the first to call attention to the prompt, energetic, and almost poisonous action of the coca, I cannot but recommend its employment in diseases characterized by marked depression of the nervous and muscular system, and particularly in cholera."

Dr. Reis then goes on to state that he has used it during the recent epidemic, but adds that no severe cases came under his observation. In a few in which aligid symptoms began to make their appearance, and the pulse was small and almost imperceptible, the use of the remedy was followed by apparently good results. It may be administered in the form of elixir, syrup, extract, infusion, masticatory, or may be smoked like tobacco. The experiments made in this country with the coca do not confirm the very sanguine opinions of Dr. Reis. The results have been contradictory. It is, however, a remedy worthy of further examination, since if half which has been told of it were true it would be very valuable in some nervous diseases.

VISITATION OF EXAMINATIONS.

At a meeting of the Branch Council for England of the General Council of Medical Education and Registration on the 15th inst., the following resolution, passed by the General Council on the 28th of May, was read:—"That the visitations of the examinations, preliminary as well as professional, of the qualifying bodies, by the Branch Councils, or such of their members as they may depute, be continued during the ensuing year. That the reports of the visitors shall apply to every part of the examinations of each body, and shall include a statement of the facts observed, and of the opinions of the visitors as to the efficiency of the examinations, as also such remarks and suggestions on defects in them as circumstances may indicate. That the reports of the visitors be submitted in the first instance to the Branch Councils; and that thereafter the Branch Council shall direct them to be printed and circulated confidentially amongst the members of the General Council, so that they be in a condition at the meeting of the General Council in 1867 to consider them maturely." It was also resolved that the members of the Council who were deputed by this Branch Council on the 13th of October, 1865, to visit the examinations held by certain of the qualifying bodies in England, be again deputed to visit respectively the examinations of the same bodies during the ensuing year. Dr. Storrar and Dr. Sharpey were deputed to visit the examinations of the University of Durham. A letter from Mr. Rumsey was read, explaining his reasons for declining to take part in the visitation of examinations. Dr. Alderson was deputed, in place of Mr. Rumsey, to visit the examinations of the Society of Apothecaries of London. It was resolved that the travelling and hotel expenses of members of this Branch Council deputed to visit the examinations of the qualifying bodies, be paid to them on the same scale as for attending the meetings of the General Council; and that the consideration of the question of the payment of fees to the visitors of examinations be, for the present, postponed. A present of fifty guineas was made to the registrar of the English Branch Council, in acknowledgment of the extra duty entailed upon him by the registration of medical students.—*Lancet*.

Notices to Correspondents.

- M.D.*—The letter is inserted.
The Harveian Society of London.—The report has been received.
Dr. Dickson.—The paper has been received.
Dr. B.—It is better to let the matter rest until after the trial.
Mr. Griffin's letter is inserted.
Dr. Paul.—The paper has been received.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows held on June 25th, the following gentlemen, having undergone the necessary examination, were duly admitted Members of the College:—

Charles, T. Edmondston, M.D. Edin., Elizabeth-terrace, Eaton-sq. Congreve, Richard, Southampton-row.
 Cumberbatch, Lawrence Trent, M.D. St. Andrews, Cadogan-place.

At the same meeting, the following College officers were elected for the ensuing year:—Censors: Dr. Guy, Dr. Herbert Davies, Dr. George Johnson, Dr. Peacock. Treasurer: Dr. Alderson. Registrar: Dr. Pitman. Librarian: Dr. Munk. Examiners: (Anatomy and Physiology) Dr. Handfield Jones, Dr. Brinton; (Materia Medica, Chemistry, &c.) Dr. Barclay, Dr. A. S. Taylor; (Principles and Practice of Medicine) Dr. F. J. Farre, Dr. Sieveking; (Midwifery and Diseases peculiar to Women) Dr. West, Dr. Oldham; (Principles and Practice of Surgery) Mr. Holmes Cooté, Mr. G. D. Pollock. Curators of the Museum: Dr. Alderson, Dr. Hamilton Roe, Dr. Wm. Wegg, Dr. Sibson.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on June 21st:—
 Crowther, Edward Lodewyk, Hobart, Tasmania.
 Jackson, Mowbray, Bowbrickhill, Bucks.
 Lamb, Barnabas Walter, Stourport.
 Pryce, Richard Matthews, Caersws, Montgomery.
 Quick, John, Penzance.
 Sanders, Thomas, Plymouth.
 Turner, Duncan, Peter-street Islington.
 Wilcox, Richard Wilson, Torrington-square.

The following gentleman also on the same day passed his first examination:—

Bland, Henry, King's College.

THE SOIREE OF THE ROYAL COLLEGE OF PHYSICIANS.—This annual gathering was held on Wednesday evening last, and was very numerously attended, not only by members of the profession but by visitors of eminence, amongst whom were the Bishop of Oxford, Mr. Tite, M.P.; Mr. Waldegrave Leslie, M.P.; Vice-Chancellor Wood, Sir J. Shaw Lefevre, and Sir J. Key Shuttleworth. The following amongst a host of other models and apparatus were exhibited:—By Professor Wheatstone: Means of communication between carriages on railroads. Professor Abel: Specimens of gun cotton and a lead-coated projectile, exhibiting results produced by electrolytic action. Mr. Ansell: Apparatus for detecting fire-damp in mines by the diffusion of gases. Mr. Herbert McLeod: Oersted's condenser for showing the liquefaction of gases by pressure, and the compressibility of water. Dr. Bence Jones: Animal florescence; Holtz electric machine. Dr. Lionel Beale: Specimens illustrating the mode of termination of the ducts, and other points in the anatomy of the human liver; cirrhosis of the liver; the connexion of the Malpighian bodies with the tubes of the kidney. Dr. J. B. Sanderson: Enlarged copies of tracings obtained by the application of a modification of the sphygmograph in the investigation of the movements of the heart and great vessels. Dr. Hassall: Samples of flour of meat, with several preparations made therewith, as also pure bran or bran and meat biscuits, for diabetes, absolutely free from starch. Dr. Thudichum: Microscopic illustrations of entozoa, including living trichina and tænia echinococcus, shown by means of the oxy-hydrogen and the electric microscope; and tables of new atomic weights. Mr. Jabez Hogg: Microscopic exhibition of lingual bands of cephalopods. Mr. Stear: Collection of wild plants—Essex. Mr. Wheeler: Microscopic objects and specimens. Messrs. Khroné and Sesemann: The instruments of Dr. Richardson for producing local anaesthesia, spray producers, laryngoscopes, &c. Mr. Browning: Micro spectroscopes exhibiting curious spectra, prisms, telescopes, &c. Mr. Collins: Microscopes and the new Webster condenser. Mr. Ladd: Wilde's magneto-electric machine—vibration of cords. Mr. F. Joubert: Photographic pictures on enamel. Mr. T. H. Collins: Photographs (Mayall). Messrs. Powell and Lealand: Binocular microscopes for high powers; circulation in the vallisneria, &c. Messrs. Murray and Heath: Demonstrating class-microscope, and field microscope with folding stand, &c. Parkesine Company: Specimens of Parkesine. Mr. Pulvermacher: New volta-electric flexible batteries.

THE SERIOUS CHARGE AGAINST A BIRMINGHAM SURGEON AND OTHERS.—On Friday, at the police-court, Birmingham, Ellen Elizabeth Owen, 37, herbalist, William Vernon Smith, 54, surgeon, and William Bromfield, 28, clerk, were charged on remand with having conspired and induced a married woman, named Elizabeth Ellesmore to procure abortion. From the evidence given on the last occasion it may be remembered that Bromfield, who had been keeping company with Ellesmore—who had for several months been separated from her husband—took her to the woman Owens in order that some medicine might be given her to procure an abortion. Owen's medicines failed, and Mr. Smith was then resorted to, a premature delivery being followed by a narrow escape of Ellesmore from death. For the defence it was urged, on behalf of Smith, that he knew nothing of the affair beyond being called in to treat the woman for typhoid symptoms. All the prisoners pleaded not guilty, and were committed for trial.

ITALIAN MILITARY SURGEONS.—The army being on a war footing and requiring additional medical officers, hundreds have offered their services, which have been accepted. As to the volunteers, so many surgeons applied for employment that the Director-General, Dr. Bertani, not having room for all, has incorporated the surplus into a special company, which is to accompany the volunteers as a kind of medical reserve.

CHOLERA has again broken out at Guadaloupe; and fever prevails at Barbadoes, but is not of a malignant type.

THE following are the results of the first operations of the sanatorium in Madeira, in connexion with the Brompton Consumption Hospital. Of the twenty male

patients sent out last year eighteen have returned, one being still under treatment in the island. Of the whole twenty, twelve have improved considerably, four others may be considered as stationary, three are not so well as they were six months ago, and one has died.

At their meeting last week the Royal Society elected on their list of Foreign Members Franz Cornelius Donders of Utrecht, Georg Friderich Bernhard Riemann of Göttingen, and Gustav Rose of Berlin.

A HANDSOME gilt time-piece, under a glass shade, was presented last week to Dr. W. K. Robinson, on his retirement from the post of Officer of Health to Birkenhead, which he has held for the last few years.

A CASE of cholera has occurred at Sunderland, in one of the ships. Due precautions have been taken against the disease spreading.

THE cholera has made its appearance in the camp at Chalons.

GARIBALDI has summoned his old friend, Alessandro Gavazzi, to assist in the care of the military hospitals. These two distinguished men have frequently been associated in serving their country in their different vocations. They were together on the walls of Rome when the city was besieged by the French in 1849, and again during the successful campaign of 1860, during which Gavazzi was appointed President of the Commission for the succour of the wounded.

IN London 2136 children were registered during the past week, and the deaths were 1540.

EXTIRPATION OF SCAPULA.—Dr. Hammer of St. Louis, reports in the *New York Medical Journal* for May a case in which he removed the entire left scapula and the acromial end of the clavicle, preserving the arm, in a young lady aged eighteen, for encephaloid cancer. The operation was in September, 1860, and the patient made a good recovery. The disease, however, recurred in the following March, and she died in July, 1861.

ADVICES from the Hague state that Queen Sophia had gone to visit the cholera patients at the hospital of that place, which proceeding produced the best effect on the minds of the people, who were commencing to become alarmed. The epidemic is on the decrease.

AN inquest was held on Saturday last, at Newcastle, upon the body of Mr. William Collins, a surgeon, who died quite suddenly. It was proved that death proceeded from disease of the heart, and the jury returned a verdict accordingly.

ONE of the last Acts passed during the late Administration was to enable boards of guardians in Ireland to provide coffins and shrouds for the burial of poor persons who, at the time of their death, were not in receipt of relief from the poor-rates.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—We have been requested to state that Dr. Grattan Guinness, F.R.C.S.P., of 24, Lower Fitzwilliam-street, having been appointed one of the Hon. Secretaries of the above Society in place of Dr. Churhill, resigned, all communications should in future be addressed to him.

A SCENE IN CALLINGTON MARKET.—On the last market day at the quiet town of Callington an amusing scene occurred. It appears that one of the gentry who vend worm lozenges—worms being of course at the root of all diseases—was expatiating on the virtues of his nostrums, and in relating instances of their curative powers, he mentioned with no small delight a case in which he had been the means of saving the life of a patient of the greatest physician in the West of England, Dr. Budd, who had dismissed the patient as incurable. Unfortunately for the quack, "the greatest Physician in the West of England" was passing near his stall at the time, and hearing his name mentioned was naturally arrested at the sound, and listened. The doctor's temper was roused, and just saying "Let me get at him," then and there administered sundry kicks on the nethermost person of the unfortunate quack,

which had the effect of putting him *hors de combat*. Roars of laughter greeted the onset of the valiant doctor, in the midst of which the vender beat a hasty retreat. The doctor enjoyed the scene as much as the bystanders, and related the circumstance with much gusto many times during the day.—*Western Mercury*.

Medical Diary of the Week.

LONDON—WEDNESDAY, JULY 4.
 ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ a.m.
 MIDDLESEX HOSPITAL.—Operations, 1 p.m.
 ST. MARY'S HOSPITAL.—Operations, 1½ p.m.
 ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ p.m.
 ST. THOMAS'S HOSPITAL.—Operations, 1½ p.m.
 GREAT NORTHERN HOSPITAL.—Operations, 2 p.m.
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 p.m.
 LONDON HOSPITAL.—Operations, 2 p.m.
 OBSTETRICAL SOCIETY OF LONDON.—7 p.m. Meeting of Council.—8 p.m. Dr. Routh, "On a New Mode of Treating Epithelial Cancer of the Cervix Uteri and its Cavity;" Dr. Tilt, "On the Present Surgical Tendency of Uterine Pathologists, and on Division of the Cervix Uteri;" and other papers.

DIETARY AT THE HOMOEOPATHIC HOSPITAL.

Take a robin's leg—mind, the drumstick merely,
 Put it in a tub filled with water nearly,
 Set it out of doors in a place that's shady,
 Let it stand a week—three days if for a lady.
 Drop a spoonful into a five-pail kettle,
 Which should be made of tin, or any baser metal;
 Fill the kettle up—put it on a boiling,
 Strain the liquor well, to prevent it oiling;
 An atom add of salt, for thickening one rice kernel,
 And use to light the fire "The Homeopathic Journal."
 Let the liquor boil—half an hour—no longer,
 (If for a man, of course you'll make it stronger);
 Should you now desire that the soup be flavoured,
 Stir it *once* around with a stalk of savoury,
 When the broth is made, nothing can exceed it;
 Then, three times a day, let the patient smell it;
 If he chance to die—say, 'twas Nature did it;
 If he chance to live—give the soup the credit.—*Public Opinion*.

BIRTHS.

NADIN.—On the 27th June, at Tipperary, the wife of Joshua G. Kooystra Nadin, Esq., Surgeon, of a daughter.
 HAYWARD.—On the 16th ult., at Wintstable, the wife of J. W. Hayward, M.R.C.S.E., of a daughter.
 KINGSFORD.—On the 1st inst., at Upper Clapton, the wife of Dr. Kingsford, of a daughter.
 POWER.—On the 1st inst., at Upper Seymour-street, Portman-square, the wife of H. Power, F.R.C.S.E., of a daughter.
 SMITH.—On the 2nd inst., at Burbage, Wilts, the wife of C. S. Smith, M.R.C.S.E., of a daughter.
 DIVERS.—On the 6th inst., the wife of E. Divers, M.D., of Queen's College, Birmingham, of a son.
 NORTON.—On the 6th inst., at Westbourne-grove, Bayswater, the wife of A. C. W. Norton, M.D., of a daughter.
 DEBENHAM.—On the 7th inst., at Heath House, Stepney, the wife of R. Debenham, M.R.C.S.E., of a son.
 HORN.—On the 16th inst., at Dalton in Furness, the wife of Wm. Horn, surgeon, of a daughter.

MARRIAGES.

SWAN—GODDARD.—On June 26th, at St. Maurice's Church, Winchester, by the Rev. H. Borefield, M.A., Rector, assisted by Rev. Charles Collier, A.M., Principal of Training College, John W. Swan, Esq., M.D., to Henrietta Lucy, second daughter of the late William Goddard, Captain R.N. No cards.
 BLAKE—HANSON.—On June 27th, at Newport, Salop, Edward T. Blake, M.R.C.S., of Wolverhampton, to Annie Madeline, eldest daughter of the late Sidney Hanson, M.D. No cards.

DEATHS.

MACFARLAN.—On the 4th ult., at George-town, Demerara, A. S. Macfarlan, M.D., aged 58.
 GILLHAND.—On the 22nd ult., W. L. Gillhand, M.D., of Hereford.
 HAYNES.—On the 31st ult., R. L. Haynes, F.R.C.S.E., of Haringey-park, Hornsey, aged 57.
 BIRNE.—On the 31st ult., M. Birnie, Surgeon, of Old Aberdeen, aged 80.
 TUNALEY.—On the 5th inst., C. Tunaley, M.R.C.P.L., of Millbrook-place, Harrington-square, aged 58.
 SINCLAIR.—On the 8th inst., at Carsewell House, Holbeton, South Devon, Duncan Francis Sinclair, M.R.C.S.E., L.S.A., aged 24.
 PERKINS.—On the 13th inst., at Avranches, France, Houghton Stephen, of Middlesex Hospital, eldest son of Houghton Perkins, F.R.C.S., of Mortimer-street, aged 27.

THE RINDERPEST OF THE PRESENT TIME, AND THE CATTLE PLAGUES OF PAST AGES, IN THESE ISLANDS, AND ON THE CONTINENT.

By THOMAS MORE MADDEN, M.D., M.R.I.A.,

LICENTIATE OF THE KING'S AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; MEMBER OF THE ROYAL COLLEGE OF SURGEONS, ENGLAND; LICENTIATE OF THE FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW; DEMONSTRATOR OF ANATOMY, CARMICHAEL SCHOOL OF MEDICINE; AUTHOR OF "CHANGE OF CLIMATE IN PURSUIT OF HEALTH," "THE CLIMATE OF MALAGA," "OBSERVATIONS ON INSANITY AND CRIMINAL RESPONSIBILITY," &c., &c.

No I.

ITS SYMPTOMS—NATURE—CAUSES—DIAGNOSIS, PREVENTION AND TREATMENT.

My principal motive for undertaking this inquiry into the epizootics of the past and present time has been a hope to aid in the study of those laws which govern epidemics, and to illustrate the connexion between the epizootics which attack the lower animals and the epidemic pestilences which attack mankind.

The plan adopted in the following essay is, in the first place, to give an account of the existing cattle plague, its nature and treatment; then follows a historical notice of cattle plague in Ireland, down to the present day, succeeded by a sketch of the general history of the diseases analogous to the rinderpest, and the views as to their nature and treatment held in former times; concluding with some observations on the relation between epizootic and epidemic disease.

To no country in Europe is the value of stock so great, in proportion to the value of all agricultural produce, as in Ireland, and to none, therefore, is a question, as the cattle plague, which so deeply affects the existence of this description of property, of more vital importance. In Ireland the estimated average annual value of the crops, as given by Mr. Thom in his "Statistics of Great Britain and Ireland" (p. 70), is but £28,369,176, while the value of live stock amounts to £47,160,507.

The character of the disease now epidemic among cattle in England, has excited much, and sometimes even angry controversy. It has been stated to be identical with typhus and typhoid fever, with small-pox, scarlatina, and other eruptive diseases. Its similarity with typhus fever has been long believed in France, where it is known as *Typhus des Bêtes à cornes*. Last autumn, the French Government sent a commissioner over to England to investigate the cattle plague, and that gentleman's report, which was published in *L'Union Médicale* of August 31st, 1865, states that "the cattle plague is a contagious typhus, brought over from southern Russia and the Steppes of Asia, which are regarded as the birth places of the disease." And in the *MEDICAL PRESS*, December 27th, 1865, I published a translation from the French on this subject, in which the identity of the cattle plague with typhus fever is insisted on. The idea that rinderpest is analogous to typhoid fever is, I think, untenable.

At a meeting of the Pathological Society of London, in October, 1865, Dr. Murchison exhibited several specimens and drawings from healthy and plague-stricken oxen, from which he drew the conclusion founded on the result

of twenty-seven dissections of the latter, that the characteristic lesion of the intestinal glands, pathognomonic of typhoid or enteric fever in man is entirely absent in cattle that die of the cattle plague, and that, therefore, this epizootic is not a similar disease.

The theory that the cattle plague is small-pox—that was put forward last autumn by Drs. Murchison, Watson, &c., which, although the plan of prevention by inoculation to which it gave rise, not proving as successful as was anticipated, was abandoned, yet offered the most rational method of prophylaxis suggested, is but the revival of a theory as old as the sixth century, when the Burgundian Bishop Marius wrote of the cattle plague in the year 570, "Hoc anno morbus validus cum profuvia et variola, Italiam, Galliamque valede affixit, et animalia bubula per loca superscripta maxime interierunt." And in his admirable description of the cattle plague in Italy in 1711, Ramazzini recognised its resemblance to small-pox; he says, "pustulæ quinta vel sexta die per totum corpus eruptentes, ac tubercula variolarum speciem referentia" (*Opera omnia*, p. 788, Geneva, 1716).

In 1786 (as we read in the *Medico-Chirurgical Review* for 1802), Dr. Heirze published an account of the treatment of the cattle murrain, then epidemic in Denmark, by inoculation, which is asserted to have been productive of great benefit to that kingdom.

Many other theories as to the character of the cattle plague have been put forward, but the foregoing are the most important. The only point with respect to which all the authorities on the subject agree, is that the cattle murrain is a low febrile affection of some kind, beyond this they differ, as we have seen, very widely. It has, however, been proved, I think, beyond doubt, that the cattle disease differs from all the maladies with which it has been confounded, and the probability is that it is a separate disease, *sui generis*, and is the same as that prevailing from time immemorial in the Russian Steppes, and there known as the *Rinderpest*. The disease to which it presents most analogy being Irish typhus fever.

From the theories which have been promulgated as to the character of the cattle plague, we now come to examine the facts which have been ascertained on the subject. In the first place, there can be no doubt that the rinderpest is a highly contagious febrile disease, of a low type, chiefly attacking the bovine species. It is eruptive, the eruption consisting of resolar patches, of a scaly character (some writers have observed pustules, but this fact is denied by others) on the skin of the loins and back. This eruption is peculiarly observable on the udder, and may also be clearly seen on the inside of the thighs, as well as the mammary glands. Like other diseases of the same class it only occurs once during life, and the period of incubation is about ten days.

The symptoms which usher in the rinderpest are a dull and spiritless condition of the infected beast, and if this attract attention, on examination there will be found to be a rise of from two to three degrees in the natural temperature of the animal. This fact, the discovery of which is mainly due to Professor Gamgee and Dr. Saunderson, is one of the most important which have been ascertained in connexion with the disease. For practical purposes it affords a simple method of recognizing the earliest stage of the disease by the thermometer, for if the temperature of the suspected beast suddenly rise from the natural standard, 102° to 104° or 105° Fah., it may generally be pronounced, while the rinderpest prevails, to be infected, even in the absence of any other symptom, and while the animal is apparently in ordinary health, this rise of temperature generally occurring from thirty to forty hours after the animal is infected. About two days later, on the second or third day of the disease, an eruption very similar to that of thrush, may be observed on the gums and inside of the lips. This extends along the mucous membrane of the mouth, and by the sixth day this is covered with a white aphthous exudation, interspersed with raw denuded patches of a vivid red colour. Simultaneously

with the first appearance of these symptoms, on the second or third day, the mucous membrane of the vagina in cows presents a peculiar pathognomonic congested appearance, and the secretion of milk diminishes rapidly and soon ceases.

It is not till the fourth day of the illness that the plague-stricken beast shows unmistakable signs of the disease. The head now droops, the ears are drawn back, the coat is rough and staring, the eyes are dull and congested, and there is a discharge from them as well as from the mouth and nostrils. There is shivering alternately with a hot skin; the breathing is short and frequent; the animal moans as if in pain; it refuses food; the circulation fails; the breath is fetid. Generally there is constipation at first, followed, as the disease progresses by diarrhoea and tenesmus. A marked loss of muscular power is now the most remarkable symptom. Should the case, as it will probably end fatally, these symptoms continue to increase; the temperature falls much more rapidly, and more than it first rose, and the animal dies about the seventh day from the accession of the disease.

The pathological lesions most commonly observed after death from rinderpest are, a generally congested appearance of the mucous membranes, which is especially observable in the mouth, pharynx, and œsophagus. The mucous membrane of the mouth is generally a dull red colour, and is frequently covered with aphthous ulcerations. In the first and second stomachs the chief thing to be noticed is a quantity of undigested food; the third stomach, or omasum, is also full of exceedingly dry, hard, and undigested food, and the papillæ are red and enlarged; in the fourth stomach, the reed or abomasum, there is much evidence of inflammation; there occasionally large black patches of ecchymosis, the mucous membrane is extensively denuded of epithelium, and is sometimes even ulcerated. In the small intestines the villi are still more injected; the jejunum and ileum are often a bright red colour; the mucous membrane is softened, and in part stripped of epithelium. The solitary glands and Peyer's patches present a great variety of appearances; Dr. Murchison says they are smaller and less vascular in the diseased than the healthy animal; generally, however, they are congested, and are covered with an opaque sloughy exudation. The lungs are frequently emphysematous. Entozoa are unusually numerous in the heart and voluntary muscles. The blood is black and fluid after death, containing, according to Dr. Beale, "a peculiar granular matter;" of which Dr. Beale remarks, "possibly this granular matter may be the poison." There is ecchymosis and effusion of the blood after death under many parts of the skin and mucous membranes.

The diagnosis of the disease from other affections is a matter of the greatest practical importance, for we have seen that the whole question of the existence or non-existence of cattle plague in Ireland turned on this mooted point—Whether the epizootic which appeared last month in the county Down was rinderpest or not.

MATER MISERICORDIÆ HOSPITAL. CLINICAL LECTURES ON DISEASES OF THE HEART.

By Dr. HAYDEN,
PHYSICIAN TO THE HOSPITAL.

MITRAL OBSTRUCTION.

[Concluded from Vol. ii., page 7.]

JULY 2nd: Since the preceding lecture was delivered, the patient, Jane M., whose case is given as the last in the category, has died. For several days she had been somnolent, occasionally delirious, and expectorating large quantities of dark grumous blood; the radial pulse had entirely failed; and on Friday, 29th June, she sank quietly at two

p.m. The post-mortem examination, made in presence of the class, and of which I subjoin a summary, was entirely confirmatory of the diagnosis. I may remark here that whilst in hospital this patient was examined by several medical gentlemen, and was repeatedly pointed out by me to visitors and to the class as affording a typical illustration of stenosis of the mitral orifice.

The liver was contracted transversely, and elongated vertically, and in a condition evidently the result of tight lacing in early life, but otherwise healthy; kidneys and other abdominal organs healthy; both pleura and also pericardium nearly full of serum; right lung studded with masses of extravasated and solidified blood, varying in size from a pea to a pullet's egg; left lung presented only a single such collection, of medium size, near its anterior edge; heart enlarged, weighing 12½ oz., with one inch of the aorta and pulmonary artery attached; right ventricle dilated and thickened, and containing a thick flake of yellow fibrine, which extended into the pulmonary artery; left auricle greatly dilated, and its walls much hypertrophied; pulmonary veins likewise much dilated; left ventricle hypertrophied, but scarcely dilated; right auriculo-ventricular orifice much dilated, admitting four fingers with ease; left auriculo-ventricular orifice greatly contracted, and barely admitting the tip of the index finger passed from the auricle; both segments of the mitral valve were greatly thickened, of cartilagenous consistence, but flexible, white, and perfectly smooth on the surface and edges; when water was poured into the ventricle, the aorta being closed by compression with the fingers, the segments of the mitral valve fell together evenly, and prevented regurgitation into the auricle; the anterior and right segment of the valve was the thicker of the two, and one of the chordæ tendinæ extending from it to the anterior wall of the ventricle had become as thick as the point of the little finger; the aortic valves were perfectly healthy, and retained water.

Thus, then, this case being included, the post-mortem examinations were four in number, and in three instances confirmed the diagnosis. In the fourth instance (the case of aphasia) the diagnosis of mitral obstruction was not made, for reasons previously given; but this only shows that the evidence relied upon as warranting the differential diagnosis of obstruction at the mitral orifice occasionally fails, where serious complication exists to mask or derange it, and still more frequently in the period of cardiac asthenia of more or less protracted duration immediately preceding death; it does not in any measure diminish the positive value of that evidence when present, and the circumstances under which a diagnosis cannot be arrived at from want of the usual and distinctive signs and symptoms—namely, those of impending death—render it of very little consequence whether the disease be identified or not.

GASTEIN AND ITS THERMAL SPRINGS.

By Dr. G. PROELL.

"GASTANA TANTUM UNA."

GASTEIN is magnificently situated in the Province of Salzburg, in Austria. It is but a small village, traversed by a torrent called the Ache, close by a marvellously picturesque waterfall, in the midst of a valley 3135 feet above the level of the sea, and surrounded by the loftiest central Alps. The whole valley is called Gastein, and there are four villages which share the name, and are distinguished by a prefix—viz., Dorf-Gastein, at the entrance of the valley; Hof-Gastein, about the middle; Böck-Gastein, at the other extremity; and Bad-Gastein, which alone has made the name known throughout the world. The nearest railway station is Salzburg, about fourteen hours by mail-coach or post-carriage.

From the springs at Gastein it is calculated that 132,000 cubic feet of the water are given off every twenty-four hours. This water is pure and limpid—the purest in the world. It has no odour; it tastes like distilled water, and

has the same specific gravity. It is naturally warm, 112° Fahr., so that it has to be cooled for bathing. It is drunk either at the natural temperature, or, in some cases, after getting cold.

In 1862, I evaporated a large quantity, and only obtained 3.5 parts of solid matter in 10,000. This residue I submitted to Professor Redtenbacher of Vienna, who found it to consist of the following ingredients:—

(L'analyse spectral a fait découvrir la présence élatante de deux nouveaux métalloïdes: le rubidium et caesium).

Sur 10,000 parties liquides, on a trouvé:

1. Sulphate of soda	2.038
2. Chloride of sodium	0.466
3. Silica	0.495
4. Carbonate of lime	0.195
5. Sulphate of potass	0.134
6. Sulphate of lithia	0.035
7. Carbonate of magnesia	0.016
8. Phosphates	0.006
9. Carbonate of oxyd of iron	0.004

Total 3.389

By the spectral analysis rubidium and caesium have both been demonstrated.

Having almost no solid ingredients, and possessing the appearance of pure distilled water, the springs of Gastein are generally classified amongst the chemically indifferent; yet the baths enjoy the reputation of being the most powerful remedial agent in certain spinal and nervous diseases, and many cases of paralysis and prostration (mental and physical) have been relieved, after a vain trial of all other remedies. I have endeavoured to prove, and believe my numerous experiments demonstrate that the water of Gastein is a much better conductor of electricity than ordinary or even distilled water, and to this may perhaps be due some of its effects.

The Gastein waters have an eminently astringent and tonic effect upon the patients. After a bath the pores are closed, and perspiration impeded, the circulation is less active, and constipation of the bowels is frequently produced. The cases for which the course is prescribed are, very chronic diseases of the cerebro-spinal system, paralysis and debility, caused by excesses of all kinds, by too early marriages, by vice, by loss of blood, or by chronic exhausting diseases, the consequences of over-work of brain, certain female diseases of debility, mercurialism, chronic ulcers, caries of the bones, as well as very chronic rheumatism and gout, have all been benefited.

The cases most adapted for the treatment—those in which there is phlegmatic temperament, absence of fever, natural gaiety, a thoroughly contented disposition, and willingness in all things to implicitly obey the medical adviser. On the other hand, feverishness, sanguine temperament, discontented disposition, self-will, and a readiness to disobey the doctor's rules, are contra-indications.

Gastein has been called the "spring of youth," from the renewed strength that old age finds there, but very young children may also try the baths.

Gastein must never be recommended in liver complaints, or where there is any predisposition to consumption or chest disease. The remedy is applied in many ways. The course or cure consists essentially of the baths, but so great is the virtue of the water credited that it is used in almost every possible manner. Thus vapour-baths are invariably tried when the ordinary course is not effectual, or, as is often the case, is too powerful. There is also the mode of inhalation in vogue. When neither of these, the water is taken into the stomach, and this also very often as an adjunct. As a local bath of every description it is prescribed—*e. g.*, as collyrium in diseases of the eyes; a mouth-wash for alveolar abscess or caries; as a gargle for some forms of angina; an ear-injection in caries of the small bones of the ear; an injection for many female complaints; enema for habitual constipation from deficient tone of the muscular coat; as a sitz-bath in a

great variety of cases, and, in fact, in every possible mode of local application.

The water keeps its purity and its electrical properties for many years, so that it is often exported for those who cannot visit Gastein.

The cure can be taken at Hof-Gastein, one hour and a half distant from Bad-Gastein. The place is sometimes preferred, as cheaper and more retired, but there are few means of recreation, and the course cannot be so well carried out.

The Gastein season is from the middle of May to the end of September, and, on account of the small number of houses, it is necessary to write two or three months in advance, when the patient is desirous of taking the cure in the height of the season—from the middle of July to the middle of August. It is, however, the experience of all the physicians that it is better for those who go only for health to choose either the spring or the autumn. The cold does not interfere with the treatment, as there are bath-rooms in all the houses, and no perspiration follows; besides, the weather is generally much finer.

Apart from the thermal waters, the climate of Gastein has great influence. I have made a record of the meteorological changes during the last fifteen years, but can only offer in this place the results of these masses of figures.

In summer, Bad-Gastein is the coolest refuge in Europe. There is frequent rain in the hottest months; sometimes snow falls in the height of the season. Yet the humidity is not injurious; on the contrary, it renders the baths more easily supported. The great advantage is the absence of wind. Except from the south, wind can get no access, and from that quarter it seldom blows. There is no danger in walking about in slight rain, for the evaporation is very rapid, at a height where the atmospheric pressure is reduced to twenty-five inches. The mean annual temperature is only 4° Reaumur. In the thermal season it rises to 10°.5 Reaumur. There are in summer, 17 rainy days per month; in spring and autumn, only 9.

The ozonimeter always stands at the highest degrees. The humidity, as already stated, is excessive; nevertheless, it is not injurious. Like the gods of the ancients, at Gastein we walk surrounded by clouds. To this little sketch, I need only add that the hotels at Gastein are excellent, added to which, private apartments may be hired. Every comfort and luxury is to be found in the season. For persons in health there is the opportunity of exploring some of the most picturesque mountain scenery in Europe, and scaling the loftiest regions of the central Alps. Even the invalid will find numerous excursions he is capable of undertaking, and pic-nics are constantly being arranged. Besides the geology of the district never fails to occupy those disposed to science; while the history of Gastein for the last 1000 years is full of romantic legends, &c., to pass the time indoors. The prices vary according to the time of year and the advantages. The cheapest months are May and September; the dearest time is from July to the middle of August. Apartments in the central part of Gastein are more difficult to obtain than in the lower. The prices for rooms vary from two to twenty-five Austrian florins a week for a bed-room. There are two *tables d'hôte* at one o'clock for one florin, and at three o'clock for two florins (not including wine); in the evening there is no *table d'hôte*. The price for one bath daily, without linen or fire (in the stoves) is four florins. There is also a government tax for each person who remains more than six days, and a music tax of three florins. The band plays from June till the end of August. At Gastein a great advantage is a covered glass gallery, 420 feet long, where there is a little saloon, with a piano for ladies; a library, and an establishment for drinking whey and mineral water. Journals of all languages are also to be found here.

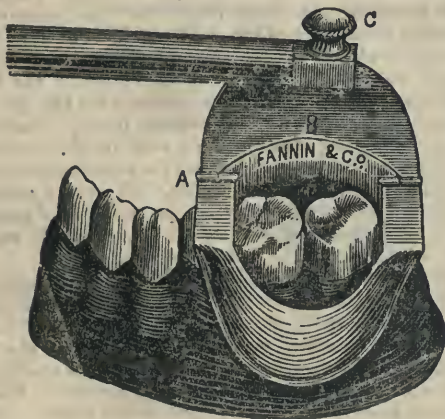

ATTENTION is directed to the frequency of deafness among the offspring of consanguinous marriages.

DENTAL INSULATOR FOR ANÆSTHETIC OPERATIONS.

By FRANCIS McCLEAN, Junior.

DENTAL SURGEON TO THE CITY OF DUBLIN HOSPITAL, ETC.

SOME months since when the anæsthetic spray producer was on its trial, it was reported to be most successful in all minor surgical operations, excepting the extraction of teeth, in which most painful one its efficiency was only doubtful. I then laid before the readers of THE MEDICAL PRESS AND CIRCULAR, in its issue for March 14, 1866, the result of my experiments with it in dental operations, and I arrived at the conclusion "that the anæsthetic effect is complete whenever the spray can be properly applied." In its application I found a number of difficulties to contend with, but the greatest was to prevent the tongue and cheek from interfering with the ether spray when applying it to the teeth in the lower jaw. With a view to obviate this difficulty, I have contrived an instrument which can be easily used without the assistance of a third party—which will expose an uninterrupted view of the tooth to be extracted, and of the parts necessary for the spray to play on—very simple in its construction, and can be held in the mouth lightly by one hand of the operator, while his other is engaged directing the ether jet.

The instrument, manufactured of silver, consists of two valves, curved so as to give a sufficient space round the teeth to which they may be applied for the introduction of the double jet, and hinged to each other at A, to allow them to adapt themselves closely to the lower part of the jaw. To the inside is attached the plate B for depressing the tongue, which it effects without controlling its movements or causing the unpleasant sense of sickening which the use of the spatula is subject to. To this depressing plate is attached the handle movable on a pivot C, so as to allow of its being drawn to one side. When the instrument is placed *in situ*, it perfectly protects the tongue and cheek from the ether, the two valves, being pressed together by the parts, fit closely to the gum covering the lower part of the alveolar process, while the tooth and its surrounding parts are seen in the centre perfectly insulated. That represented in the woodcut is for the left side.

The patient keeping the mouth well open so as to allow the ether to evaporate quickly, can at the same time work the hand-ball bellows as the operator may direct. The moment the parts become blanched the surgeon dexterously withdraws all, and without delay extracts the tooth, which I have no hesitation in saying can be done painlessly in a large majority of cases, provided you use anhydrous ether with Richardson's double spray producer in proper working order. Too much attention cannot be given to these requirements, for in cases in which I have seen the apparatus fail, and so fall into disrepute, the cause have been its not working properly and the im-

purity of the ether used. With regard to the objection of the ether entering the throat and tickling the fauces for the few seconds which the application requires, this can be avoided by protecting it with a napkin, and requiring the patient to breathe through the nose.

This instrument, to which I have given the name Dental Insulator, I place before the profession as the result of my exertions to facilitate the use of local anæsthesia in dental operations, not doing so, however, without fully testing its efficacy. Having done so, I feel satisfied that by its aid we will have more success in operating on the teeth of the lower jaw than has hitherto been experienced.

SCROTAL HERNIA, COMPLICATED WITH ORCHITIS.

By Dr. W. L. HEPBURN.

ON June 3rd I was requested to visit Mr. R., æt. 45, married, and holding a responsible situation in this city. He stated that, after a long walk the evening previous to my visit, he was suddenly seized with a pain in the right groin, accompanied with nausea and vomiting. On examining the situation of the pain, I found it occupied by an old hernia, which, to use his own words, "could never be made to go back," and from its size, as also from its being not unfrequently the seat of pain, this for years had been a source of discomfort to him. His countenance was anxious; hands and feet cold; pulse 110, and weak; tongue covered with a creamy feu. His bowels having been confined, he took some cathartic medicine, which, however, did not operate.

On my requesting to be allowed to examine the tumour, he hesitated, saying that of course I had seen such cases before, and that unless I considered it absolutely necessary he would rather I should not subject him to the exposure. However, on my pressing him, he consented, and the appearances which the tumour presented were the following: The scrotum at the right side was enlarged and red; at its posterior and lower part might be felt a well-defined hardness; on its anterior surface was the hernia.

I confess that at first sight I was not a little puzzled as to the nature of this case. The circumstances of his being advanced in life and married, its sudden occurrence after exertion, the presence of constipation, vomiting, and tenderness extending up the abdomen—above all, the fact of there having existed an old hernia, clearly pointed out the case as one of strangulated scrotal hernia.

On the other hand, the position and peculiar hard feel of the tumour, the sinking sensation complained of when I pressed it, a similar feeling experienced on pressing the opposite testicle, despite the absence of any evidence of gonorrhœa, and the patient's silence respecting it, in my mind pointed out the disease as epididymitis. The treatment pursued was leeching and subsequent fomentation, with the following lotion:—

R. Ext. belladonnæ, gr. 60.

Decocti papaveris, ℥x. M. Ft. lotio.

Also a mixture, composed of:—Liq. ammoniæ acet., ℥i.; Aq. lauro cevasi, ℥iss.; Tr. hyoscyami, ℥ii.; Vini antimonialis, ℥ii. M. Take two tablespoonsful every fourth hour.

On my again seeing him, he expressed himself much relieved by the treatment adopted. The tumour had lost much of its tenderness, and was somewhat reduced in size.

The following day confirmed the correctness of my diagnosis, inasmuch as a gonorrhœal discharge had made its appearance, and continued till arrested by treatment. The testicle is now reduced to its ordinary size, the hernia remaining as before.

Mr. Acton has recorded a case, in which a mistake might have occurred to an inexperienced eye, even more easily than in the foregoing instance.

The testicle having been retained in the inguinal canal, the subject of the deformity, contracted a gonorrhœa, terminating in metastasis, the influenced organ presenting, at first sight, many of the characteristics of strangulated inguinal hernia.

Hospital Reports.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

CASES UNDER THE CARE OF MR. PORTER,

SENIOR SURGEON TO THE HOSPITAL.

[Reported by ARTHUR WYNNE FOOT, M.D.]

(Continued from page 10.)

CHRONIC ECZEMA ON THE LEG, TREATED WITH CARBOLIC ACID OINTMENT.

Case 27.—A man, 43 years of age, of intemperate habits, came under the care of Mr. Porter during the preceding month for an eczematous eruption, in various stages, upon the right leg, covering the limb more or less thickly from the knee to the ankle. The disease had been on him since last Christmas; it commenced in the thin skin of the flexure of the knee-joint with "a little bit of an itching and a watery blister." The leg was, at the time of his application, more or less covered with crusts of the inspissated secretion from the ruptured vesicles, with here and there moist excoriations and red patches of raw cutis, denuded by the friction of his clothes and by his attempts to allay the constant itching, which was very severe at night. The cutaneous disease was not complicated with varicose veins or ulceration of the leg, nor could its appearance be traced to any local irritation. Mr. Porter, therefore, directed his attention to the constitutional treatment of the case and the alleviation of its most distressing local symptom—the intense itching. The mineral acids and bark were administered, and an ointment composed of two drachms of carbohc acid, two drachms of glycerine, and an ounce of lard, applied two or three times a day, according as his occupation of groom permitted. Under the use of these remedies the pruritus has become much lessened, the oozing of the watery ichor, which gives to the lower extremity when affected with eczema the appropriate name of "weeping leg," has been checked, and the skin has commenced to assume a healthy appearance in those parts where the eruption had been comparatively recent.

CHRONIC ENLARGEMENT OF THE TONSILS—TREATMENT WITH CAUSTICS—SUBSEQUENT AMPUTATION WITH A TONSIL GUILLOTINE.

Case 28.—The subject of this case was a boy, eight years of age, who had been for some time suffering from enlargement of the tonsils to such a degree as to interfere with deglutition, causing him also to snore loudly at night, and to speak with a nasal tone of voice; he was also frequently deaf. While eating his meals he appeared to hurry as much as possible through the act of swallowing, as if any delay in that act would cause him to choke. The enlarged glands very much encroached upon the isthmus faucium, and pressed upwards against the posterior nares, so that while food was in the act of passing through the posterior aperture of the oral cavity, he was obliged to suspend respiration. One tonsil was removed by Mr. Porter with a tonsil guillotine, and for some time there was a considerable abatement of those symptoms which called for the operation. To the other enlarged tonsil the solid nitrate of silver was frequently applied, and subsequently the London paste—a caustic composed of six parts of caustic lime, seven parts of caustic soda, and as much absolute alcohol as will make these into a paste. This application caused great pain, and produced a very thin slough, merely a superficial film of eschar, without any reduction in size of the part. Mr. Porter, therefore, to avoid delay, removed the second gland in the same manner as the former one; there was no hæmorrhage of any account on either occasion.

CONTRACTION AND FIBROUS ANCHYLOSIS OF THE KNEE-JOINT—TENOTOMY—FORCIBLE EXTENSION OF THE LEG UNDER THE INFLUENCE OF CHLOROFORM.

Case 29.—A little girl, aged 11, was admitted into hospital under Mr. Porter's care, with her right leg flexed nearly to a right angle with the femur—the angular ankylosis of Dr. Little—the head of the tibiapartially luxated backwards, and no enlargement of the end of the femur, the result of inflammatory action in the joint, the consequence of an injury received some years ago. She had not been able to put that foot to the ground or near it for a long time, and supported herself with a stick in walking. The joint was incapable of performing any of its motions, and the muscles of the thigh were much wasted. Having been brought under the influence of chloroform, the tendons of the hamstring muscles were subcutaneously divided as near to their insertion as possible, and this having been done, the leg was forcibly extended towards a straight line with the femur. The angle which the leg made with the thigh having been very much increased, a screw extending iron splint, well padded, was applied along the posterior part of the limb, and a moderate amount of extension maintained. Cold lotion was kept over the knee-joint, and subsequently a sand-bag was laid upon the patella. No inflammatory action resulted from this treatment, and the leg is being gradually more extended by the action of the screw. From the appearance of the child it could readily be inferred that the knee-joint had been the seat of strumous inflammation, which is so much more frequently a cause of ankylosis and deformity than any other. The method of treatment adopted by Mr. Porter was a combination of the practice of Stromeyer of Hannover, and of that recommended by Dieffenbach and Langenbeck of Berlin; the former divided the tendons subcutaneously, and did not forcibly extend the joint; the latter did not divide the tendons, but forcibly stretched the parts, Langenbeck objecting to the previous division of the tendons that the wounds made by the tenotome will gape during extension, and air be sucked in. In support of this opinion, Mr. Barwell mentions that he was present at an operation for extending the knee, in which, both hamstrings being divided at the time, the skin in the popliteal region split from side to side. The amount of extending force applied by Mr. Porter was regulated so as not to incur the risk of such an event. It is also known that tenotomy in the young is more necessary in dealing with contracted joints than in older persons, because the muscles of children, though weaker, are more apt to retract after extension and to thereby reproduce deformities than those of adults—a result which is obviated by previous division of their tendons.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

IRRITABLE AORTA.

PULSATION of the abdominal aorta, sensible to the patient, often attended with a peculiar uneasiness, and sometimes with positive pain, constitute a group of symptoms which must be familiar to the practical physician as a source of doubt and difficulty in diagnosis, and of much anxiety in regard to prognosis. This condition, Dr. Lyons observes, is common to the male and female, occurs in middle life—30 to 50 years of age—is liable to be confounded with aneurism, and denotes in his experience a condition of the aortic tube, in which there is present much irritation of its coats, with a tendency to atheromatous deposit, temporary dilatation of the vessel in a more or less limited portion of its extent, and a liability, if the morbid state be not checked, to the ultimate formation of some form of true or false aneurism. When associated with pain in the back and any form of tumefaction of parts in the abdominal cavity

which lie in contact with the aorta and receive a communicated pulsation, the liability to mistake the condition under consideration for aneurism is still further enhanced.

The principal phenomena of this morbid state and the elements of clinical diagnosis are well exemplified in the following cases, which have occurred in Dr. Lyons's practice:—

Case 1.—The patient, a man, aged about 40, and in fair average condition, was admitted into the Whitworth Hospital complaining of general debility, with a good deal of uneasiness, hardly amounting to pain, in the back, and also referred to the region between the xiphoid cartilage and the umbilicus. A certain amount of beating or "bealing" sensation was likewise experienced. The patient was placed in bed and directed to remain in the horizontal position for many days consecutively; a mild purgative was exhibited by the mouth, and the bowels were well cleared by an enema. The action of the heart and the radial pulse were normal throughout. On careful exploration and deep palpation in the mesial line of the abdomen, between the xiphoid cartilage and the umbilicus, the abdominal aorta could be readily detected beating with greatly increased force; it was somewhat tender to pressure, freely movable, and on minute examination by the fingers of both hands, it was found to be slightly dilated through about three inches of its extent; palpation elicited some tenderness in the course of the vessel, but not nearly so much in this case as in others subsequently to be noticed. On applying the stethoscope a distinctly single impulse and single sound were observable. The sound, audible on moderate pressure, was that of a short dull "thud," the normal *bruit de choc* of the abdominal aorta; on more firm pressure a slight murmur was elicited. The force of the aortic pulsation in this case was in marked contrast to that of the heart's shock, the impact of the radial arteries, and the contractile force of the iliac and femoral arteries, and no doubt could exist on the mind of any clinical observer that a certain portion of the abdominal aorta was in a condition of localised excitement, irritability, and increased size, exhibiting at the same time a very manifest increase in pulsatile force.

Perfect rest in the horizontal position was enjoined both day and night for many days in succession, the bowels were kept well cleared, sedatives were administered, and an ointment, containing one grain of digitaline to the ounce, was directed to be rubbed over the part in front and behind; mild but nutritious food was administered. Under this treatment the irritation, uneasiness, pulsation, and dilated state of the aorta gradually subsided. The patient felt himself so very greatly relieved that he believed himself cured, and feeling the irksomeness of restraint and confinement to bed intolerable, he left hospital. The dilatation of the vessel in this case on admission might be roughly estimated as equalling about one-third of the calibre of the vessel, and it was restored as nearly as could be estimated to its normal size and pulsation within the period mentioned. That a very much longer period of rest is required to restore the vessel to a permanently healthy state the experience of other cases in Dr. Lyons's practice very fully shows.

Case 2.—The patient was a man, aged about 45, a field labourer, with nothing unusual in his history, and who could give no account of any injury or special act of over-exertion to account for the condition and symptoms which he presented. After what has been mentioned more fully about the phenomena presented in the previous case, it may be briefly stated that those exhibited by this patient far exceeded them in severity of suffering and in the force of pulsation presented in the vessel.

The same measures were adopted. A mild purgative was administered, and the lower bowel well cleared by enemata prior to examination. The patient was rigidly restricted to the horizontal position. The pulse, heart, and great vessels were found to be everywhere normal in force and rate. Very marked pain was complained of in the back corresponding to the upper lumbar vertebra, and

very decided sensations of pain and distress were elicited on deep palpation and careful exploration of the abdominal aorta. This vessel was found to be dilated by about one-fourth of its diameter for some three inches of its extent, and the force of its pulsation was increased to a very manifest degree, while the tube was tender to the touch. On applying the stethoscope a very forcible impulse and sound were perceptible, but there was an absence of bruit except on firm pressure.

The patient was kept in bed, the bowels were gently evacuated, sedatives were administered, digitaline ointment rubbed in three or four times a day, and mild unirritating though nutritious diet was allowed. In about a fortnight the patient experienced very sensible relief to all his symptoms; the pain in the back disappeared, the sense of pulsation in the abdomen was lost, and the vessel sensibly diminished in volume to the touch and in force of its beat, while the tenderness to pressure was reduced to a minimum. In from four to five weeks such very marked improvement took place in the patient's general condition and local symptoms that he was no longer willing to submit to the restraint imposed on him, and requested to be discharged. He left hospital considering himself all but well.

Cases 3, 4, and 5.—These cases all occurred in females, aged respectively about 45, 50, and 60. All three were mothers of families; in no instance was there anything special in the history beyond active occupation in household cares. No incident attended with very unusual muscular strain to the back could be traced, and no previous accident or injury by a fall, crush, or impact of a ponderous body could be ascertained to have ever been experienced.

In case No. 3 the period of suffering extended over half a year. When at its worst this case exhibited a very strong pulsation over and to the left side of lumbar vertebra; there was no bruit whatever. Examination and palpation caused great pain and distress in the part of the vessel explored, and likewise in the back, extending down into the left side towards the hip. Independently of any examination much pain of a burning and grating character was complained of for days together, and the patient likewise suffered from palpitation of the vessel. The localised aortic pulsation in this case was the more remarkable that the patient presented an unusually feeble impulse of the heart, and the radial, femoral, and other vessels beat with a singular degree of faintness. The abdominal aorta in this case was fully twice its normal diameter, and its pulsation most powerful, though never diastolic.

In this case the patient, being a person of unusual intelligence, submitted with great fortitude to the conditions imposed. Rest in the horizontal position was most absolutely maintained for a period of fully three months. Wet cupping to the loins, sedatives, mild evanescents, digitaline ointment, belladonna and aconite liniments, with the emplastra ferri et belladonnae in equal parts, were employed from time to time as occasion demanded. As the result of a slow and gradual process, amendment was by degrees established, and after an interval of about nine months a very satisfactory condition of general health and freedom from local suffering was brought about, and, coincident with this, gradual subsidence of the aorta to its normal calibre was observable, while the forcible pulsation also gradually gave place to the more normal action of the vessel. Dr. Lyons believes that in this case the patient has had to thank her own fortitude in following through a protracted period very irksome advice for escape from the formation of aneurism.

Case 4 presented in many respects a very similar history; but, neither circumstances, nor the patient's disposition, allowed of such a protracted period of rest; and consequently the improvement in the local condition has not been so decided. But many months have elapsed without ill result.

Case 5 is still under observation, and does not admit of any conclusions being as yet drawn from the facts hitherto observed. From the loaded state of the intestines

Foreign Medical Literature.

ON

IRRADIATION ON SYMMETRICAL PARTS OF THE OPPOSITE SIDE.

By F. Z. ERMERINS, Professor at Groningen.

Translated from the *Nederlandsch Archief voor Genees- en Natuurkunde*, 1e Deel, 4e Aflevering, Utrecht, 1865, p. 473.

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.R.I.A.,
HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE
NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY
OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURIS-
PRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

J. T., aged 53, was admitted into the University Hospital at Groningen on the 17th March, 1863, and died there on the 24th March, 1864. He suffered from paralysis of the lower limbs. He imagined also that he had a urinary fistula, but on examination this proved to be nothing more than an erythematous condition of the skin of the perineum and surrounding parts, as the result of enuresis. He sometimes complained of pains in the region of the upper part of the bladder, sometimes of pains in the urethra; but no cause could be discovered for them, they appeared to be neuralgic. During the first months he still got up occasionally, during the latter months he never left his bed. Gangrene *ex decubitu* now set in, the right trochanter being at last completely stripped, a necrosed spot of at least the size of the palm of the hand forming around it. On the sacrum, too, and on the left trochanter, mortification set in, though in a less degree, as the patient lay mostly on his right side. Although he had no anæsthesia, he suffered no pain in these situations. The legs were, even at the last, although somewhat, still not greatly emaciated; likewise the arms; the face presented no emaciation. The eyes had something weak and languid in their expression, otherwise there was no disturbance in their function, nor in those of the organs of hearing and speech. His intellect continued clear. In the intermittent feverish attacks, which from time to time occurred, he complained often of pains in the limbs, which did not depend upon muscular spasm.

The history of his case gave but little information. We learned only that he had probably for a long time led an irregular life. It moreover appeared that the disease had begun to develop itself several years before he applied at the hospital, and that his present state had gradually come on.

In the latter weeks of his life, in frosty weather, he moved a hot-water jar, which lay at the foot of his bed, higher up near his body, and burned himself on the inside of the left thigh. This was not mentioned until after the lapse of a day or two. I then found in the seat of the burn a small eschar, which gave him pain. But he now felt pain not only in the burned part of the left thigh, but also a painful sensation, although less violent, in the corresponding part of the right thigh, which he distinctly and repeatedly pointed out; for the symptom lasted some days, and ceased when the burn was healed. The painful part of the right thigh exhibited neither change of colour of the skin, swelling, nor anything unusual.

Of the treatment I shall not say much; anti-paralytic means were tried, but in vain. The treatment was often modified in consequence of intermittent fever, gastric symptoms, or other incidental circumstances. The post-mortem examination showed satisfactorily that all efforts to cure his principal ailment must have been in vain. The report of it is as follows:—

The skull and vertebral column were opened. The arachnoid of the brain and spinal cord was opaque and

the deceptive phenomena of tumour were at first much more marked in this than in any of the other cases cited. In studying the phenomena presented by these cases, and considering the light and illustration thrown upon them by what he has observed in similar cases during life, and in the pathological anatomy of the aortic tube in post-mortem examinations, Dr. Lyons is of opinion that we may conclude that there exists—

1. A state of localized and temporary irritation of the abdominal aorta, attended by a tender and sometimes painful condition of the coats of the vessel, and marked by an increased calibre of its tube and more forcible pulsation, amounting, in some instances, to violent localized throbbing, and with pain and distress more or less considerable, and conveyed to a greater or less distance along the vessel and the parts contiguous to it, or in connexion with it by community of nervous supply.

2. That it is probable this condition is, in the first instance, one of subacute localized aortitis.

3. That this condition is favourable to the ultimate development of atheromatous deposit, consequent injury to the elastic and contractile force of the aorta, and that the upright position favours the distension of the vessel by the pressure of the vertical column of blood.

4. That, consequently, patients labouring under this condition are in the predicament to favour the formation of a condition of true aneurism by permanent dilatation of all the coats of the vessel, if the state of irritation and distension be maintained, until by loss of organic tonicity, or by atheromatous deposit, the walls of the vessel are dilated, and can no longer contract.

5. That, while in this condition, sudden exertion or local injury by blows, crushing weights, &c., or over-distension of the vessel, readily leads to rupture of the internal and middle coats, and so conduces to the occurrence of false aneurism in any of its forms.

6. That absolute rest in the horizontal position, so as to remove the distensile force of the superincumbent column of blood from the weakened and dilated portion of the vessel, is a necessary part of the process of cure.

7. That the diagnosis between this state of partial dilatation and temporary irritation of the aorta and any of the forms of actual aneurism is to be based on the condition of the vessel as determined by most careful digital exploration (after the bowels have been well evacuated); by the absence of bruit except on pressure; by the mobility of the aorta and the very elongated fusiform shape it assumes; by the absence of true diastolic throb; and, lastly, by the effect of horizontal rest in decidedly diminishing, not alone the pain, distress, and suffering experienced by the patient, but in sensibly reducing the force and volume of the aortic pulsation.

That great care in diagnosis and prognosis is demanded by cases like those under consideration is obvious. An aneurism overlooked will lead to all the misery and appalling fatality of sudden, unexpected, and unprovided-for death. An aneurism assumed when it does not exist leads to unnecessary alarm, and ultimately recoils on the reputation of the practitioner concerned. Amongst the singular instances of abdominal pulsations the source of some doubt and much anxiety with which he has met, Dr. Lyons instanced the case of a very powerful pulsation sensible to a patient low down and far to the right in the right hypochondriac region. On applying the stethoscope in this situation a distinct double sound was audible. The phenomena were traceable to an aggravated form of temporarily enlarged and highly congested liver, which touched the heart on the left side and the parietes of the abdomen on the other, and, like the balk of timber conveying the ticking of a watch from one end to the other, transmitted the cardiac sounds and impulse in full intensity. Under treatment the liver returned to its normal volume, and the pulsation and sounds ceased in the right hypochondriac.

MRS. RAPEE has presented £500 to the General Infirmary, Aylesbury, in memory of her late husband.

thickened; the vessels of the pia mater were highly congested. On the cerebral arachnoid was a milky exudation. On the surface of the brain the depth and width of the sulci between the convolutions struck the eye. On taking out the brain there was a considerable amount of serum in the cavity of the occipital bone. The cerebral substance was to external appearance normal; to the touch it seemed to have the ordinary consistence. The ventricles were evidently distended; around them too the cerebral substance was not soft, but possessed the usual firmness. Atrophy of the brain therefore clearly existed. The condition of the spinal cord corresponded to this state of the brain. It was not here or there, but throughout slighter than usual, and there was a good deal of serum between its membranes. The body was subsequently used for the dissecting-room, and the fineness of the peripheral nerves then attracted attention. The cerebellum presented no certain sign of atrophy, but it was evidently in a state of softening. It could not be touched without falling to pieces. On the whole, therefore, we had atrophy of the brain and spinal cord, with softening of the cerebellum.

A circumstance, not indeed connected with the disease, but still deserving mention, was the existence of a symmetry between the right and left hemisphere of the brain. The latter exhibited a certain preponderance over the former. At the base of the brain the grooves in which the anterior and middle lobes lie were deeper on the left than on the right side, so the lobes were there more developed than on the right.

In the cavity of the thorax the lungs were found to be normal, except that they were attached by false membranes to the thoracic wall, as is often the case in the bodies of adults. The heart was rather small than large, otherwise it was normal.

In the sulci cordis was a considerable quantity of fat, corresponding to that found in the abdominal cavity; the valves were normal; there was no atheroma of the arteries.

In the abdomen the great development of fat, especially in the omentum majus, was remarkable. The liver was not large; its edges were indeed rather sharp, but there was no trace of cirrhosis. The spleen exhibited nothing unusual. On raising the omentum a portion of the small intestine struck the eye with its completely blood-red colour. Over the inferior part of the jejunum ran a string of false membrane, which was not broad, but cord-like, springing from and terminating in the mesentery. This false membrane extended nearly to the inferior boundary of the blood-red portion of intestine, yet, in my opinion, could have exercised no influence on this condition; there was no incarceration or rather constriction, nor had there been any symptoms of such during life. The portion of intestine in question was a part of the jejunum, in length rather more than a foot and a half. It was so coloured by an effusion of blood in the subserous connective tissue; the mucous membrane exhibited no trace of hyperæmia; the intestine contained no ecchymosed blood; the peritoneal investment of the portion of intestine was smooth, shining, and transparent. The blood extravasated in the subperitoneal connective tissue appeared so strongly through the latter as to make one suppose that he was looking at an intestine which had been dragged through a basin of uncoagulated blood, or which had been smeared with blood.

In the left kidney we found distinct fatty infiltration, white spots being formed throughout in the renal substance, especially in the cortical portion. In the right kidney the same was observable, though in a slighter degree; but in the latter the pelvis and calyces were undoubtedly dilated. In the bladder nothing abnormal was found; the urethra was not examined.

So far my history of the facts. I have recorded it chiefly on account of the existence of pain in the part of the opposite side corresponding to the seat of the affection. On this subject I shall take leave in the first place to quote the following words from Schiff's *Lehrbuch der Phy-*

siologie des Menschen: "Of the anatomical conditions under which one half of the body may become insensible from disease of the medulla, I have already treated. We have also here seen that destruction of only one half of the medulla is not sufficient to make the one side of the body anæsthetic, and that only the layer of æsthesodic substance situated most externally corresponds preëminently to one half of the body, and that the opposite. When I here say preëminently, and when I in general only approximately maintain a separation of the sensory systems of the two halves of the body, I rest less upon the results of experiments than upon a pathological observation of Boyer, *Traité des maladies chirurgicales*, t. vii., p. 9), which as yet stands alone."

Schiff further communicates Boyer's case in a few words. I take it from the latter writer:—

"A drummer was disputing with a drunken comrade; the latter, not being able to reach him, flung his sabre at him at a great distance, and at the moment when, wishing to withdraw, he turned his back upon him. The point of the weapon struck the upper and back part of the neck. The wounded man immediately felt his legs give way under him and fell; he was brought the next day to the Hôpital de la Charité.

"The wound, the edges of which were a little contused, was about two inches in length; it was situated at the posterior and upper part of the right side of the neck, immediately below the occipital. My finger could neither measure its depth, nor reach the vertebral column. The right arm had lost its movements, but it preserved all its sensibility. The right leg seemed a little weakened, but was as sensitive as usual. There was slight difficulty of breathing; the pulse was quick, strong, and full. The patient was bled from the arm. The wound was dressed with lint and an emollient cataplasm; a strict regimen and the use of diluent drinks were enforced. On the fourth day the weakness of the leg had quite disappeared; the patient could perform with the forearm some slight movements of extension, but it was impossible for him to bring the limb back again spontaneously into a state of flexion.

"On the thirteenth day the patient had recovered his strength and his appetite; he got up and walked, but the paralysis of the upper extremity was the same. In playing with one of the attendants who pinched him, he perceived that the left side of his body was insensible. He told me of this the next day, and I observed the following phenomena: the left leg and the left side of the trunk preserved the usual size, movements, and activity; but we could pinch, prick, and even cut the skin of all these parts, without the patient feeling or exhibiting the slightest pain; pins were inserted to the depth of three or four lines, and the patient, who had his head turned the other way, did not perceive it. However, extensive touches, such as the application of the flat hand moved along the skin, caused him to experience a kind of sensation, though extremely obscure and slight. This insensibility existed throughout the entire extent of the left foot, leg, and thigh; it was equally complete on the left side of the abdomen; but it ceased abruptly before and behind the median line, with this remarkable peculiarity that in this part, if the patient were pinched on the left side, he asserted that he felt the sensation in a slighter degree at the corresponding part of the right side. A similar demarcation between the right and the left side extended to the skin of the penis and scrotum. The insensibility was equally complete at the left side of the base of the chest; but a little higher up a dull sensation began to be perceptible, and became more manifest in proportion as we examined upwards; so that at the height of the fourth rib, the skin was as sensitive as that of the rest of the body. The left limb was in a perfectly natural state."

Twenty days after his accident, this man left the hospital, cured of the wound in his neck, and experiencing in that part neither pain nor inconvenience, but the arm, the forearm, and the right hand were almost completely

paralysed, and the left side of the body, with the exception of the upper extremity, was in the state of insensibility just described.

"Some months later he came to see us; his state was scarcely changed. The situation of the wound, and the symptoms by which it was accompanied, would lead us to infer that the spinal marrow was engaged, but that it must have been only superficially so."

This is the case referred to by Schiff, to which I shall revert, but in a note in the place above quoted from him, he states that, while writing it, he received a letter from van Deen respecting the same phenomenon. The greater part of this note I omit, because I have asked van Deen himself about his observations upon this subject, and he has communicated them to me. Only these few lines I borrow from Schiff's note:—"I was very anxious to direct the attention of the profession to this point. To the same category belongs also probably what Treviranus reports (*Biologie V.*, p. 370), that in some cases irritation of the one side is said to produce pains in the other."

I now return to the writer of whom he speaks. In Treviranus we read, in the place referred to, this definitely communicated observation:—"I have known a lady in whom a blister applied behind one ear, invariably at the same time gave rise to pain behind the other."

Schiff speaks of Boyer's case as of an isolated observation at the time he quoted it. Meanwhile, this of Treviranus is positive, although we should have wished to have known something more respecting the general state of the woman in whom he made the observation.

The case of which van Deen wrote to Schiff was, as I lately learned from himself, the following:—A lady had been attacked with apoplexy, which left behind it anæsthesia and acinesia of the left side. In this state, on the application of a stimulant (oil of mustard) to the insensible arm, pain was felt by the patient in the arm of the other side.

Van Deen told me also that he had observed something similar in a sufferer from paralysis of one of the lower extremities—namely, on peripheral irritation of the anæsthetic leg, a painful sensation occurred in the other.

Partly in accordance with this is what a doctor of surgery related to van Deen. A patient had undergone amputation of the thigh; the fresh wound was touched in a place where a nerve had been divided. Thereupon pain was felt both in the part touched, and in the corresponding point of the opposite side.

We have therefore, 1st, Boyer's observations; 2nd, that of Treviranus; 3rd, two cases observed by van Deen; 4th, the case orally communicated to him; 5th the case which led me to write the present paper; thus six cases in which undoubtedly sensory impressions were conveyed to the opposite side.

But respecting these cases there is still something very remarkable to be observed—in Boyer's case there was traumatic injury of the spinal cord. The sudden super-vention of paralysis of the legs upon the infliction of the wound, the extension of the symptoms of disturbed nervous function, leave no room for legitimate doubt with respect to Boyer's opinion in this respect. Of the two cases observed by van Deen, in one apoplexy, in the other anæsthesia resulted from a central affection.

In the case observed by myself, an abnormal state of the brain, cerebellum, and spinal cord existed. We have consequently four cases where the phenomenon occurred under pathological conditions of central parts, although these conditions were outwardly different.

In Treviranus' case nothing on this point appears; it is a pity that we do not know more about it. In the case of amputation related to van Deen we have also to lament that we are not more fully informed respecting it. But if we suppose that besides the local reasons for amputation, no morbid affections existed in the system, the communication of the painful sensation to the other side, nevertheless, occurred after an operation, which, from the violence of the shock, must almost necessarily produce a difference

in the functional condition of the spinal cord and brain. The case so briefly touched upon by Treviranus is the only one in which there is no mention of such a state or of the opposite.

From what has been observed I would therefore almost positively venture to lay down that: in order to produce transmission of sensory impressions to the opposite side, certain unknown abnormal conditions of the central parts are necessary. There is no doubt that in the healthy state such transmission does not take place.

Schiff appears in the above-quoted place to refer to an anatomical connexion between the sensitive parts of the right and left side of the spinal cord. Even if this exists, it is certain that in the regular function of the parts the connexion does not manifest itself in outward phenomena, and that consequently the left and right sides are functionally distinct. Under extraordinary circumstances this distinction is removed. As to the nature of these circumstances we know nothing, but they are to be sought in the spinal cord. Perhaps a certain unusualness and violence of irritation is necessary, in order, in this state of the central parts, to enable the transmission to be effected. The sensory nerves appear to me to remain capable of conduction, even where anæsthesia is present. The peripheral impression received by them does not reach the consciousness, but must in reality exist, and must act through the nerve upon the central part; how should the transmission of the impression to the opposite side otherwise be possible? If in the central parts those conveying sensation to the other side have come into action, this action must, according to the law of eccentricity, be transmitted to the periphery. This is all that I, at least, can suggest upon the subject.

Whether, moreover, the phenomenon is as rare as the little mention made of it would lead us to suppose, is doubtful. I imagine that it often occurs without being observed, and that it is often observed without sufficient importance being attributed to it to cause attention to be particularly directed to it. Physiologists attach more importance to such matters than practitioners do, and the latter have more opportunities than the former for making such observations.

SUMMARY OF SCIENCE.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES R. C. TICHBORNE, F.C.S.L., F.R.G.S.I., &c.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

DISINFECTANTS, IN CONNEXION WITH THE CATLE PLAGUE AND OTHER CONTAGIOUS DISEASES.—*Summary of Mr. Crookes' Report.*—As this is the most systematic and scientific report yet published, we shall give a few more valuable extracts that have a broad bearing upon contagious diseases generally. Mr. Crookes' experiments have all pointed to the value of crude carbolic acid as a disinfectant, the use of which was advocated by the writer of this Summary years ago amongst a host of others.

What is understood by the term crude carbolic acid is a mixture of carbolic, cresylic, and other acids. It is an oily liquid, hardly distinguishable by an inexperienced eye from tar oil; but it should possess the property of being perfectly soluble in twice its bulk of a solution of soda containing about twelve ounces of caustic soda to the gallon. Mr. Crookes' experiments prove conclusively that carbolic acid does not retard or hasten oxidation; most of the other disinfectants do. It is therefore properly an *antiseptic*.

Some meat was hung up in the air until the odour of putrefaction was strong. It was then divided into two pieces; one was soaked for half an hour in chloride of lime solution, and was then washed and hung up again; the offensive smell had entirely gone. The other piece of meat

was soaked in a solution of carbolic acid, containing one per cent. of the acid; it was then dried and hung up. The surface of the meat was whitened, its offensive odour was not removed, though it was washed by the carbolic acid. In two days' time the bad odour had quite gone, and was replaced by a pure but faint smell of carbolic acid. In a few weeks' time the pieces of meat were examined again. The one which had been deodorized with chloride of lime now smelt as offensively as it did at first, whilst the piece which had been treated with carbolic acid had simply dried up, and had no offensive odour whatever. It was then hung up for another month and examined, but no change had taken place.

These are important experiments.

Mr. Crookes says very properly that his experiments point out in a striking manner the difference between deodorizers and antiseptics:—"Hitherto attention has been almost confined to the deodorization of gases arising from putrescence. The effect has been combated, whilst the removal of the cause has received scarcely any attention. Chloride of lime, one of the strongest of this class of deodorizers, acts, as has been shown, only on the gases of existing putrefaction, but it has no influence over the future. Carbolic acid, on the other hand, has scarcely any action on fœtid gases; but it attacks the cause which produces them, and at the same time puts the organic matter in such a state that it never re-acquires its tendency to putrefy.*

"Carbolic acid does not seem to act by coagulated albumenoid matter. Albumen was mixed with four times its bulk of water, and a one per cent. solution of pure carbolic acid was added to it. No change took place for the first few minutes, but after a little time a white cloudiness was formed, which gradually collected together into a coagulum. On separating this and exposing it freely to the air, it entirely resisted putrefactive decomposition; the solution strained from the coagulum still contained carbolic acid and uncoagulated albumen. The same experiments, repeated with cresylic acid show that that acid had even less affinity for albumen."

As regards the action of carbolic acid when injected into the system, Mr. Crookes says, when an animal is killed by this means circulation is instantly arrested, the blood is not coagulated, and no alteration either in the shape or appearance of the globules can be detected under the microscope. The only apparent change consists in the immobility of the globules. In the *Annales de Chimie* for October M. Bechamp says that creosote appears to be the agent which most strongly opposes the development of organic ferments when they are once developed. This assertion is in direct opposition to all Mr. Crookes' experiments, about the accuracy of which there can be no doubt. He says that in the presence of carbolic acid the development of embryotic life is impossible, and before its powerful influence all minute forms of animal life must inevitably perish. It may be considered as definitely proved that the vapour of carbolic acid in the atmosphere exerts a special selective power on all minute organisation possessing life.

On the injection of carbolic acid and bisulphite of soda into the blood of diseased animals, Mr. Crookes gives the following results:—"If harm were to follow the injection of carbolic acid the mischievous effects would be immediate, and that if the fluid could pass through the heart without exerting its paralyzing action on that organ, and could get into the circulation, no present ill effect need be anticipated. In every case where the carbolic acid was injected marked improvement was evident, and in some cases the animals recovered. In Mr. Crookes' experiments

he endeavoured to inject a maximum amount in a given time; a smaller amount injected at an interval of, say every two days, would probably give even more decided results. One cow that recovered bore the injection of six ounces of a solution containing 105 grains of carbolic acid. Sulphites produced more pain on injection, and the experiments did not seem so successful.

TRANSFORMATION OF RED PRUSSIAN OF POTASH INTO YELLOW.—M. Weltzien says that when we treat ferricyanide of potassium with an amalgam of sodium or potassium, it is transformed into the yellow ferricyanide of potassium.

ON THE DENSITY TEST FOR UNGUENTUM HYDRARGYRI.—Mr. G. Pile proposes, in the *American Journal of Pharmacy*, to assay, if we may use the term, mercurial ointment by its density. After describing the precautions necessary in making the experiments, he gives a table from actual trials with ointments made of various proportions of grease and mercury:—

Mercury.	Grease.	Sp. Gravity.
1	10	·981
2	10	1·065
3	10	1·147
4	10	1·229
5	10	1·311
6	10	1·393
7	10	1·471
8	10	1·548
9	10	1·625
10	10	1·700

—*British Pharmacopœia.*

ANIMAL ELECTRICITY.—Dr. Charles Radcliff constructed two electroscopes, in which one had the gold leaves charged with positive electricity. This is called the positive electroscope, and positive electricity causes increased divergence of these leaves. Negative electricity produces increased divergence of the leaves of the negative electroscope.

Dr. Radcliff obtained proof of the existence of great variations in the electricity of himself and others, at various times and under various circumstances. He has begun a series of observations with a view to ascertain the electrical condition of the human body at different times and under different circumstances as to health and disease. In the great majority of cases the electroscopic indications were those of positive electricity. The dead body exhibits no signs of electricity. As regards the electricity in living blood, the writer found as a rule decided indications of negative electricity indifferently in arterial or venous blood; now and then he found comparatively feeble signs of positive electricity. In every case where he examined blood after an interval of an hour or so from the time when it had flowed fresh from the vessels he failed to detect any sign of electricity, negative or positive. Living nerve tissues as a rule furnish electroscopic signs, sometimes positive and sometimes negative. These signs are always absent when the nerve tissues may be supposed to have lost all traces of vitality. He found also in the great majority of cases that all parts of the surface of living muscle furnish indications of the same kind of electricity, and that this electricity was sometimes positive, sometimes negative, and that these signs were invariably absent in muscle which had passed into the state of *rigor mortis*. The experiments moreover make it difficult to agree with Professor Du Bois Reymond in thinking that the longitudinal surface, natural or artificial, of the muscular fibres, and the transverse sectional surface of these fibres are electrified with different kinds of electricity. With respect to the electricity of muscular tissues, it seems to be precisely the same in character as that of the nerve tissues.

SOLUBILITY OF CARBONATE OF CALCIUM.—M. Cruse publishes some results which are only confirmatory of an experiment performed some years since by Dr. Hofmann. That experiment proved that, contrary to preconceived ideas, chalk was soluble in water without the aid of car-

* The experiments and conclusions contained in Mr. Crookes' report are completely borne out in a paper written some considerable time since by the Editor of this Summary. This paper has been in the hands of the publisher some two months, and although written in connexion with the preservation of animal food, the results contained therein are most confirmatory of the above experiments.

bonic acid. On boiling a solution of lime in carbonic acid for some considerable time, the water on cooling retains always a small quantity of carbonate in solution (.034 per litre); this solution, on filtration, does not give any precipitate with lime water. It therefore consists of carbonate of calcium, and not bicarbonate of calcium.—*Annalen der Chemie.*

PREPARATION OF A WEAK SOLUTION OF PEROXIDE OF HYDROGEN.—This preparation, which has been used for medicinal purposes, is a difficult substance to make when pure, and is very liable to change when procured. Schonbein has published a process by which a weak solution of this substance can be extemporaneously made. This solution may be prepared by shaking violently for a few seconds amalgamated granulated zinc with a little distilled water contained in a large bottle. Oxide of zinc and peroxide of hydrogen are formed, but no zinc or mercury is dissolved.

Proceedings of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 12TH, 1866.

Dr. P. BLACK, Vice-President, in the Chair.

A CASE OF PREMATURE MENSTRUATION.

By T. C. ALBUTT, M.B.,
PHYSICIAN TO THE LEEDS FEVER HOSPITAL.

THE patient, M. A. W.—, was seen in the summer of 1865, and was reported to have menstruated within the last few days. Her age was one year and six months. The child was then suffering from emaciation, weakness, quick pulse, and other symptoms of hectic fever. These symptoms passed off in a few days, and the child partially recovered her health. On examination, the anal and genital regions were found free from discharge, and quite healthy in appearance. On the following month the discharge again appeared, and after it had passed away the author found the child, as before, in a state of hectic, and still presenting a perfectly healthy appearance about the anus and pudenda. He was unfortunately unable, being absent from home for a while, to see the child during the continuance of the flow. In about a fortnight the child had again recovered some degree of health. On many occasions the author carefully examined the child for disease in other organs, and did not find anything of importance. At the third monthly period he actually saw the child in a menstruating state. The discharge appeared with curious accuracy at the month, and lasted about two days and a half. The discharge was sanguineous, and in every way resembled that of a girl at puberty, but was more scanty in quantity. A return of the hectic fever followed, and the child's life was endangered. She recovered, but only to be again prostrated by a fourth appearance; and after a fifth she died, wasted and exhausted, without any effort to rally. There were no other signs of premature puberty. A post-mortem examination could not be obtained. Among many cases of premature menstruation on record, there are two in which the menses appeared at the age of nine months, and one in which the discharge appeared at the age of two years. The first two cases are reported in the "Transactions of the Royal Medico-Chirurgical Society," vol. ii., p. 116, and in the *Lancet* for November, 1828, from Michel's Archives. The former cases were seen by Dr. Martin Wall. The third case is reported by Mr. Embling in the *Lancet*, 1848, p. 137. In these three cases obvious signs of puberty were seen in the genital organs, mammae, and elsewhere, and these signs form a great part of the interest of the cases.

In other cases of premature menstruation, exhaustion and death have occurred as in this.

CASE OF MYELOID TRANSFORMATION OF THE LUNG.

By T. C. ALBUTT, M.B.

The present perhaps unique case of complete myeloid transformation of the lung occurred under the author's care in the Leeds Infirmary: During life there were found complete dulness and stillness all over the left chest, and absence of vocal sounds and fremitus—or at least these, from the feebleness of the subject and the distance of the voice, were indefinable. The heart was seen to beat under the right nipple. Cough was almost absent, and there was no great dyspnoea. The intercostal spaces were not bulged, and the circumference of the left chest only exceeded that of the right by three-quarters of an inch. There was some degree of emaciation and of hectic fever present. The duration of the disease was uncertain, but certainly of eighteen months' standing. There was no marked cancerous cachexia of appearance, and the progress seemed to have been slow. The boy was 14 years of age. He remained in the house about eight weeks in the autumn of 1865, and, becoming more and more exhausted and short of breath, he left the hospital for home, where he died in a few weeks. Mr. Jessop performed the post-examination for the author. The whole of the left chest was found filled with solid substance, thrusting the heart out of sight on the right side, and pushing down the diaphragm to the left kidney. The solid contents were of two kinds. The upper portion which appeared on opening the chest was of a dense fibrous character, of a greenish-white colour, and presented the form of an enlarged lung. Below this, occupying the whole back of the chest, and in contact with the costal pleura, was a considerable quantity of true myeloid matter, soft and sanguineous. Both substances contained myriads of little bones, varying from the size of a pea to that of the thumb. These being densely packed in the upper and firmer mass made it almost impenetrable. The origin of the disease was probably in the chest-walls, and had thence impregnated the lung. No attachment could be found, however, nor disease of ribs or spine. The friends of the lad stated that he had been short-winded since his earliest age, and had presented some prominence of the chest for many years.

AN INQUIRY INTO THE INFLUENCE OF PREGNANCY, THE PUERPERAL STATE, AND LACTATION ON THE DEVELOPMENT AND PROGRESS OF CHRONIC DISEASE OF THE SKIN.

By BALMANNO SQUIRE, M.B., F.L.S.,

SURGEON TO THE WEST LONDON DISPENSARY FOR DISEASES OF THE SKIN.

(Communicated by WILLIAM JENNER, M.D., F.R.S.)

Mr. Squire related several cases of psoriasis (lately under his notice) in which the development and progress of the disease appeared to be influenced in a remarkable manner by pregnancy, the puerperal state, and lactation. From the data afforded by these cases he drew the following conclusions:—

1. That lactation is an exciting and sustaining cause of psoriasis.
2. That the period occupied by pregnancy and its sequel, the puerperal state, is unfavourable to the manifestation of the disease.

Why the puerperal state should exert the same influence as pregnancy on the eruption, and why the effect of lactation should be of the opposite kind, might not at first appear. The explanation, Mr. Squire thought, was to be found in the fact that the uterus, either when gravid or when undergoing the process of involution, was at its maximum of functional activity. Whereas during lactation its functions were more in a state of abeyance than at any other period of its functional life: more so than when menstruation was regularly taking place, and more so certainly than when the organ was either

gravid or undergoing involution. He arrived, therefore, at the following proposition:—That when a woman has exhibited a predisposition to psoriasis, her liability to an eruption of the disease at any time during the catamenial era will be inversely as the functional activity of the uterus at that time. In further support of this view he adduced the details of two more cases of psoriasis, which showed that the development of the disease may be connected with amenorrhœa. Of these examples the one occurred at the commencement and the other at the close of the catamenial era. In the former the first appearance of the disease coincided with the first molimen menstruationis. In the latter, the sudden and apparently premature arrest of the catamenia was promptly followed by the appearance, for the first time in the patient's life, of an eruption of psoriasis. The cases he had brought forward, it would be observed, were all of them cases of psoriasis. This was owing to his having preferred, in the first instance, following out his inquiry in one channel. He was, however, by no means prepared to say that psoriasis was the only chronic disease of the skin that exhibited the peculiarities he had described, but thought it extremely probable that further inquiry would show that other chronic diseases of the skin besides were similarly influenced by the state of the uterine functions. That pulmonary consumption might be arrested by pregnancy was well known, as well as that its course became unusually rapid shortly after delivery. But similar observations, so far as he knew, had never as yet been made on psoriasis; and it might be that there were many other instances of chronic disease, whether of the skin or of other organs, in which the control exercised by uterine influence in determining their commencement and in modifying their progress has in like manner escaped observation.

Dr. HILLIER said he could not corroborate the author's experience in reference to psoriasis. He had seen one case only of that disease in which eruption was worse during lactation. In his experience it was subject to relapse under very varying conditions. It very often became worse in the spring and when the patient appeared in robust health. Eczema, on the contrary, he had found to be often aggravated or induced by lactation, and at the climacteric period in women. Psoriasis very commonly began before puberty, and not at all frequently at the period when the catamenia ceased.

Dr. GREENHOW said that the author appeared to have overlooked the relation existing between psoriasis and the gouty constitution, and the fact that gouty ailments were liable to appear during lactation, and would disappear when lactation was over. Thus, in the cases related the connexion might be betwixt gout and psoriasis, although the appearance of the psoriasis might be directly due to the debility induced by suckling.

Dr. A. P. STEWART said that for fifteen years he had noted the frequent coincidence of psoriasis with lactation, and also of many cases with rheumatism or gout. He agreed with Dr. Greenhow that the connexion of psoriasis with gout was very strong.

Mr. BALMUNO SQUIRE was glad to find his researches supported at least in some degree by the observations of so careful and experienced an observer as Dr. Hillier. Yet he still continued to think it not unlikely that the examples he had adduced were mere coincidences. He did not bring them forward as picked cases to exemplify a fact of which he (Mr. Squire) had become previously persuaded. On the contrary, his attention had first been attracted to the subject by the history of the first of the cases he had narrated, and the remainder were given in his paper without any kind of elimination. They were simply the history, and the whole history of the subject, as it had come before him clinically during a certain period, the only qualification for the admission of a case into the series having been psoriasis plus either exaltation or suspension of the uterine functions. Mr. Squire then recalled attention to the case of the woman who, having suffered from psoriasis before her marriage and having

been subject to it since, had during her married life been five times pregnant, and on each of the five occasions had been temporarily free from psoriasis, but on those occasions only. From that case he thought the conclusion was fair that pregnancy was at all events sometimes antagonistic to psoriasis. Dr. Hillier had misapprehended him in supposing him to advance lactation as the cause of psoriasis. The tenor of his paper had, he thought, clearly indicated a presumption on his part of a predisposition to the disease in the examples he had brought forward. The object of the paper was not to show that lactation was the cause of psoriasis, but that it was an agency favourable to its development in persons in whom a predisposition to the disease existed; and that pregnancy, on the contrary, was a condition which was, so long as it lasted, unfavourable to the manifestation of the disease. In reference to Dr. Greenhow's and Dr. Stewart's remarks, Mr. Squire said that the development of psoriasis, as was well known, was usually associated with a vigorous state of the general health, and often with a state of plethora. Gout, he believed, was allowed to be often associated with the same general condition. He saw no reason, after having made inquiries specially directed to that subject, to suppose that there was any intimate connexion betwixt psoriasis and gout, and he was inclined to think that in the instances observed by Dr. Greenhow and Dr. Stewart the association of gout and psoriasis was to be considered as dependent rather upon a common predisposing cause—viz., an exalted state of the functions of assimilation—than as due to a dependence on the part of psoriasis on a gouty condition of the system.

TWO SUCCESSFUL CASES OF CÆSARIAN SECTION.

By Dr. BAEZA.

Case 1.—A woman, aged 38, had had three difficult labours, the children being all dead. In her fourth pregnancy, at term, she suddenly felt pain, and the fœtus moving outside the uterus. Severe fever followed, and on the third day the placenta was discharged. The fever lasted thirty days, attended by great pain in the abdomen. At the end of this time a large quantity of foul pus flowed from the vagina. A foreign body was now seen projecting below the umbilicus. This swelling burst; the head of a fœtus was seen in the opening. After a few days the patient herself dragged a portion of the tumour out. An incision was made in the abdomen, and the entire skeleton of a fœtus was extracted. The cavity of the cyst was washed out with warm water. The patient recovered.

Case 2.—A woman, aged 42, had had seven children. In September, 1863, she was again pregnant. She felt the child at four months, but the pregnancy continued for an unusual time. On the 10th May, 1864, when estimated at term, she felt a severe pain in the right leg which spread to the loins and hips. These increased, and great prostration ensued. At this time the cervix uteri was felt as in the non-pregnant state; a little pure blood, however, issued from the vagina. At the end of July she had renewed pains, and an offensive discharge escaped from the vagina. The pains remitted, and the abdominal tumour diminished. The 10th January, 1865, she came to the hospital. There was a then hard tumour, the size of a seven months' pregnancy. Crepitation was felt in the highest point. The general condition was that of hectic fever. An abdominal section was made on the 15th January. The bistoury struck upon a firm mass, which on section resembled the uterus. The fœtus was found in a cyst, macerated in a quantity of stinking matter, which was washed out by warm water. None of this fluid came out by the cervix uteri. The cyst had several diverticula, one of which seemed to communicate with the uterus. The cyst gradually shrank, and the woman recovered.—*Siglo Medico*, and *Brit. and For. Med.-Chir. Review*.

SCLEROSIS OF THE BRAIN AND SPINAL MARROW.

W. ZENKER of Gottingen contributes observations made by him during some months past on this subject. The microscopical investigation of sclerosed spots in the brain, made in a fresh condition, gave the following results:—Connective tissue-fibre existed in abundance, containing many interspersed nuclei, whilst no trace of brain-elements and nerve-fibres could be discovered. Moreover, amylaceous corpuscles, recognized as such by their reaction with iodine and concentrated sulphuric acid, were found scattered in great abundance and lying about in heaps in the field of vision, in size from that of a connective tissue-nucleus to that of a frog's blood-corpuscle, as round bright bodies, in which here and there a nucleus and also a concentric arrangement was distinguishable. As it seemed to be necessary to make a further investigation with finer instruments, some large sclerosed spots of the white substance of the cerebral hemisphere were hardened—a part in most highly rectified alcohol, and another part in a solution of two parts chromic acid to 1000 of water. After fourteen days the further examination was made and the following results obtained:—

1. In the chromic acid preparation, sufficiently fine sections, made with a razor, showed a fine connective tissue, consisting of fibres. These appeared to be in part arranged as a network, in the meshes of which appeared the form-elements to be mentioned later. In thicker sections there was found only an apparently finely granulated mass, in which it appeared that many fibres were cut obliquely or across. This partly net-shaped arrangement of the fibres was not probably an artificial production by the coagulating influence of the chromic acid solution upon an albuminous fluid, because, in certain spots, the fibres united into thick bundles passed away parallel among each other. The same fibres, but less easily, could be shown in the alcohol preparations. After the addition of acetic acid the fibrous arrangement disappeared altogether.

2. In the alcohol preparations, but not in those made with chromic acid, were found those larger and smaller concentric corpuscles which, in a fresh condition, the iodine sulphuric acid reaction had exhibited.

3. In the chromic acid preparation there were found, moreover, in the meshes in question, very numerous oval, somewhat flattened, or egg-shaped and incurved nuclei. There could not positively be shown around the nuclei cell-processes and cell-membrane, although in carmine preparations the appearance of spindle-shaped, star-shaped, or anastomosing cells was often very evident. This was sometimes produced by the nuclei lying embedded in the meshes of the fibrous bands crossing each other. In no way could anything but nuclei be isolated. Fine sections of the alcohol preparation, moreover, were treated with the ammoniacal carmine solution, then washed out with a saturated solution of acetic acid in distilled water and concentrated glycerine; then, again, the covering glass being frequently lifted, it was washed with water and finally the preparation examined in a glycerine solution. By this method the nuclei described were found to be dyed red.

4. Also, by the treatment just mentioned, the capillary vessels appeared as distinct strings furnished with very numerous nuclei in their coats. As to the capillary vessels themselves, many of them showed considerable fatty degeneration of their coats, which was very beautifully seen by treating the alcohol or chromic acid preparations with diluted soda solution.

5. Independently of the sclerosed parts the rest of the brain showed no essential change. Ganglia cells, however, were not unfrequently met with in the vicinity of the sclerosed spots. These were decidedly fatty degenerate, for they were almost completely untransparent, and filled with closely packed fatty granules; so also were their processes.

From all this taken together its results that, viewed

microscopically, it was a pathological new formation of a tolerably distinct fibrous connective tissue, with overgrowth of its nuclei, and of the nuclei of the capillary vessels, with a probably secondary fatty degeneration of the coats of the latter. The ganglia-cells may then have been changed by pressure of the callous connective tissue.

The microscopical examination of the spinal cord, preserved in alcohol, gave the following results:—In the cervical region, sections of the posterior columns made with a razor, treated with an acetic acid solution showed the same characteristics as did the sclerosed spots of the brain; a network of fibrous bands (here even more pronounced than in the brain); abundantly interspersed nuclei; concentric corpuscles; fatty degenerate capillaries; and in the same proportions as in the brain.

Cross sections of the lateral columns showed neither connective tissue-fibre with nuclei, nor fatty degenerate capillaries, but, on the other hand, a large number of normal nerve-fibres, in some parts single concentric, and here and there brown stellate corpuscles resembling pigment cells.—*Zeits. für Rationelle Medicin and Brit. and For. Med.-Chir. Review.*

ACCIDENTAL DEATHS FROM MECHANICAL INJURIES.

AMONGST this class of accidents those from vehicles in the streets are by far the most frequent. The deaths from railway accidents have increased this year from thirteen in the previous year to twenty-four. The greatest proportion of these deaths have occurred amongst men employed on the railways. In a majority of instances these accidents are the result of carelessness or recklessness amongst the men themselves. The accidents in the streets have increased from 39, including kicks from horses, in 1862-3, to 57, exclusive of kicks from horses, in 1864-5. The public attention has been drawn to the frequent occurrence of these cases by the Registrar-General. Above 200 fatal cases occurred in the streets of London alone in the year 1865. The deaths from street accidents present only a small proportion of the sufferings of the community from this cause. I have received from Mr. J. D. Hill, the active and intelligent resident medical officer of the Royal Free Hospital, the following summary of cases occurring in that hospital in the year 1865:—

Cases treated as out-patients	1131
" " in-patients.....	327
Deaths	31
	1489

thus showing that where one person dies from these accidents there are forty-eight persons injured. For the whole of London this gives an appalling amount of suffering, which it certainly behoves both the local and imperial government to make some effort to remove. The following are suggestions of the direction which efforts to diminish these accidents might take:—1. Regulations with regard to the rate at which vehicles should pass over recognized crossings for foot-passengers, and turning round the corners of streets. 2. More active police interference with vehicles driving at a rapid rate through any of the streets of London. 3. The erection of bridges or subways in the more frequented streets, that foot-passengers might pass without the liability to injury from vehicles. 4. The encouragement to the utmost extent of railway traffic underground, by which the streets would be relieved of their present crowded state. 5. The widening of small streets and the construction of new lateral streets leading from one great thoroughfare to another, so as to relieve the traffic of the great thoroughfares. 6. The abolition of obstructions in greatly frequented thoroughfares, such as "Temple-bar" in Fleet-street, Middle-row in Holborn, and many others. 7. The infliction of fines, or suspension of license in case of public drivers, in every case where persons are run over and either injured or killed. It

should be remembered that the money-value of the injury to life and limb in London annually cannot be much less than a quarter of a million.—*Journal of Social Science.*

ON THE TREATMENT OF WOUNDS BY VENTILATION.

In this paper, M. Bérenger-Feraud draws attention to a mode of treating wounds and ulcers described by M. Bouisson of Montpellier in the second volume of his *Tribut à la Chirurgie*, under the name of ventilation. This consists in fact in leaving small wounds exposed to the air, and in acting upon larger ones by means of the domestic bellows for a period varying from five to twenty minutes every two, three, or four hours, according to the amount of discharge and moisture that may be present. The object is to secure the formation of a crust over the surface of the wound, under which cicatrization takes place far more rapidly than when the surface is not so protected; and the applications must be sufficiently frequent and prolonged to maintain this crust of a certain thickness. When the crust acquires a degree of rigidity, however, it must be displaced and another formed; and when the discharge is very abundant, the alcoholic dressings, now so much in vogue in the Paris hospitals, should for a while precede the ventilation. The influence of this last in improving the condition of the wounds is almost immediate, a disposition to cicatrize and a diminution of the discharge soon being apparent.

This mode of treatment, according to its originator, M. Bouisson, may determine sedative, astringent, siccative, antiseptic, and tonic action; but it is by no means indicated in all kinds of wounds, and especially in those whose depth is great in proportion to their superficial extent. Thus, it is not fitted for penetrating wounds, as those of a fistulous character, or characterised by anfractuosités. Abundant suppuration is a further contra-indication, except, indeed, when this is due to a mere hyper-secretion dependent upon local or general atony or perverted nutrition, and to the lessening of which alcoholic dressings supply a useful preliminary to the employment of ventilation. In slight burns other means may be preferable, as of more convenient application; but in those of the second and third degree, arrived at the stage of a simple denuded wound, ventilation may advantageously supersede cotton and other impermeable applications. In resorting to this means for ulcers, we have to attend to the constitutional cause of these, as well as to render them by various local applications apt for cicatrization before we resort to ventilation.

Among the secondary advantages of this mode of treatment may be mentioned its simplicity, its easy applicability by the patient or his friends, its economy and its cleanliness. It substitutes a dry for a moist surface, diminishes the chances of septic decomposition, and lessens the chances of infection of the surrounding atmosphere.—*Bul. de Thérap. and Brit. and For. Med.-Chir. Rev.*

THE CHOLERA.

The cholera still extends its area of prevalence upon the Continent, and the disease has been imported into several English ports on the east coast, and has again appeared on the south coast. It is rumoured, also, that scattered cases of the malady have occurred in districts adjoining Liverpool and the Bristol Channel—localities into which the disease was earliest introduced during the present year.

On the 23rd of June a boy belonging to the Prussian steamer *Emilie*, Captain Pruss, from Stettin (where the epidemic was then prevalent), lying in the South Dock, Sunderland, was seized with cholera. The case was seen by Dr. Maling and Dr. Welford.

On the 29th of June, one of the crew of the barque *Clio*, which arrived in the Tyne off Shields from Hamburg on the same morning, was seized with cholera. He

had been attacked with diarrhœa the day previous. Violent cramps supervened on Friday; and when the patient was seen by Drs. Coward and Denham in the course of that day he was in a state of collapse. He was removed to the South Shields Workhouse Hospital, where he died early the next morning. The rest of the crew of the *Clio* were reported to be healthy, and were suffered to go on shore.

On the 28th—29th of June two fatal cases of cholera occurred on board an English ship which arrived at Goole on the 28th from Antwerp, where the disease has appeared.

Cases have also been reported in other ports on the east coast; and a fatal case occurred on the 2nd inst. on the south coast. The schooner *Messenger* from Southampton put in at Brixham on the 1st inst., the captain being ill at the time from cholera. He died next day.

There have been ugly rumours of the epidemic having reappeared at Southampton; but we lack details of the reputed cases there, as well as in the districts adjoining the Bristol Channel and Liverpool.

Cases are reported, unofficially, from the West Riding of Yorkshire.

It is clear, however, that there has been a free importation of the epidemic from infected localities of the Continent into our ports; and that it behoves the local health authorities to take active measures for the safeguard of the populations under their charge.

In Belgium, Holland, and Pomerania, the epidemic is steadily spreading, although the disease does not prevail with any great intensity.

The latest files of newspapers from the Hague give a long list of the communes in which the epidemic had appeared, and show that up to the 9th of June the attacks in them had amounted to 2410, the deaths to 1352. The following returns are also given from the commencement of the outbreak to the 22nd of June, 1866:

	Attacks.	Deaths.
Leyden ...	1021	649
The Hague ...	362	215
Delft ...	542	319
Rotterdam ...	824	503
Dordrecht ...	346	196
Gouda ...	140	73
Utrecht ...	688	382

The latest returns from Stettin show that from the 2nd to the 18th June inclusive there had been 537 cases, and 294 deaths.

The *New York Herald* of the 22nd ult. contains an account of several cases of cholera in that city.—*Lancet.*

ON THE TREATMENT OF FISTULOUS DISCHARGES DUE TO CARIES, &c., BY THE "LIQUEUR DE VILLATE."

In a former communication, in 1863, M. Notta drew attention to the value of the *Liquor de Villate* in the treatment of certain forms of obstinate fistulous discharges. Transferred from veterinary practice, in which it has been most advantageously used for more than twenty years, this substance has proved of great service, according to the testimony of MM. Notta, Nélaton, and other distinguished French surgeons. In the present paper M. Notta relates several additional cases, in order the better to distinguish the circumstances under which it can be resorted to with advantage. Those in which it has proved preëminently useful, have been examples of caries of bone, accompanied by fistulous track which have resisted various other modes of treatment. Still, it must not be indiscriminately employed here as it will succeed only in cases in which the caries is soft and vascular, and of limited extent, being of no avail when this is very extensive or sequestrated. Another class of cases which can be successfully treated are fistulæ consecutive to chronic abscess, often when iodine has been tried in vain. In several cases of tubercular fistula of the testis, M. Nélaton has effected a rapid cure by five or six injections. Even when the abscess has been of an acute character, but has eventually given rise to great detachments and obstinate fistulæ, the *Liquor* is found of equal value, several examples

of which are given by M. Notta. But any attempts that have hitherto been made to extend its employment to the seemingly analogous case of fistula in ano have so decidedly failed that there is no encouragement to repeat them.

The composition of the *Liqueur de Villate* is as follows:—Liquid subacetate of lead 30; sulphate of copper and sulphate of zinc aa 15, and white vinegar 200 parts by weight. It is essential to remember that it is suitable only when the affections reach their chronic stage; and that if employed prior to this period, in place of a salutary modificatory-inflammatory action, it may give rise to a phlegmon of a dangerous character. In suitable cases, injection of the fistulous tracks may be employed every second, third, fourth, or fifth day, according to the amount of inflammation produced, the patient then being allowed to repose awhile. In very obstinate cases, the injections may be made, as in veterinary practice, daily, and continued for months, if required. In all cases, however, they must be suspended awhile if too great inflammation be excited; and, in some cases, when the wound is not deep, or filled with fungosities, or when the caries is not easily accessible, some lint, soaked in the *Liqueur*, may be applied instead of using the injections. Generally the injections give rise to pretty severe pain, which may last for several hours, or even all day; but usually, though not always, after some days it becomes easily supportable. The first injections give rise to sharp inflammation in the fistulous tracks; but the suppuration, which is temporarily increased, soon diminishes. Small osseous fragments are often detached after injection; and M. Nélaton has several times observed membranous shreds—analogueous to the false membranes in the horse—coming away.—*Brit. and For. Med. Chir. Rev.*

LEGAL INTELLIGENCE.

PROCEEDING UNDER THE MEDICAL ACT.

AT Marlborough-street Police-court, on Saturday week, John Potter Sergeant, otherwise Crowther Smith, of No. 2, Pavement, Glasgow, described as a surgeon, and John Sutton, commonly called Dr. Sutton, of No. 36, Bloomsbury-street, dentist, were charged—Sergeant with procuring himself to be registered under the Medical Registration Act by false representation, and with attempting to do so; and Sutton with aiding and abetting.

Mr. Edward Trimmer, secretary of the Royal College of Surgeons of England, produced the certificate of birth and the schedule of the certificate of John Potter Sergeant, to whom a diploma was granted in May, 1836. No other diploma had been granted to any one named John Potter Sergeant since 1825.

Dr. Kenealy said he wished to put certain questions to show that the prosecution was not instituted by any of the respectable societies whose names had been imported into the proceedings.

The magistrate decided that the questions were irrelevant.

The witness, on cross-examination, said the Royal College of Surgeons were not the prosecutors in the case, but they took great interest in the affair. He was aware there was a *mandamus* applied for against the Medical Council on the part of the prisoner Sergeant. He had seen Mr. Imhoff, a pianoforte maker, against whom the prisoner Sergeant some time ago brought an action and obtained a verdict for £400.

The baptismal register of John Potter Sergeant, born in 1812, was put in and proved in the usual way.

Mr. John Roope, clerk to the Branch Council for England, appointed under the Medical Act, said it was his duty to assist at the registration of persons under the Act. The prisoner Sergeant brought him a document on the 6th of July.

The prisoner said he had heard his name had been removed from the Register in consequence of his connexion with the "Sutton gang."

Mr. John Turner, in the office of Mr. Clarke, Lincoln's-inn-fields, said he served both prisoners with notices to produce the diplomas, and they declined to do so.

Mr. Roope (recalled) said when Sergeant handed in the document he said he was John Potter Sergeant, and he applied for a re-registration. The prisoner pointed to the boy, and said, "There are my diplomas." The prisoner tendered the fee of £2. In January, 1860, in consequence of a notice, he altered the address from 45, King-street, Long-acre, to No. 8, Store-street. On the 19th April, 1861, a letter was sent by direction of Dr. Hawkins to the prisoner Sergeant to know if John Potter Sergeant still carried on business.

There was no answer to that letter. He produced the Register to prove that in 1859 the prisoner Sergeant was registered as living at King-street, Long-acre, and in 1861 at Store-street.

Sarah Smith said she knew John Potter Sergeant when in Leicester. He was articled to Messrs. Needham and Paget, surgeons to the Leicester Infirmary. She had seen his diploma from the College of Surgeons. He received the diploma in 1836. She also saw his diploma from the Apothecaries' Hall. She was present at his death. He did not practise; he gave private instruction to medical students. After his death she went back to Leicester, and took the diploma of the deceased with her. She had the diplomas at Swindon after she was married. In 1856 she missed the diplomas and a tin case in which they were kept. Neither of the two prisoners is the John Potter Sergeant she had known.

Mr. Ouvry, 66, Lincoln's-inn-fields, solicitor to the Council of Medical Registration, said a person, who stated his name was John Potter Sergeant, called at his office in November, 1865. He believed that person was the prisoner Sergeant. Two applications for a *mandamus* against the Council were made. The prisoner asked why the Council refused to put his name on the Register. He told them he believed the Council had reason to think he was connected with the Sutton gang. When the *mandamus* was applied for, the Council were not aware of the death of the real John Potter Sergeant.

Mr. Radford, reporter, 27, Victoria-road, knew Sutton well, and also his handwriting. He believed him signature and the affidavit produced to be in Sutton's handwriting. The letter produced he also believed to be in Sutton's handwriting.

Samuel Halley, in the service of Messrs. Clarke and Co., clothiers, No. 2, Red Lion-court, Watling-street, knew Sergeant. About six years ago Sergeant went by the name of Crowther Smith, and carried on the business of a clothier in the Hackney-road. He produced one of the prisoner's dishonoured bills: it had never been paid. In cross-examination this witness said the prisoner traded in the name of Crowther Smith. People sometimes trade in names not their own. One firm put the prisoner in the Queen's Bench, but he could not say whether the prisoner passed through the Bankruptcy Court.

Mr. Knox said, as far as the case against Sergeant was concerned, it was clearly one for the Central Criminal Court. He should, therefore, remand him without bail. The complicity of Sutton had not been fully proved, and he would remand him on bail with twenty-four hours' notice.

RATING OF CHARITABLE INSTITUTIONS.

THE recent decision of the House of Lords in the case of *Jones v. the Mersey Docks*, has settled the legal question as to the liability of charitable institutions to parochial and other taxes. Acting upon this decision, the parish of St. George, Hanover-square, has during the present year assessed St. George's Hospital to the poor-rate; and such hospital and the officers' house in connexion with it are assessed at four thousand and ninety pounds per annum, the amount of rate payable being five hundred and eighty-seven pounds eighteen shillings and ninepence. The vice-president, treasurers, and governors of the hospital presented, by Mr. Abel Smith, on the 13th inst., a petition against this assessment. They describe the position of the hospital in respect to its support by voluntary contributions; state that the annual subscriptions are insufficient to meet the current expenses; that it has been necessary of late to sell capital from time to time derived from legacies bequeathed to the said hospital; and that the deficiency of income which has been so met by sale of capital has amounted on an average of the last seven years to about four thousand pounds per annum. The petitioners conclude by submitting "that if St. George's Hospital be rated to the poor, the usefulness and benevolent objects of the institution will be seriously affected, and the payment of the large annual sum demanded for poor-rate will probably necessitate a curtailment of the number of patients annually relieved at St. George's Hospital."

St. George's Hospital offers a very strong illustration of the impolicy and injustice of rating charitable institutions to the poor; but no doubt there are many such cases, and it is the manifest duty of those interested to petition against a regulation so disastrous to their welfare.—*Lancet*.

Reviews.

SURGICAL APPLIANCES AND MINOR OPERATIVE SURGERY. By THOMAS ANNANDALE, F.R.C.S., &c. Edinburgh: Maclachlan and Stewart.

THIS little work is one which is extremely well calculated to be of use to the student or junior surgeon. It is profusely illustrated with numerous figures of the instruments and apparatus required, as well as with examples of the various modes of applying splints, bandages, &c.; most of these illustrations appear to be original, and they are all well and carefully done. The position its author has acquired as a surgeon, and the reputation he has already gained by his writings, are a sufficient guarantee that the surgery of this work is quite abreast of the day. At the same time, there are in it several little misprints, such as *Lotio nigrum*, &c., which might give occasion for cavilling, and which ought certainly to have been avoided; for in these days when so much is expected from students, their teachers cannot be too carefully accurate in what they say, and still more in what they print for their behoof.

There are two other points to which we would like to direct Mr. Annandale's attention—the first of these is in regard to the treatment of erysipelas, in which he recommends, after the employment of saline diaphoretics, the administration of "the muriate of iron in doses of twenty or thirty drops three times a day." Now we protest against this being considered a proper mode of administering this most valuable remedy, it is precisely in this way—from mal-administration—that useful remedies get despised and fall into desuetude; given in such doses and in such a manner, tincture of the muriate of iron is absolutely useless as a remedy for erysipelas, to act as such, it must be given early before these structural changes have commenced which cannot be checked but only promoted and guided to a close, while sixty or ninety drops a day are a mere mockery. To check erysipelas the system must be thoroughly saturated with the iron, and in severe cases from an ounce and a half to two ounces a day will be required (*vide* Holmes's "System of Surgery"), from 720 to 960 minims must be given in divided doses during the twenty-four hours, at regular intervals during the day and night; and if begun early and given in this way, we venture to say that it can and will produce effects to which Mr. Annandale seems yet a stranger, and which will certainly astonish him when first he sees them.

The second matter to which we would direct attention is the mode recommended by him for the collection and preservation of vaccine lymph; for this purpose he states that, "having filled the tube about half full, both its ends ought to be sealed up with a drop of sealing wax" (p. 211). The italics are ours, and we feel safe in saying that such a procedure has not hitherto been taught for the last thirty years at least, while we can assure him that it is no novelty, and is far from being an improvement on the mode of hermetically sealing the tubes recommended by his fellow-townsmen Dr. Husband. We regret, also, to find that in treating of fractures of the radius, he has omitted all notice of the admirable apparatus recommended by Dr. Gordon of Belfast for the treatment of fractures of its lower third, which is certainly an improvement upon all previous methods, nor has he even alluded to Dr. Heron Watson's useful modification of this apparatus referred to at page 400 of our number for the 18th of April last.

THE CONVOLUTIONS OF THE HUMAN CEREBRUM TOPOGRAPHICALLY CONSIDERED. By WILLIAM TURNER, M.B. Lond., F.R.S.E. Edinburgh: Maclachlan and Stewart. Pp. 28.

MR. TURNER is well known as a most able and painstaking physiological anatomist, his writings on the fossil skull controversy have made his name well known in regard to the conformation of the cranium, and his present *brochure* is calculated to increase his reputation in connexion with its contents. The difficulties experienced by morbid cerebral anatomists in giving accurate descriptions of the seat of morbid products, and the consequent almost impossibility of generalizing the results obtained from the examination of a large number of diseased brains viewed in connexion with their clinical histories, because of the absence of all guarantee that even in apparently the most similar cases the lesions could be properly referred to precisely the same parts of the brain, have necessitated those precise morphological investigations of the cerebral convolutions, which, within the last few years, "have led to the revival in Paris of discussions, in which the doctrine of Gall and his disciples—that the brain is not one, but consists of many, organs—has been supported by new arguments, and the opinion has been expressed that the primary convolutions, at least, are both morphologically and physiologically distinct organs." The observations of M. Paul Broca, in regard to aphasia (loss of the cerebral faculty of speech) and its connexion with a lesion of the posterior third of the inferior left frontal gyrus, along with several similar cases recorded by Dr. Sanders, Dr. Hughlings Jackson, &c., pointing apparently to some connexion subsisting between the grey matter of the island of Reil and adjacent frontal gyrus, and the faculty of spoken language, have "put this aspect of the subject into that stage that, to use the words of Dr. Sanders, 'it requires and invites fresh investigation.'" In order, however, to render this inquiry fruitful, it is absolutely necessary that those engaged in it should have the means of accurately referring the morbid lesions discovered to well-defined cerebral localities, and the topographical maps of the principal and annectent gyri supplied by Mr. Turner in this pamphlet will be found perfectly indispensable for all who are engaged in such inquiries. One of the most remarkable circumstances mentioned by Mr. Turner is, that in the brains of men distinguished for the extent of their attainments in various departments of knowledge, the surface of the cerebrum assumes an unusually complex appearance from the development of secondary gyri, as if in them we had not only an increased quantity of the grey matter—the supposed organ of mind—but also a more elaborate connexion of it with the white matter—the means of connexion of each mental organ with the others, as well as the channel of its communication with the external world—as if the manysidedness of the mind of a man of genius were not a mere figure of speech, but an actual truth dependent on his physical conformation, all this pointing to a yet undeveloped phase of cerebral anatomy of the utmost interest both to the physiologist and the psychologist.

ON RAILWAY AND OTHER INJURIES OF THE NERVOUS SYSTEM. By JOHN ERICHSEN, Professor of Surgery and of Clinical Surgery in University College, Examiner in Surgery to the University of London, &c. Pp. 144. London: Walton and Maberly. 1866.

The subject treated by Mr. Erichsen in this volume is one

of very great importance at the present time, when, in consequence of the enormous extent of the railway system, accidents on the lines are of frequent occurrence, and, as a consequence, actions for compensation are often brought against railway companies. In these actions it necessarily happens that medical evidence is sought on both sides, one party endeavouring to represent the condition of the sufferer in as serious a light as possible, both with regard to his present state and his future chances of health, and the other side exhibiting the reverse of the picture. Hence it happens, as all readers of the newspapers well know, that in such cases there is almost always a conflict of medical testimony, which is anything but creditable to our profession in the eyes of the public.

Such being the case, Mr. Erichsen has done good service by laying down in a condensed form, and in the shape of a short series of lectures, the principles on which an accurate judgment may be formed by medical men when they are consulted in cases of railway accidents and other injuries to the nervous system. For railway accidents, as Mr. Erichsen truly observes, do not differ essentially from other accidents to which mankind is liable, and many instances exactly analogous in their results to modern railway injuries have happened and have been recorded many years before railways were introduced. But still it is evident that the shock of ordinary accidents is very different in degree from that which occurs from railway injuries, the latter being necessarily more serious, from the rapidity of the movement of the train, the suddenness of the arrest of momentum in the person injured, and the depression of mind to which the sufferers are liable.

In discussing the particulars of these injuries, Mr. Erichsen purposely omits the consideration of such accidents as are attended by appreciable lesions, because in the case of loss of a limb, for instance, the effects are palpable to every capacity, and their reality admits of no doubt. But such is not the case in the instances where, although the sufferer exhibits no visible loss of limb or mutilation of structure, there is some latent mischief in the spinal cord or the base of the brain, which may render life burdensome or may prematurely terminate its duration. How the shock or jar of a railway accident directly influences the functions of the spinal cord, it is impossible accurately to determine, and Mr. Erichsen aptly compares the results which often ensue to the effect produced by a heavy blow of a hammer on a magnet, whereby the magnetic force, by some unascertained physical law, is jarred, shaken, or expelled out of the iron. So it is reasonable to suppose may the nervous force be so disturbed in the spinal cord by a railway accident that the animal functions may be at once impaired, although no visible lesion may be perceptible; and what is more, experience has shown that these primary functional effects may be followed by others of a structural character, and indicated by inflammation of the membranes of the spinal cord, or by disease of the cord itself. It is remarkable, too, that an appreciable injury of a limb, as for instance a fracture or a dislocation, is less likely to be attended by serious symptoms referable to the spinal cord, than when concussion is the only symptom and the limbs are sound. "It would appear," says Mr. Erichsen, "as if the violence of the shock expended itself in the production of the fracture or the dislocation, and that a jar of the more delicate structures is thus avoided."

After describing in succession the effects of severe blows on the spine, the concussion sometimes following slight injuries of the spine, the concussion of the spine resulting from general shock, and the effects of twists and wrenches of the spine, Mr. Erichsen discusses the very interesting questions of the symptoms and pathology of spinal concussion, and the diagnosis, prognosis, and treatment of this affection. The

diagnosis is in general not difficult, the principal diseases with which it may perhaps be confounded being principally rheumatism and hysteria, but the prognosis, as is well known, is very often the subject of doubt and even of controversy. Altogether, Mr. Erichsen thinks that the results of spinal concussion are more serious than is generally supposed, and he relates a number of cases in which the patients were most seriously damaged for many years after the accident, or in which no recovery took place at all, and where post-mortem examination showed the existence of serious myelitic or meningeal lesions.

Our limits prevent us from entering into a detailed analysis of Mr. Erichsen's very useful and instructive book, and we must conclude the present brief notice by remarking that its appearance is now particularly opportune, when definite opinions are required to be formed as to the nature and prognosis of railway injuries. It will serve as a most useful and trustworthy guide to the profession in general, many of whom may be consulted in such cases, and it will no doubt take its place as a text-book on the subject of which it treats.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 11, 1866.

THE RECENT ELECTION AT THE COLLEGE OF SURGEONS OF ENGLAND.

As we anticipated in our article of last week, the annual meeting of the Fellows of the College of Surgeons of England has terminated in the displacement of Mr. LUKE and the election of Mr. CHARLES HAWKINS in his stead. We repeat our opinion, that the contest was one only of principle, for on personal grounds no fault could be found with Mr. LUKE, and the election of Mr. CHARLES HAWKINS can only be interpreted as expressing the wish of the Fellows to break through that conventional system which has so often, on former occasions, frustrated the very objects for which the new Charters of the College were designed.

The candidates for seats in the Council were four in number (Mr. SPENCER SMITH having retired from the contest some days before the election)—namely, Mr. LUKE and Mr. HILTON, who were previously members of the Council, Mr. ERASMUS WILSON, and Mr. CHARLES HAWKINS. Mr. HILTON, being one of the Vice-Presidents of the College, and having had as yet but a very short tenure of office, was re-elected by a large majority; Mr. CHARLES HAWKINS came next; Mr. LUKE third, though at a very long interval; and Mr. ERASMUS WILSON last. Of the latter gentleman we think it only right to state that his election would have done no discredit to the College, for although he has adopted a speciality for his line of practice, he is a very distinguished anatomist, as his well-known works abundantly testify; and if it had happened to him to become an Examiner in the course of years, the *personnel* of the Examining Board would have been strengthened by his acquisition.

But we may remark that, under the operation of the new Charters of the College, there is nothing in future to prevent the election of Mr. ERASMUS WILSON, or of other gentlemen of similar attainments, to a seat at the Examining Board. In fact, the plan of electing Examiners from the Council by seniority, as is done at present, and allowing them to retain office in perpetuity, is a most mischievous arrangement, and constitutes one of the worst features in the practical working of the College. The office of Examiner is one that ought not to be looked forward to at the termination of a professional career, but should be held by men in the meridian of their faculties, and relinquished as age advances. Nor ought the Examiners to be members of the Council, because in that case the electors and the elected are virtually the same body, and there is no fair principle of selection available in filling the appointment.

Now, the obvious meaning of the new Charters granted to the College was to abolish the monopolies which it has too long cherished and perpetuated, and, by the infusion of new blood both into the Council Board and the Examining Board, to keep it on a level with the spirit of the age. The spirit of these Charters, however, has been, until recently, completely contravened, although the letter has been obeyed; and while power has been given to the Council to remove Examiners from time to time, that power has never been yet exercised, and the same persons are re-elected as a matter of course.

It is understood that Mr. CHARLES HAWKINS represents the views of those who desire that the objects of the Charters should be carried out both in the spirit and the letter, and that as he himself cherishes no aspirations to the post of Examiner he will endeavour, as far as it lies in his power, to dissociate the Examining Board from the Council. An important step, or rather two important steps have been already taken in this direction by the non-election of Mr. CÆSAR HAWKINS three years ago, and of Mr. LUKE last week. They are both Examiners, and they continue to hold that position, but they are no longer members of the Council, and have therefore no further power to vote for their own re-election. It remains to be seen whether the recent introduction of new members into the Council will be attended with any further changes in the proceedings of that body, and whether the obvious policy of the Fellows at large will be followed up by the liberal and enlightened views in the Council room.

It is almost proverbial that reformers out of office and reformers in office are very different persons, and that the atmosphere of routine and the enjoyment of the sweets of place have a wonderful influence in changing people's views, but still we cannot but believe that in proportion as the party of progress becomes augmented by the annual new elections by the Fellows, the influence of liberal and enlightened views will at last prevail, although perhaps several years must yet elapse before such a desirable consummation can be effected.

THE LOTHIANS MEDICAL ASSOCIATION.

It will be observed from a paragraph, under the head of "News of the Week," that on Wednesday last the medical practitioners of the villages and country districts around Edinburgh met and resolved to form themselves into an Association for the protection of the interests of country doctors. And in thus resolving we congratulate them on taking a step which, in our opinion, should have been taken long ago. We never could possibly see why medical men should not manage the commercial part of their profession on commercial principles; nor can we understand why they should be so modest in regard to matters of a pecuniary nature.

Why should the working man who is in the receipt of a good wage, and who never for one moment would think of leaving a district without first settling his bill with the grocer or baker, so often go off without discharging the same duty to his Doctor? Simply, we believe, because he knows that after he has left the Doctor will not trouble him any more; and he no doubt believes, too, that what is not worth asking for can hardly be of any great value! And it is the fault of medical men themselves that so many of the working classes in this country entertain and act upon such notions as these. By the carelessness and indifference of our profession in regard to money matters patients have been systematically trained to look upon services which entail a vast amount of labour and anxiety upon the practitioner as a thing of very small account and trifling value, and the sooner they unlearn the lessons they have been taught the better for themselves and for us.

Are country medical men so well to do, so opulent, that they can affect to despise money, and bestow their skill, and time, and energy upon the public without remuneration? Can they alone, of all other professional men in these kingdoms, afford to give their services gratuitously to those who are quite able, but most unwilling, to pay? Well, really, were we to judge simply from the manner in which so many of our brethren act, we would be constrained to answer these queries in the affirmative. But unfortunately we know that such a reply would be erroneous; we know that the expenses of working a country practice in many cases absorb nearly all the income; and we are also aware that many country doctors, instead of living in affluence, have the greatest difficulty in getting the two ends to meet. Why, then, should they lose accounts, which, but the exercise or better business habits, and the existence of a better organisation amongst themselves, might, in most instances, be easily recovered. At the meeting on Wednesday, the Chairman, speaking of his own practice, declared that every year he lost between £50 and £100, on account [against parties who were well able but unwilling to settle with him; and we believe that most provincial practitioners could tell a similar tale. In order to prevent such losses various suggestions were made. It was advised for instance, that at each half-

yearly term the Doctor should send in his account for attendance on the farm-servants to their masters, who would then deduct the amount from the wages. This proposal we think is a good one, and we understand that in some districts in Scotland the plan is already in operation. We think that in the great majority of instances no difficulty would be encountered in carrying out this system; for, generally speaking, farmers are desirous that all honourable debts incurred by their servants should be honestly paid. Then, again, to put a check on a custom which prevails to a very large extent amongst country people, the disgraceful practice of leaving one district without paying the Doctor, and carrying out the same tactics in another; it was proposed that something like a black-list should be instituted, from which members of the Association could readily learn whether any new-comers to his neighbourhood were defaulters or no, and might act accordingly, refusing to open a new account till the old score was cleared off. This is also a very feasible plan, and if medical men would only put themselves to the trouble of seeing that the list is correctly kept, we can see no reason whatever why such a proposal should not be carried into effect.

Of course, it is understood that these regulations apply only to that class of patients who are in a position to pay but don't choose to do so; and we entirely concur in the sentiments expressed by the Chairman of the meeting, who said "that in no case should the rules of the society be allowed to come into collision with the claims of humanity." Most certainly not; and amongst that large class of patients who, from their poverty and humble positions do not come within the operations of the Association's regulations, there is still left a field wide enough for the exercise of that noble charity and large-hearted liberality which have, in all ages, characterised the members of the medical profession. We wish the Lothians Medical Association all prosperity, and would urge every country practitioner in the neighbourhood of the metropolis to enrol himself at once as a member.

QUACKS AND THEIR VILE PUBLICATIONS.

THE following letter, which appeared in a daily contemporary, is here given as one well worthy of the attention of the medical profession:—

"TO THE EDITOR OF THE IRISH TIMES.

"SIR,—As your valuable journal has always advocated the interests and welfare of humanity, permit me to ask through its medium why the authorities permit the wholesale circulation of these vile and pernicious publications throughout our city—forced as they are daily in our public thoroughfares upon the young, in order that they may be ensnared into the 'compounding shops,' and there drugged in such a way as either to deprive them of their physical or mental powers. This, Sir, is no exaggeration—no mere abstract statement, for I have just seen a young lad, who, though perfectly sound in health, imagined, after reading one of these insidious productions, that every symptom of health was a sign of disease, so artfully are their books designed to their work of destruction. He went to the physician named in the little book, and owing to the advice he there received, and the dose he was obliged to swallow in that quack establishment, which are like pest-houses rising throughout our

city, has been for the past month perfectly insane, his mind wandering, his intellect deranged. The public have a right to insist upon this nuisance being abated, for the police have the power to seize those vile publications, and prosecute the vendors or distributors of them. If they still neglect this duty, which I think is due to humanity, I trust our new Attorney-General will direct his special attention to this very important matter, and weed out all impostors; but if he continue to pursue the principles of 'non-intervention' with regard to those 'quacks' who prey upon the credulity and weakness of our youth for their own aggrandizement, I hope he will be able to give a good reason for doing so when asked for it in the House of Commons by our city members. Surely, if the law, as it now stands, is not sufficiently strong to protect the public from every species of poisoning and physical and mental havoc, the sooner it is made so the better for the minds and bodies of all her Majesty's subjects. The attention of every qualified medical practitioner in our country should be specially directed to this crying evil until quacks and their vile publications are rooted out of our midst. Your valuable and powerful aid, Sir, in this matter will confer upon the public a great boon.—I am, Sir, your faithful servant,

"A PRESERVER OF REASON.

"Dublin, June 30th, 1866."

P.S.—If an anti-quackery association be formed my subscription is ready.

The most practical way of dealing with the very great evil alluded to in the foregoing correspondence, would be to form a committee of medical and lay gentlemen, who would coöperate to devise the best means of abating the system of quackery, now so glaringly carried on in our city, and we have reason to believe that the writer of the above letter would give such a committee the aid of his valuable services. We would be happy to receive the names of gentlemen who would be willing to form such a committee, and we can assure them that if they are determined, even now at the eleventh hour, to act in this momentous matter, the authorities and the public generally will not be slow to give them their cordial assistance. It is a duty which the qualified medical practitioner owes to himself, his family, and the public generally, that he should aid as best he can in uprooting this pernicious system of quackery out of the land.

SOME REMARKS

ADDRESSED TO THE

STUDENTS OF MERCER'S HOSPITAL,

ESPECIALLY APPLICABLE TO

CANDIDATES FOR THE PUBLIC SERVICES.

By Dr. MOORE.

As I see around me at least a score of students who, before many weeks have elapsed, will be fully qualified to enter the public services, it may not be out of place if I take this opportunity of briefly setting before you the present *critical* condition of the Army and Navy Medical services, and how far your ulterior prospects may be affected by the line of conduct you, at least for the present, pursue towards these departments. Many of you are no doubt aware that a Commission was appointed about eighteen months ago to report on the medical service of the army and navy, with a view to remedy some grievances which have long been complained of. The report of this Commission, although not long, deals with military status, rank, pay, promotion, and all other questions which could come fairly under its consideration, its purpose professedly being to encourage a larger number of the most eligible class of candidates, so as to render the competitive examinations really worthy of the name, and such as were

contemplated upon its establishment. Now, one of the first difficulties this Commission had to meet with was the subject of "slowness of promotion for junior officers;" in short, what plan the committee could devise to induce men to place their names at the foot of a list of some 700 or 800 assistant-surgeons. This has been met by giving the assistant-surgeon better pay, and after ten years' service giving him a pecuniary equivalent equal to the present pay of the full surgeon; after fifteen years, 17s. 6d., instead of the present 13s. This scale of pay seems reasonable enough, but all increase of pay for assistant-surgeons ceases after fifteen years. You will readily see that a service never can command highly educated men where they have almost a certainty of spending a great part of their lives in a subordinate rank, whilst in the Navy the promotion has been, and is quicker, and the Indian Medical Department fixes twelve years as the time for promotion. Another method of accelerating promotion is proposed—viz., an earlier permissive retirement; a retirement after twenty years' full pay service; the retiring allowance to be exactly the half of the pay which the medical officer may be in receipt of at the time his twenty years are up. Now in the case of a man joining at present, and at the present rate of promotion, he would be an assistant-surgeon twenty years hence, his pay 17s. 6d. per day, and his retiring allowance only 8s. 9d.

Surgeon-Majors retiring at fifty-five years of age (compulsorily) are recommended to be given a retirement of £1 per day, or about 1s. 6d. a day more than at present if they are compelled by their age to retire, instead of going voluntarily after twenty-five years' service. As regards the recommendations as to rank, position at mixed boards, and social distinctions, they are more definitely set forth; but, as I have frequently told you, the latter cannot be regulated by warrants, blue-books, or such like documents, they are and must be very much of your own making.

And now as to the Navy. To compensate the naval surgeon for loss of time by his being placed on half-pay and unable to obtain employment, it is recommended that the surgeons' and staff-surgeons' full-pay should increase by periods of four years, instead of five as at present; and with respect to cabins, about which we have heard so much, that whilst the requirements of the service render it necessary that the senior executive officer and the staff commander or master should have the cabins placed most advantageously for their special duties, medical officers should after them have cabins more in accordance with their relative rank in the service, and that cabins for assistant-surgeons should be specially ordered, to prevent future difficulties or neglect of the existing Admiralty order. Hitherto the contrast between the two services, as regards rank, pay, and allowances, was, to say the least of it, unfair; but, under these recommendations, the promotion in the naval medical service will be quicker than that of the army, whilst the pay for juniors will be quite as liberal.

Well, on the whole, whilst these suggestions are not all that could be desired, still they are a step in the right direction, and should be taken as an instalment; but what is the fact? This report was issued in February, and up till the present it remains a dead letter, and when questions have been asked from time to time as to carrying out its recommendations, the answers have been somewhat in this wise—"That the War Office had not

communicated with the Admiralty, and that the latter department in its turn had not consulted with the Treasury, and *vice versa*." Well, the way at once firmly, temperately, and self-respectfully to give the quietus to such replies is simply by giving these respective departments a "wide berth," as the sailors say, for the next twelve months, when I am satisfied all these improvements will be carried out; for so long as they can obtain candidates, experience has shown us no concessions will be made. This can be no hardship to any of you, as the emigration service, the mercantile marine, home and colonial appointments, are open to you. For the past *six* months I believe the naval service has not had *as* many candidates, and if the same negative treatment is applied to the War Office the cure will be perfected. By this course you will simultaneously and materially serve your professional brethren already in harness, those who hereafter may be disposed to adopt it, and the military service of our common country.

THE QUEEN'S UNIVERSITY.

OUR readers will have perceived that a new Charter has been granted to this body which confers similar powers to those of the London University—namely, that of admitting to Arts Degrees without study in Colleges, and to Medical Degrees, if lectures are attended in any recognized school. At the same time the Senate is to be increased to 24, one place to be filled by Convocation. Of the 23 present members but 3 are medical men, while in the analogous body—London University—of the 83 members of Senate, 15 belong to our profession. For this reason, among others, we are gratified to learn that Dr. MAPOTHER is to be proposed for the Senate in Convocation as one of the most distinguished Graduates of the University. All Doctors of Medicine, Masters of Arts, and Bachelors of Arts of two years' standing are entitled to vote. Application should be made at once to the Secretary of the Queen's University, Dublin Castle, as the meeting of Convocation will take place in a few days.

Notes on Current Topics.

Dr. BURROWS has been appointed by the Home Secretary a member of the Senate of the University of London. No appointment could have been more satisfactory to the profession.

The Cattle Plague Commissioners have presented to the Royal College of Physicians of London the very valuable collection of original drawings illustrating the pathology of the cattle plague, from which the illustrations to the recent parliamentary report were copied.

It is observed with much satisfaction that Sir W. Fergusson and Mr. Paget, who had been in attendance on the Speaker of the House of Commons during his recent illness, were present at the last unofficial dinner.

A case of Cæsarian section has occurred in Liverpool under the care of Dr. Grimsdale. The latest accounts report that after nearly three weeks the patient is in a fair way of recovery.

Mr. Alexander Ure, late surgeon of St. Mary's Hospital, London, died on the 15th inst. He appears never to have recovered from a serious fall which he had from a horse, about three years ago. Mr. Haynes Walton will succeed him as surgeon to St. Mary's Hospital.

MR. GRIFFIN AND POOR-LAW REFORM.

THE meeting held in London on Thursday last in honour of Mr. GRIFFIN, and the presentation of a testimonial to him by his brethren of the Poor-law service and others, are only the just rewards of years of disinterested labour in the promotion of Poor-law Medical Reform. Eleven years ago Mr. GRIFFIN commenced his work amidst every kind of opposition and discouragement, and ever since he has consistently, incessantly, and indefatigably, pursued his one great object—namely, to improve the condition of the Poor-law Medical Officers. We ourselves know how arduously he has toiled in this service amidst difficulties sufficient to appal any one unless possessed of the indomitable energy which has characterised all Mr. GRIFFIN's proceedings, and which has enabled him to encounter successfully the red-tapism of the Poor-law Board at Whitehall, and even the opposition of the House of Commons. Year after year has the topic of Poor-law Medical Reform been forced upon the attention of the reluctant Legislature by Mr. GRIFFIN's representations, and although the victory is not yet achieved, much has been done at least to enlighten the public mind on the subject. Of late the revelations made into the condition of the Metropolitan Workhouses have given a fresh impetus to the cause advocated by Mr. GRIFFIN, and he may enjoy the proud satisfaction of feeling that his labours have not been in vain.

DISPENSARIES AS SCHOOLS OF MEDICINE.

THERE can be no doubt that our Edinburgh Dispensaries have capabilities for being made schools of practical medicine hardly if at all inferior to the Royal Infirmary, while they also possess some superior advantages which are peculiarly their own. There is, however, just as little doubt that as at present worked they are of comparatively little use to the student, while to the practitioner—the medical officer—they are little more than a mere waste of time, and the patient is only benefited, as it were, on the average, that is, treated on the wholesale principle—as he must be—he is only benefited in proportion to the closeness with which his case approaches that happy medium of the disease—whatever it may be—for which the prescription supplied him has been devised. It is a fortunate thing for the patient, and a consolatory thing for the physician, that curable diseases get well under various treatments, while any little soothing prescription whereon to pin their faith is preferable to that utter and hopeless neglect to which such patients would, failing these dispensaries, be exposed. But however much the student may be impressed with the apparent skill of the necessarily rapid diagnosis, or with the apparent suitability of the prescription which he laboriously writes to dictation, he gains but little information, for there is no time to explain the steps by which the diagnosis is arrived at, nor the ends intended to be gained by the pharmaceutical combinations prescribed, and what little he does learn is but the lowest and least useful

form of medical knowledge, the parrot-like routine of this prescription for bronchitis, that for pleurisy, and something else for hooping-cough. All this is bad both for patient, for teacher, and for student; but with a mob of patients, averaging from twenty to fifty, to be seen in at most two hours there is no help for it, no hope of improvement. Yet what a vast field of study is here wasted, what ample means of tuition thrown away! To utilize these we want, in the first place, double the number of medical officers, so as to give each one time to teach his students, and explain the steps of his diagnosis, and the reasons for his treatment; we want also in each reception-room a cupboard containing all the modern appliances for aiding diagnosis, a microscope, a laryngoscope, &c., and with all the usual means of making local applications—sponges and solutions for the larynx, &c.—always at hand. These ought to be supplied from the funds of the dispensary; many of the medical officers would even be glad to supply them themselves, were there any place to keep them, any prospect of using them profitably.

These alterations and improvements alone would enable the students to be taught the arts of diagnosis and of prescription on a far larger scale than is possible in the Infirmary, while the results of treatment would be learned from the out-door cases under their own immediate care, or, if need be, in certain cases, by following to their own homes such of the casual patients who might not return sufficiently often. When the students once ascertained that they could be thus thoroughly grounded in practical medicine at the dispensaries, there would be no lack of them, and any little expenditure would be amply repaid by an increase of students' fees, as well as by the increased usefulness of the dispensaries and the fame which they would acquire as schools of medicine.

As a school of pathology, and as a place to learn the diagnosis and treatment of the rarer and more severe forms of disease, the Royal Infirmary would still remain unrivalled. But the greater bulk of the cases in ordinary medical practice are neither rare nor severe, and as a rule examples of them are never seen within the walls of the Infirmary. These two schools would therefore not interfere, their interests would never clash, the one would worthily supplement the other, and both would combine to build up the student of medicine into the practical physician, skilled in the diagnosis of the more obscure forms of disease, and yet not unacquainted with those slighter ones which will in after life become more peculiarly his daily care. We should not, however, wish the student to infer that amongst dispensary patients we have no rare or obscure forms of disease; on the contrary, they occur in a proportion considerably above what they do in ordinary practice, though inferior of course to what they do in the Infirmary, whither it is chiefly cases selected for their obscurity and rarity that are sent, though for obvious reasons of course their true nature is more readily, and in many cases more certainly, elucidated in the one case than in the other.

Correspondence.

THE TREATMENT OF DELIRIUM TREMENS.

MANY and various theories have been propounded during the last few years as to the treatment of delirium tremens, with arguments appertaining thereto, good, bad, and indifferent. Opium, digitalis, purgatives, with the presence or absence of stimulants, have all had their advocates, and varied results have followed these various plans of treatment. The pages of a contemporary have lately been occupied with an exchange of somewhat caustic correspondence relative to this important subject, the antagonists representing severally a London and an Edinburgh School of Medicine. The physiology of this disease, with its causes and consequences, cannot now be much a matter of dispute; but it is very advisable that we should arrive at some just and definite conclusion as to the *rationale* of treatment, and I cannot but think that we ought now to class delirium tremens among the controllable diseases. That it has not hitherto been so the statistics of our hospitals fully prove, and I am thereby induced to state simply the outlines of a course pursued at this institution during the past two years with its results, and so leave the reader to draw his own inferences and conclusions. It is hardly necessary to state that sailors are specially prone to this disease, suffer from repeated attacks, and these mostly of a severe form. An incorrigible offender (who generally sails in one of our smartest Blackwall ships) was admitted here some two months ago for the fifth time, and, as it seemed likely, for the last. By comparing the annual admissions on board this ship for this disease with those of St. Bartholomew's Hospital, it is found that the *Dreadnought* list exceeds that of the above hospital by about eighty per cent., so that in the matter of numbers it is fairly presumable that this institution has the largest annual score of delirium tremens in London. Until about two years ago the treatment followed on the medical deck of this ship was identical with that carried on in the great majority of the other metropolitan hospitals. Opium and stimulants were the staple articles supplied, both being given, as a general rule, in very large doses. On looking back to the statistics of former years, I find that the mortality here was about equal to that which it had obtained at St. Bartholomew's Hospital. The present plan consists, as to therapeutics, in the administration of a black draught on entry and a lavender placebo, no other drug of any sort or kind being given either at the outset or during the progress of the case. No stimulants are ordered. The patient is supplied with strong beef-tea, milk, and water *ad libitum*, and solid food is given as soon as the stomach is able to bear it. A little forcible restraint is practised as is consistent with safety.

The average duration of cases here is from eight to eleven days, very few extending over a fortnight. During the past three years sixty-four cases have been admitted, but of this number two deaths have occurred, one of these being complicated with dysentery and hepatic abscess. Many of these cases were very severe, and the quantities of liquor consumed to produce such undesirable results appear to landmen almost incredible. The notes are before me of a case in which the subject thereof was then suffering from a seventh attack of "the horrors." His average daily allowance during the week previous to admission had consisted of from ten to twelve glasses of rum, one and a half to two gallons of beer, and a few "tots" of brandy to vary the proceedings. A sum of twenty pounds was expended in three or four days in this and other species of debauchery. The two cases following state that from thirty to forty glasses of rum or brandy was the daily quantum imbibed. These are by no means exaggerated samples of the cases

received into this hospital, and I think it must be allowed that with such antecedents, a mortality of three per cent. is by no means large. The sum of cases here recorded appears sufficiently numerous upon which to form an opinion as to the propriety and value of the treatment adopted, and I am bound to say that we had viewed this plan in an eminently favourable light. The patients are, of course, for some hours after admission very noisy and troublesome. Constant watching is required, and it may be fairly discussed whether by hypodermal injections of morphia this noisy stage might not be mitigated and shortened, or even entirely avoided. Such a plan is, I believe, practised with success at Bethlem and other asylums for the insane. During the last month three patients have been treated here with hypodermal injections, containing from one-third to one and a half grains of morphia. A general and immediate quietude followed, and the annoying stage of yells and violence was thereby avoided. It will be a pleasure to furnish, at a future period, more ample proofs as to the efficacy of this last aid to treatment. Meanwhile, it is well worthy of consideration whether, in the administration of opium and other narcotics, we are not meddling with and muddling the efforts of nature to eliminate a poison from the system, and whether, too, by giving stimulants, we are not adding to the bulk of a poison that it is our desire entirely to remove. Statistics in medicine should be superlatively precise or they are worse than useless, as leading inevitably to erroneous results. At this hospital quality as well as quantity of cases of delirium tremens are entered, and the statistics of these cases, simple as they are, have been gathered carefully. The results should afford some proof as to the correctness of the treatment that has been adopted.

Hospital Ship *Dreadnought*, July, 1866.

THE ARMY MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—His Royal Highness the Duke of Cambridge, with the silent assent of the Director-General of the Army Medical Department, has finally decided that the present condition of the Army Medical Officers must remain unaltered, and has totally ignored the just recommendations of a mixed and unprejudiced committee detailed by Government to inquire into our many grievances.

This denial of equity is entirely owing to the fact that at the last half-yearly Army Board Examination there were a sufficient number of candidates (chiefly Irish) to fill the vacant appointments, and who, by so acting, have effectually crushed for the present all the efforts and hopes of the many who have laboured for years to advance the unenviable status of the army and naval branches of our profession.

Should a similar influx of candidates take place at the next examination appointed to be held at Whitehall Yard on the 8th August, 1866, *there is no manner of doubt*—and it is a solemn and serious reality—that all our prospects of *genuine* relative rank, social position, promotion, pay, and retirement are for ever doomed.

This appeal is therefore forwarded to every Medical School in the United Kingdom calling upon the professors as well as students for the sake of justice and the honour of our profession to desist from permanently degrading the entire of your army and navy brethren, and cease to supply medical candidates for the vacancies of the army and navy at the next and subsequent examinations until the rights accorded us by the late Commission are duly approved of by the Horse Guards and the Admiralty and *insured* to us by Government.

"Amongst the Parliamentary documents issued during the last session is a return to the House of Commons of the number of Assistant-Surgeons at present in her Majesty's Service, exclusive of the Indian Army, and of the number

of Assistant-Surgeons promoted to the rank of Surgeon during the last three years, specifying the number of each year."

The return is very brief, but highly instructive. We quote it in its very words:—

"Return showing number of Assistant-Surgeons at present in her Majesty's Service, exclusive of the Indian Army, 738.

"Return showing number of Assistant-Surgeons promoted to the rank of Surgeon during the last three years:—

"Year ending 31st March, 1863	16
"Year ending 31st March, 1864	19
"Year ending 31st March, 1865	20

"The average annual rate of promotion for three years is simply 18, which 'goes into' 731 just 41 'times,' so that the last appointed Assistant-Surgeon in her Majesty's Service has the just expectation of being promoted at the end of forty-one years."—(vide *Lancet*, September 30, 1865, p. 381.)

This is the present prospect there is of promotion to Army Assistant-Surgeons. The rank of all in both the army and navy is "nominal" not "relative;" they can retire on pension only after a full service of twenty-five years, and during that period self-respect too frequently dwindles away, and gradually succumbs to a process of perpetual "snubbing," and for the sake of peace and years hard spent in every climate they have almost to barter all the feelings of gentlemen and often endeavour to forget the dignity due to themselves and their profession.—Yours truly,

ONE OF THE ABOVE.

June, 1866.

MEDICAL MEMBERS OF PARLIAMENT.

MR. BAXTER LANGLEY has just issued an address to the members of the Medical Profession in the borough of Greenwich, of which the following is a copy:—

"Gentlemen,—You will probably have seen by the public announcements that I am again a candidate for the representation of Greenwich, and I take the liberty of submitting a few of the reasons upon which, I think, I may have a claim to your support:—

"1. That I am member of the Royal College of Surgeons, and of some of the learned societies; and that I have devoted my attention for many years to the question of medical reform, having written upon it in the public journals so far back as 1842.

"2. That the medical profession is not sufficiently represented in the House, Dr. Brady and Mr. Clement being the only members of our body in Parliament.

"3. That medical representatives are more than ever necessary at a time when sanitary reforms of the most important character are under consideration; when the Poor-law Guardians are proved to be generally neglectful of the medical requirements of the poor, and are almost uniformly regardless of the respect due to the 'parish doctor;' when great works for the utilisation of sewage are being carried out; when, in a word, educated scientific opinion is wanted in Parliament.

"4. That the claims of the medical profession are not sufficiently regarded in the public services.

"5. That the laws for the protection of authorised medical practitioners are crude and ineffective.

"6. That, though a member of your profession, I have nevertheless made politics a study, and that as a writer and speaker upon public matters I am not unknown; whilst, as a 'man of business,' I believe that I am favourably known to most of you.

"Under these circumstances, I take the liberty of asking your support to my candidature, assuring you that the welfare of my professional brethren will always be a matter of the warmest and deepest interest to me.—I am, gentlemen, yours faithfully,

"J. BAXTER LANGLEY, M.R.C.S., F.L.S., &c."

~~~~~  
We understand that Dr. Rutherford Haldane, who has so long and so ably conducted the *Edinburgh Medical Journal*, has resigned his position as editor, and will be succeeded by Dr. Sanders, lecturer on physiology, and one of the physicians to the infirmary.

GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

THE following subscriptions have been further received on behalf of the above fund:—

—Yours obediently, ROBERT FOWLER, M.D.,  
Treasurer and Hon. Sec.

## SINGULAR DEATH OF A PHYSICIAN'S WIFE.

ON Wednesday evening the Brighton borough coroner was engaged for several hours in an investigation into the circumstances attending the death of Mrs. Ellen Vivian Warder, aged 35 years, wife of Dr. Alfred William Warder. The deceased lady was the sister of Mr. R. Branwell, a surgeon at Brighton, but neither she nor her husband resided there. They came on a visit to Brighton about two months ago and took lodgings in a house in Bedford-square. About six weeks ago Mrs. Warder was attacked with illness. Her husband himself attended on her till her brother, Mr. Branwell, called in the aid of Dr. Taafe, of Brighton. The rest of the case will be made clear from the subjoined evidence.

Mr. Stuckey, solicitor, Brighton, watched the case on behalf of Mr. R. Branwell, brother of deceased. Several medical men were present during the investigation, and the proceedings appeared to cause a great amount of interest. Dr. Warder was not present, having himself been attacked with illness since the death of his wife.

Richard Patrick Burke Taafe, said—I am a Doctor of Medicine and Master in Surgery of the University of London. About four or five weeks ago I was called by Mr. Branwell, the surgeon, who asked me to see his sister, and on the following day I did so. I saw Mrs. Warder, the deceased, and her husband. Mrs. Warder then complained of symptoms of strangury. Dr. Warder also said she had hysterical attacks, and in the absence of any other theory of disease to account for the symptoms, she appeared to me to be hysterical. I continued to attend her up to the time of her death. I prescribed for her the usual remedies to allay strangury. When I first saw her Dr. Warder told me he had been prescribing 20-drop doses of Fleming's tincture of aconite, as the only remedy to allay the pain of the strangury, which remedy had also produced tingling in her limbs. I objected both to the remedy and the dose, and substituted instead such remedies as henbane, tincture of castor, valerian, and laudanum and water fomentations. The remedies seemed to do her good, and I was also informed that she kept them on her stomach pretty well. I also prescribed valerianate of zinc. After some days I was informed that she had got tired of these remedies, and could not take them. Dr. Warder informed me so in her presence. I never saw her but in his presence. The symptoms and an account of her food were generally explained to me by him in her presence; being a medical man he could do so more accurately. I was told in her presence that sickness had supervened, and that she had vomited about twice a day; that her stomach loathed the remedies, and she could not retain them. I then desisted from giving her the remedies above mentioned, and gave her an effervescent saline draught, with aromatic spirits of ammonia and chloric ether contained in it. Finding that this even could not be retained, I substituted simple saline draughts, with one minim doses of prussic acid, Scheele's strength. When I wrote the prescriptions it was understood between myself and Dr. Warder that he would get them made up; being a medical man it was not unusual that he should do so. Even this did not succeed in allaying the sickness. I myself saw her take a draught which returned in five minutes after it was swallowed. She complained also of gripping pains in the abdomen. She was not purged, and I was informed in her presence that the matters vomited did not contain blood. Dr. Taafe described minutely the daily changes in the symptoms, and then continued as follows:—About ten days before her death a fresh symptom arose; her tongue presented a swollen appearance, its mucous covering white and soddened, as if it had been parboiled—the mucous membrane very much swollen. My attention was called to this appearance by Dr. Warder and the deceased, and the explanation given by Dr. Warder was that the previous day, in order to relieve the intense thirst of which she was complaining, and also with the intention of quieting the sickness, he had directed her to have an ice, or to suck small portions of ice occasionally, and that at night, after sucking ice continuously all day, she had drunk a cup of scalding hot milk and arrowroot, and Dr. Warder's notion was that the scalding hot fluid, taken after the cold ice, had produced this appearance. Deceased was present, and heard what Dr. Warder had stated. I prescribed effervescent draughts again, and in about forty-eight hours the tongue resumed its natural appearance. The mucous membrane seemed to separate and flake off, though I never saw any of the separated membrane. Most of her symptoms disap-

peared, and she seemed to get better. The strangury disappeared entirely, for she did not refer to it, and the vomiting, I was told in her presence and hearing, took place once in the twenty-four hours. About a week previously to her death her symptoms began to increase, and the strangury returned in as violent a form as before. I believe I saw her every day during the last week of her life, and on seeing her on Saturday last between three and four o'clock I was so struck with her appearance that I said to her husband, not in her hearing, that I intended to call upon her brother and suggest to him the advisability of having another medical man associated with me in the case. When I saw Mr. Branwell I suggested to him also that a regular nurse should be supplied to take the whole superintendence of the nursing, and I thought it would be better if she could be alone with such attendance for some days, her husband even not to be with her. Mr. Branwell and I agreed to meet at the deceased's house next morning (Sunday), but at half-past five that morning he was sent for and found his sister dead. On the Sunday forenoon, when I saw Mr. Branwell, we at once went to Bedford-square and saw Dr. Warder. I suggested there should be a post-mortem examination, and Dr. Warder said he had no objection. I asked Dr. Warder how she appeared to die? He said she got gradually weaker and weaker, and told him she had never felt so weak before in her life. I asked him if she had fainted suddenly, or had any attack or violent difficulty of breathing? He said "No; she seemed gradually to get weaker and weaker, and died." Witness then minutely detailed the results of the post-mortem examination made by himself, Dr. Withers Moore, and Mr. Jowers, on Monday morning, Dr. Warder being present. The body was well nourished; there was half to three-quarters of an inch of fat beneath the skin. Pleura and lungs healthy, slightly gorged at base, with frothy mucus at apices. The mucous membrane of the stomach was congested in a starlike form, especially near its junction with the gullet and its large end or curvature. At its upper end the mucous membrane peeled off easily. The stomach contained about eight ounces of a thickish brown fluid. The lining membrane of the gullet was softened, soddened, and of a whitish colour, and peeled off easily down to the muscular tissue, being friable and easily broken up into flakes. The papillæ of the tongue were raised at the root of that organ, and its mucous membrane was softened, soddened, and of a whitish opaque colour, and was torn off easily in large flakes. This appearance and character were continued down through the gullet as to its lining membrane. Both kidneys congested; the capsules easily torn off; the mucous membrane of their cavity especially congested, the left more so. The small bowels healthy, and contained a liquid similar to that in the stomach. The contents of these and the stomach were preserved. The liver was dark-coloured and gorged with blood. In the head, dura mater was pale; arachnoid distended with clear fluid; vessels of pia mater filled with dark blood. Brain itself generally healthy, but its cavities were filled with serum, and their roof and partition were softened, a stream of water washing them away.

Coroner—Now, as to the cause of death?

Witness—I am not in a position to state that there is any natural cause of death.

Coroner—Have you formed any opinion as to the cause of death?

Witness—Some time previous to her death—about fourteen or eighteen days—a painful impression arose in my mind that her death was resulting from unnatural causes. The incessant vomiting and spitting of blood first brought it to my mind. Then when she was recovering I did not allow my mind to dwell on it.

Coroner—You say you thought her suffering from something which was being administered to her?

Witness—Yes; in the absence of anything to lead me to a definite conclusion as to the diagnosis of the case. I did not communicate my suspicions to any one during her life, but I intended doing so if she had lived till the next day, to the second medical man who would then have been associated with me. That impression struck me more forcibly on the day previous to her death, and it was that which determined me to seek her brother and suggest a second medical opinion.

In further examination, Witness said that the contents of the stomach, part of the contents of the small intestines, a portion of the liver, one of the kidneys, the spleen, and a small portion of the small intestines had been deposited by

him in London with Dr. Taylor, the eminent analyst. That was done after consultation with the gentlemen who assisted at the post-mortem examination.

In answer to the jury, witness said that Dr. Warder told him that after he had objected to the aconite it had not been again administered. Latterly deceased had a ravenous appetite. He had ordered her nourishing diet. Deceased did not keep her bed on the Saturday. The ordinary dose of Fleming's solution of aconite was from three to five drops. Dr. Warder nearly always described the symptoms of deceased, but she was present and heard. Witness nearly always called at the same time of the day; Dr. Warder was particular that he should do so. He was always present when witness called.

Dr. William Withers Moore was present at the post-mortem examination, and agreed in every particular with the details given by Dr. Taafe. He could not reconcile the appearance of the body, taken as a whole, to any known natural cause of death that he was acquainted with. He had never seen deceased during life. He had come to his opinion quite independently of any other person.

Mr. Frederick William Jowers also assisted at the post-mortem examination, and was not able to assign any cause for death.

Charlotte Lansden, living at 36, Bedford-square, deposed that deceased and her husband came to lodge there on the 23rd of May last. Deceased did not appear to be ill when she came to her house. She saw deceased die. Dr. Warder rang the call bell about half-past five as near as possible. Witness sent her servant immediately, but the bell was rung a second time before the servant reached the room. She followed her servant immediately. Deceased was in bed and undressed. She was not able to speak, and seemingly unconscious. Her countenance was very calm. Deceased died about six o'clock. As soon as the servant got down stairs she was sent for Mr. Branwell. Just as Mr. Branwell arrived deceased breathed her last. Witness never took part in giving deceased any medicine. Dr. Warder usually attended on deceased and gave her food and medicine. Deceased had no servant of her own, and there was no one with her but her husband. Witness did not see deceased every day. The servant always put the vomited matter away.

By Mr. Taafe.—The arrowroot and milk was always sent up boiling hot, and I have remonstrated with her for drinking it so quickly as she used to do.

By Mr. Stuckey.—When I went into the room on Sunday morning, when called, Dr. Warder told me she was dying. I went up to the bed and looked at her. Dr. Warder was quite dressed. My servant had told me on the Saturday night that he was going to sit up. I then went and offered to assist him, but deceased herself declined my doing so. I had never given deceased food. Dr. Warder used to ask for me to do so if he did not get back in time to do so, but as a matter of fact I had never given her food. I should say I have a nephew staying with me who is about six years old, and when I have not been in the way he has often eaten all that has come down from the room of deceased, the beef tea and so on. The windows of the room were closed when I went in.

By the Jury.—I did not smell the slightest odour when I went into the room, and if there had been any I should have done so for my sense of smell is very keen. When he called us up Dr. Warder begged of my servant to go for Mr. Branwell. He said he had rung the bell immediately he had seen the change. Deceased could walk on Saturday. I offered to assist her to a hand-chair at the door, but she said she could do very well with Dr. Warder. He told me she had walked from the sitting-room to the bed room adjoining when she went to bed. I had given her food on one or two occasions, but not on Saturday.

By Dr. Taafe.—I do not know whether that remained on her stomach; I did not stop with her.

By the Jury.—We gave her no stimulants to keep her up during the half hour she lived after I went into the room. There were stimulants in the adjoining room, but not in the bed room. I asked Dr. Warder what she had taken, and he said about as usual. On Saturday night he had served out the essence of beef to make the beef-tea, from a canister which he had. I bought all the food they had in the house, except the beef essence from which the beef-tea was made. The medicine used to come mixed up in bottles in the ordinary way. Dr. Warder did not tell me when I went into the room, before she died, how long she had been in a sinking

state. He said she had slept a good deal during the night. I asked him, was she conscious of her end, and he said "No; you know how excitable she is." He also said that when she woke she complained of prostration. He did not say how long she had been awake before he rang. When she came to my house she said she was excitable, and that she did not wish any one about her, and, therefore, I did not intrude, and I did not see her frequently. Dr. Warder always remained with her when she was ill; she could not endure him to leave her for a moment. I never suggested a nurse, for she told me she preferred her husband to do everything for her.

At this stage of the proceedings the inquiry was adjourned for ten days, the coroner informing the jury that in the meanwhile he would direct Dr. Taylor to make an analysis of the viscera and the contents of the stomach and intestines.

ABSTRACT OF THE  
NINETEENTH ANNUAL REPORT  
OF THE  
COMMISSIONERS FOR ADMINISTERING THE  
LAWS FOR RELIEF OF THE POOR  
IN IRELAND.

TO HIS EXCELLENCY JOHN, BARON WODEHOUSE, LORD  
LIEUTENANT-GENERAL AND GENERAL GOVERNOR OF  
IRELAND.

Poor-law Commission Office,  
Dublin, 31st March, 1866.

MAY IT PLEASE YOUR EXCELLENCY,—We submit to your Excellency this the nineteenth annual report of our proceedings.

We submit a summary of weekly returns of persons relieved in the workhouse and out of the workhouse for fifty-two weeks, from the week ended 25th February, 1865, to the week ended 17th February, 1866, both inclusive.

Tables are submitted representing in figures the maximum, minimum, and average daily numbers relieved for the last seven years.

The progressive decrease of pauperism, which we noticed in our last annual report, considered apart from fluctuations incidental to different seasons of the year, has now again to be noticed as showing itself in a still more marked degree on a comparison between the last and the preceding years; the average daily number of workhouse inmates having undergone a further decrease of 3687, the difference between 55,808 and 52,121, or 6.6 per cent.

The average daily number of persons receiving out-door relief has in the same period increased from 8748 in the preceding year, to 10,040 in the last year, showing an increase of 1292 persons; but, as observed in previous reports, a small increase in the number receiving out-door relief indicates rather a change of practice in the administration of relief by the Guardians than any increase of distress.

It was noticed in the seventeenth paragraph of our last report that during the latter part of the year 1864, and the commencement of 1865, some alarm was caused by the prevalence of an unusual amount of fever, and, in some localities, of a bad type. On the 11th February, 1865, the number of fever patients in the workhouse hospitals reached the number of 2211, a greater number than had been known since the year 1855; the daily average during the intervening years seldom exceeding 1200. At the corresponding date in 1866, the number is shown by the table, in paragraph 1, to have been 1557, or 654 less than in 1865, showing an improved sanitary state in the population generally, and a further continuance of that immunity from epidemic typhus which has prevailed since the famine period.

In the deaf and dumb asylums of Ireland there is an average daily number of about 150, and in the blind asylums of about 200 inmates, supported at the charge of the poor rates of the several unions.

An Act was passed in the last Session of Parliament authorizing the Guardians of Unions, subject to the consent of the Poor-law Commissioners, to grant a superannuation allowance to any union officer who had devoted his whole time to the duty, and had become inefficient through old age or through permanent infirmity of mind or body.

We are enabled to report that the operation of this Act has been so far satisfactory, and that the Guardians have in several cases awarded, with our consent, the full amount authorized by the Act—that is to say, two-thirds of the salary. At the same time, the public advantage gained by parting with inefficient services in the way provided, has not been purchased by any serious amount of expenditure, especially when it is considered that some of the cases dealt with in the first instance may be regarded as cumulative through the previous absence of such a provision as that in question.

In reference to the remarks which we shall hereafter submit on the successful operation of Sir Robert Peel's Compulsory Vaccination Act, it may be here pointed out that the number of deaths in the workhouse hospitals by small-pox is only 59, in comparison with 145 in the preceding year.

Proceedings under the Medical Charities Act; the Act of 1858, "To make further provision for the practice of Vaccination in Ireland," and the Act of 1863, "To further extend and make compulsory the practice of Vaccination in Ireland."

There has been in the province of Ulster a decrease in the number of cases prescribed for at the dispensaries amounting to 11,095; and of cases attended at the patients' homes, a decrease of 354 cases. In the other three provinces there has been a considerable decline in the number of cases prescribed for at the dispensaries, and an increase in the number of domiciliary cases, amounting for the former class of cases, to 18,119 for Munster, to 22,229 for Leinster, and to 4259 for Connaught. While, on the other hand, there has been an increase in the latter class of cases of 740 for Munster, 1446 for Leinster, and 2704 for Connaught, giving, for the whole of Ireland, a decrease in the number of cases prescribed for at the dispensaries, amounting to the large number of 55,702 cases, and an increase in the number of domiciliary cases of 4536. A decrease in the former class of cases has occurred before on two occasions only since the enactment of the Medical Charities Act of 1851, but to a much less considerable extent than now. In the year ended September 30th, 1860, compared with the year before, there was a decrease in these cases amounting to 19,806, and for the year ended September 30th, 1864, compared with the preceding year, there was a decrease of the same class of cases of 6649. Taking the whole series of years since 1851, there has occurred a decline in the total annual number of cases receiving dispensary relief on three occasions, comparing, in each case, the year with that immediately preceding—viz., in the years ended September 30th, 1860, 1864, and 1865; but upon the whole series of years we find an increase in the total annual number of cases relieved from 690,411 in 1853, to 837,669 in 1865.

We submit a table giving the expenditure on dispensary medical relief in each province, and in all Ireland, for each of the last ten years ended, respectively, on the 29th of September.

For the first three years the expenditure was incurred solely under the Medical Charities Act, vaccination having been performed during that time as a part of the ordinary duty of the dispensary medical officers. For the last seven years the medical officers have received special remuneration for the performance of this duty, by fee for each case of successful vaccination, under the Act for the further promotion of vaccination of 1858, and that of 1863, to make compulsory the practice of vaccination in Ireland. To the operation of these Acts is mainly due the sudden increase of expenditure observable for the year 1859, and continued since.

We next submit a table giving the total expenditure under the three Acts above mentioned, digested under six heads, for the year ended September 29th, 1865.

Under the heads of salaries and medicines and medical appliances, there appears an increased expenditure for the last over that of the year before, amounting under the former head to £1275, and under the latter to £713. A small increase has taken place also under the heads of rent of dispensary buildings and vaccination expenses—viz., £98 under the former, and £329 under the latter head.

The average poundage on the poor-law valuation of Ireland, to furnish the total expenditure of last year, under the Medical Charities and Vaccination Acts, was 2·17d., or nearly 2½d., which is very slightly above that of the year before—viz., 2·16d.

The means do not exist of making any comparison of the former mortality by small-pox throughout Ireland, with the same as affected by the provisions of the Compulsory Vaccination Act, the causes of death not having been registered before 1864; and the Registrar-General's returns of the causes of death since that date not having yet been published. But from the weekly returns of mortality within the Dublin district (population 314,409), we are enabled to make a comparison between a period of six months ended 31st March, 1865, and a like period ending 31st March, 1866. The result is a decrease of deaths by small-pox from 52 to 4. Assuming the number of deaths to have been in the ratio of 1 to 5 to the number of attacks, we have a decrease of small-pox cases from 260 in 1864-5, to 20 in 1865-6. Whatever value may attach to results obtained for so limited a period, and within so limited a district, they are, to say the least, of good augury for the whole country and for the future; and it must not be forgotten that the class protected by the operation of the new Act is that which is most exposed to fatality by small-pox. Dr Farr calculates that 75 per cent. of the total mortality from small-pox takes place under the age of five years. It is probable that the average age of vaccination in Ireland, before the enactment of compulsory vaccination, was as high as this, and consequently, that three-fourths of the deaths that small-pox would ever have occasioned in a given population had already occurred before the protective influence of vaccination, as formerly practised, had been resorted to.

The success that has attended the Compulsory Vaccination Act during the past year is owing to the diligence and zeal with which the guardians, the magistrates, and the medical officers have very generally performed their respective parts in the enforcement of its provisions. A very few instances have come to our knowledge in which the justices in petty sessions have defeated the benevolent intentions of the Legislature, by imposing nominal fines on defaulters under the Act, and throwing the expense of the proceedings taken to enforce its salutary provisions on the guardians. It is to be hoped that these gentlemen will reflect on the calamitous consequences of their ill-judged lenity, and discontinue it. Otherwise, it will sooner or later assuredly happen that natural small-pox, being introduced amongst the unprotected children of their districts by itinerant inoculators, or accidentally, that virulent and most contagious disease will destroy every fourth or fifth child attacked, and of the survivors a certain number will lose their sight or hearing, or have their constitutions so broken as to be disabled from earning their livelihood in after-life.

However gratifying the amount of success already attained, it must be borne in mind by those to whose exertions that success is due, that much still remains to be done to ensure the complete and permanent success of compulsory vaccination; and that this result will only be secured by the steady enforcement of the penalty enacted against defaulters by the 8th section of the Act, till the poor all over Ireland become convinced that failure, on their part, to perform their duty by their children in this

respect, will very certainly be visited with the trouble and expense of prosecution and fine.

The Registrar-General for Ireland has registered the births of 144,638 children for the year ended March 31st, 1865, all of whom had come within the purview of the Compulsory Vaccination Act, at the close of the year ended September 30th, 1865. We may safely assume that the registered number of births is somewhat under the truth. Making a reasonable addition to it on this account, and a deduction from the sum on account of children vaccinated by private practitioners, and of children dying within six months after birth, we think it cannot be very wide of the truth to estimate that there were born in the course of that year about 130,000 children proper subjects for gratuitous vaccination by the dispensary medical officers. The number, however, actually vaccinated was 97,160, leaving the large number of 33,840 still to be vaccinated. We trust and anticipate that this excess, the measure of the degree in which the operation of the Compulsory Vaccination Act has fallen short of complete success, will diminish year by year till it shall nearly, if not entirely, disappear.

There has been a considerable increase in the number of cases of fever for 1865 compared with 1864, the numbers being for 1864, 21,586, and for 1865, 26,566. This excess arose from a prevalence of the disease which caused some alarm in the end of 1864 and beginning of 1865, lest it might indicate the commencement of one of those terrible epidemic visitations of fever which formerly so frequently, and during this century, till the time of the famine, with such singular regularity, afflicted Ireland, destroying great numbers of lives, and reducing to the condition of paupers great numbers of the poor.

In paragraph 15 of the Medical Charities Report for 1857 attention was directed to this subject. We said:—

“The quarterly reports from the medical officers of dispensaries for the year ended 29th September, 1856, show an increased prevalence of fever in the spring, and a subsequent very considerable decline in the autumn, but negative the existence of the disease to any serious extent in any part of the year. Nevertheless, the time being now at hand when, according to the lamentable experience of past times, a visitation of epidemic fever might be expected to occur in this country, we shall not fail to watch the indications of the returns with deep interest, and not without hope that a powerful proof of the improved condition of the people, in addition to the unmistakable ones we are already acquainted with, will be found in the mitigation of this scourge, which, for a long series of years, has returned with such periodic regularity and such terrible destruction of life. Severe epidemics of fever occurred in Ireland in 1799, 1810, 1816, 1826, 1836, and 1846. Any evidence of the absence of epidemic influence in respect to this disease at the present time is therefore highly gratifying; and we have the pleasure of being able to add that the returns from the fever hospitals of the workhouses completely confirm the evidence of the dispensary returns, inasmuch as they exhibit for the six months, from the beginning of April to the end of September, 1856, a tolerably uniform decline of fever, from 1806 cases in April to 1015 in September. It is true this decline of fever belongs to the season; but it is quite inconsistent with the supposition that an epidemic fever has commenced and is making progress.”

In the last of these epidemics recurring so regularly at each decennial period from 1816 to 1846, the number of cases treated in the temporary fever hospitals provided under requisitions of the Board of Health (and therefore exclusive of cases treated in other hospitals or for which removal to hospital was refused) was 332,462, with 34,622 deaths. It might naturally be supposed that this famine epidemic must have been preëminently fatal; but, owing perhaps to the fact that much of the fuel that would otherwise have fed it was destroyed by famine, or removed by emigration, this was far from being so. In the severe epidemic that commenced in 1816 there were treated in

the fever hospitals of Dublin, Cork, and Waterford alone in the years 1817–1819, 67,611 cases, with 2855 deaths; and in the admirable account of that epidemic drawn up by Drs. Barker and Cheyne, it is shown to be probable that “assuming the population of Ireland to amount to six millions, it will be no exaggeration to state that a million and a half of persons suffered from an attack of fever in the time included between the commencement of the year 1817 and the middle of 1819.” At the average rate of mortality of that epidemic, this amount of typhus would have been attended with 150,000 deaths.

The returns, now very nearly complete, of the number of cases of fever treated by the dispensary medical officers in the last quarter of 1865, give 5536 cases for that quarter, against 7109 for the same quarter of 1864; and at the end of the last week in December, 1865, there were in the workhouse fever hospitals 1478 cases, against 1881 at the same period in 1864.—We have the honour to be, your Excellency's obedient, faithful servants,

A. POWER.

C. P. FORTESCUE.

THOMAS A. LARCOM.

J. McDONNELL, M.D.

R. M. BELLEV.

### THE ARMY MEDICAL DEPARTMENT.

THE change in the Ministry is regarded by the Medical Officers of the Army and Navy as affording reasonable hopes of an improvement in their prospects. Instead of the Duke of Somerset and Earl de Grey and Ripon, who were known to be hostile to their claims, the management of these departments pass into the hands of Sir J. Pakington and General Peel, who have always shown themselves to be well disposed towards the medical profession.

The Chairman of the late Committee to consider the claims of naval surgeons will be a Lord of the Admiralty, and as that Committee has reported strongly in favour of the demands of the navy surgeons it is hoped that a more favourable administration has taken the question in hand.

As regards the prospects of the Army Medical Officers, the state of affairs is easily understood. The Committee which has reported in favour of improved rank and pay was appointed contrary to the wish of the Horse Guards authorities. It reported strongly against the opinion and action of the Horse Guards authorities. As a natural consequence it has been determined to delay the carrying out of the recommendations till it is absolutely impossible to avoid doing so. The following conversation on the subject took place lately in the House of Commons:—

“ARMY AND NAVY MEDICAL OFFICERS.—In the House of Commons on the 14th inst., Colonel North asked the Secretary to the Treasury whether the recommendations of the committee presided over by Admiral Sir Alexander Milne, relative to the medical officers of the navy and army, and which the authorities both of the navy and army had been for some time in communication with the Treasury, were likely to be decided upon shortly. He begged to remind the House that the committee reported early in February. Mr. Childers said, that in July last the College of Physicians wrote to the War office, complaining that the status of army surgeons was unsatisfactory, and to the Admiralty, that navy surgeons were, both as to pay and rank, not on a par with army surgeons. In consequence, the War Office and the Admiralty appointed a department committee, consisting of military and naval officers, and of medical men recommended by the College of Physicians and Surgeons, to inquire into the rank, pay, and position of the surgeons of the two services. The Treasury were not parties to the inquiry, and they had as yet only been officially in communication with the Admiralty on the subject. When the Government were in possession of the definite views of both the departments, they would be in a condition to deal with the cases of both the army and navy surgeons at the same time. The question was a very important one, involved a large amount of money, and required careful consideration.

Colonel North asked whether no communication had been received from the War Office. Mr. Childers said the War Department had not yet made their recommendations upon the report of the committee; but he personally had been in communication with his noble friend."

We have on former occasions declined to join in the statement persistently made by our contemporaries that the Army and Navy Medical Services were beneath the notice of the members of our profession who were looking for a field for their labours. We still maintain the opinion that, in spite of many injustices and grievances, those services afford a fair opening for a young medical man. It is now, however, the duty of surgeons to consider what course they will pursue in view of the following circumstances:—The Horse Guards and Admiralty authorities are awaiting with anxiety the issue of the next competitive examination, and they have postponed their acceptance or rejection of the recommendations of the Committee till they see what a month may bring forth.

As certainly as we write the words, if the next examination produces a sufficient supply of candidates the recommendations in favour of the profession will be repudiated, and all the grievances of army and navy surgeons will remain as they are; if, on the other hand, the requirements of the public service be not met, with almost as much certainty the redress will be accorded.

With such a prospect in view to reward them for holding back, we earnestly urge medical men to strain a point to meet the wishes of their brethren in the army and navy. If they will abstain from presenting themselves at the next examination they may calculate with reasonable certainty on a greatly improved position in future.

#### IRISH CANDIDATES FOR MEDICAL APPOINTMENTS IN THE PUBLIC SERVICE.

In another column we publish some well-timed observations which Dr. MOORE of Mercer's Hospital recently made to his Clinical Class on the above subject. If every clinical teacher in Dublin would but take a similar line, and dissuade young men from entering the public service for a short time, every reasonable demand *must* be conceded by the authorities; for unless there be a dearth of candidates, it is almost certain that things will remain in *statu quo*, on the ordinary commercial principle of the supply being equal to the demand.

Our Irish Medical Corporations are in honour bound to look after the interests of their alumni, and if the University of Dublin, the Queen's University, and the Irish Colleges of Physicians and Surgeons, would but unite in a strong memorial to the Secretary of State for War, while their alumni kept at a distance from army and navy medical examinations, the desired end would very soon be attained.

We are in a position to state that the King and Queen's College of Physicians has inaugurated a movement regarding this question, and we wish it success; but we think, at the same time, that success is much more likely to be attained as the result of an *united* effort, such as we now beg to suggest.

**DEATH OF THE BARONESS DUPUYTREN.**—The French journals announce the death, at a very advanced age, of the Baroness Dupuytren, widow of the illustrious surgeon.

#### STRAND WORKHOUSE.

THE report of Mr. Cane, the Poor-law inspector, on his recent inquiry into the treatment of the sick in the Strand Union Workhouse, has been laid before Parliament. For the most part it is confined to a summary of the evidence he took, and which, it will be remembered, related to the charges of the overcrowding of the sick wards, bad nursing, negligent administration of the medicines ordered, robbing the sick of their beer and wine, defective supply of linen for the sick, and uncleanly condition of some women admitted last year. Mr. Cane states by way of opinion or judgment of his own, that "it is manifestly clear from this inquiry that the workhouse has in many of its wards been for a long time seriously overcrowded, and that there has never been a proper staff of efficient nurses to attend upon the sick and infirm poor," and he refers to the evidence for a description of "the hardships and sufferings to which the inmates have been, and still are, exposed from these causes." The space prescribed for each person by the Hospital and Barrack Commissioners is 1200 feet; but in the Strand Workhouse the largest space in a sick ward is 748 feet, and in the nursery, which is used night and day, the space for each occupant when the ward is full is 218 cubic feet only, while the average cubic space for each inmate of a ward in constant occupation when all the wards are full is no more than 487 cubic feet. Mr. Cane has to state that at this time there are only two paid and 18 pauper nurses, and that the majority of the pauper nurses either cannot read writing at all, or read it so very indifferently that it is not safe to allow them to give medicines except under the immediate superintendence of others. "It is not surprising," he says, "that Dr. Rogers (the medical officer of the workhouse) does not consider two paid nurses sufficient to attend upon an average number of 487 sick, aged, and infirm inmates, 200 of them under medical treatment. There may be reasons why the guardians should feel embarrassed, and hesitate to carry out their resolution to build a new workhouse; but there are no reasons that I am aware of which prevent them from at once appointing a sufficient staff of efficient nurses and attendants upon the sick." Mr. Cane appends to his report letters from several ladies who have visited the workhouse; and who testify to the care and attention of the master and matron, and state that the writers always found the house clean and in good order. Miss L. Twining writes, "The master and mistress would, I believe, willingly welcome a reform, which can only be made by a change in the whole system and management of the sick."

#### Medical News.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on June 28th:—

Chatterton, Percy, Edgware-road West, Paddington.

Couch, James, Swansea.

Melhado, Alfred Courtney Bailie, Princes-square, Bayswater.

Trimnell, Edward Alfred, Lewisham-road.

The following gentlemen also on the same day passed their first examination:—

Anderson, Tempest, University College.

Gill, Henry Clifford, University College.

Powell, William, Charing-cross Hospital.

**THE INDUSTRIAL TENEMENTS COMPANY.**—We willingly direct attention to the useful and benevolent effort which is being made by means of a limited company to improve the dwellings of the poor in Dublin, and heartily wish it success. Its operations might afterwards be most advantageously extended to our provincial towns. The financial terms of the Company are set forth in our advertising columns, and the only amendment which seems desirable is, that weekly or monthly payments for shares should be accepted from the humbler classes—an arrangement which would thus confer on them the advantages of a savings bank and building society.

**THE CARLOW LUNATIC ASYLUM.**—In the House of Commons, on the 2nd inst., Mr. Bruen asked whether Dr. White, the Resident Superintendent of the Carlow Lunatic Asylum, had tendered his resignation; when that resignation was received by the Government; and whether a new Superintendent had been appointed, and the date of the appoint-

ment? Mr. Fortescue replied that the Resident Superintendent of the lunatic asylum referred to by the honourable gentleman did not resign, but died about a week ago. The Government accordingly had to consider the claims of a gentleman who was strongly recommended as his successor; and if that gentleman's qualifications had proved to be satisfactory, there could be no doubt that the appointment had been already made by the Lord Lieutenant.

COUNTESS WENCKHEIM has contributed a thousand bottles of splendid Tokay for the benefit of wounded Austrians. The Empress-Mother has given 10,000 yards of flannel for bandages. The bandagist, Vogl, has presented splints, &c., of the value of 1100 florins.

MR. CLEATON, resident medical superintendent of the Wakefield Lunatic Asylum, has been appointed a Commissioner of Lunacy in place of Mr. Gaskell. The appointment is worth £1500 a year.

ALUMINIUM.—A trial has just been made at Florence of a cuirass in aluminium, which is as light as an ordinary waistcoat, nearly as flexible, and capable of turning a musket ball fired at the distance of thirty-eight paces and of resisting a bayonet thrust from the heaviest hand.

ON THE ACTION OF SODIUM AMALGAM UPON HIPPURIC ACID.—When we make sodium amalgam to react upon hippuric acid and neutralize with sulphuric acid, two oily products are procured, which M. Otto has named respectively hydrobenzoic and hydrobenzyluric acids.—*Bulletin de la Societe Chimique de Paris.*

AN appeal has been published by the War-Minister to surgeons, even if not Prussians, to report themselves for voluntary service upon the medical staff, in order that provisions may be made for the cure of the enemy's wounded. The Queen has had the surgeons leaving for the army presented to her at the railway station.

WORKMEN are at present employed in the erection of two fountains in the quadrangle of the university which will, no doubt, prove ornamental as well as useful.

A SHOCKING outrage has been perpetrated by a chemist at Annfield, near Newhaven. Having quarrelled with two women he ran to his room and brought out a bottle containing some light coloured liquid, which he threw over them, producing serious injury to the eyes of the one and the neck of the other. The fluid was most likely sulphuric acid, or some other corrosive substance; and the perpetrator of this dastardly crime has been apprehended.

GREAT alarm has been caused in Leith by the arrival, last week, of a screw steamer from Stettin with a cholera patient on board. On coming into port the master reported that one of his seamen had been ill for some days with diarrhoea, and had been confined to his berth in consequence. As it was well known that cholera has been prevalent at Stettin of late, Dr. Williamson, the medical officer of health, lost no time in visiting the vessel. He found that the patient presented symptoms of cholera, and directed that all communication between the steamer and the shore should be forbidden, at the same time advising that she should be taken down to the Roads and anchored there. The vessel was fumigated, and every precaution taken to prevent an outbreak of this dreadful scourge. Subsequently the sick man was removed on board an old vessel moored in the harbour, where we believe he is convalescing. An hospital for the reception of cholera cases is to be erected immediately on the West Pier, and the customs' officers and police at the docks have been ordered to keep a sharp look out on all foreign vessels coming into port, and to report without delay any case of illness that may be found on board. In the meantime the Health Committee are exerting themselves to the utmost in order to place the town in the most favourable sanitary condition, and with a view to this the closes have been all lime-washed, and the drains repeatedly flushed with water. We trust that these measures may be effectual in preventing the spread of the pestilence.

ON Wednesday last a meeting of considerable interest and importance was held in the Waterloo Rooms, Edinburgh. It was composed of medical men chiefly from the villages and country districts of Mid-Lothian, and the object of the meeting, as stated by Dr. Fowler of Ratho, who

presided, was to endeavour to form an association for the protection of the interest of medical practitioners, especially for those members of the profession who practised in the country districts. The chairman alluded, amongst other things, to the difficulty that was experienced in getting accounts collected, owing chiefly to the shifting character of the working population, suggested that medical men should, at the end of every half year, send in their bills for attendance upon the farm labourers and their families, to the employers, with the view of having the amount deducted from the servant's half yearly wages. He likewise suggested that in the case of those who removed from one parish to the other without settling their doctor's bills, notice should be sent to the doctors in the district in which they should settle, who ought then to refuse to attend such persons, unless under circumstances of pressing need. Dr. Fowler added that, notwithstanding the commercial view of an matter which, in suggesting the formation of this society, they were taking, there was not one of them who would not do all he could to prevent the rules of the association from coming into collision with the claims of humanity, and to maintain the reputation of the profession for charity and liberality. A resolution to the effect, that an association to be called the Lothian's Medical Association, should be formed for the purpose of carrying out the purposes of the meeting, was agreed to; and a committee, with Dr. Stephenson of Edinburgh as secretary, was then appointed. The meetings of the society are to be held weekly.

ON Thursday afternoon Mr. Griffin received at the Freemasons' Tavern the handsome testimonial that has been subscribed for his energetic efforts in behalf of Poor-law Medical Reform. The testimonial consisted of a fine épergne, representing the good Samaritan relieving the unfortunate man who fell among thieves, together with an album containing the photographs of the subscribers. The meeting was quite a success, as a still further demonstration of the rights of the English Poor-law Medical Officers.

IN the theatre of the College of Surgeons are now exhibited the additions made to the Hunterian Museum during the last year, some of which are particularly interesting. We have just spent some time in inspecting them, and have been somewhat surprised at their extent. The preparations comprises important purchases as well as donations. We observed amongst them Dr. Bell Pettigrew's dissections, illustrating the arrangement of the muscular fibres of the human bladder, recently described in his paper read at the Royal Society. There is a corresponding set relating to the voluntary muscles. Amongst some splendid injected pathological specimens, are an enlarged breast, and an osteo-sarcoma, both of which were removed by Sir Wm. Fergusson. Messrs. Curling, Hilton, Wormald, and Bush, as well as others, have also contributed valuable specimens. The collection is to remain on view only until the 12th instant.

DECLINE OF THE CATTLE PLAGUE.—The cattle plague continues to decline in a satisfactory manner since the adoption of a policy of isolation and slaughter. The number of cases reported in the week ending June 23rd was 467. The cattle plague has now entered upon its second year.

MODE OF RESUSCITATING PATIENTS DYING FROM CHLOROFORM INHALATIONS.—M. Lefort stated at a late sitting of the Surgical Society of Paris that he believes death to occur in these cases from syncope—i.e., want of cardiac contractions. He considers artificial respiration useful, because it forces blood from the lungs into the heart. A more efficacious measure, according to M. Lefort, is galvanism, with one pole placed along the spine and another on the epigastrium.

HIS ROYAL HIGHNESS THE PRINCE OF WALES has subscribed one hundred guineas, for the purpose of aiding the establishment in Ireland of an institution for the protection, training, and education of idiotic and imbecile children.

THE *Eolus* frigate of forty-two guns has been fitted as a hospital ship, and moored at the entrance to the river Itchen, for the use of seamen on board of German steamers calling at the port of Southampton.

THE nineteenth annual session of the American Medical Association was opened at Baltimore on the 1st ult.

About two hundred delegates were present. Dr. D. A. Storer, of Boston, the president elected last year, occupied the chair. Dr. Montrose A. Patten, who last year was expelled from the Association, was unanimously reinstated, having been fully exonerated by the committee to which the papers in his case were referred.

On Saturday last a boy, eight years of age, the son of Mr. Isill, Willesden, died in St. Mary's Hospital from hydrophobia. It appears that he was bitten by a dog in May last.

## Notices to Correspondents.

*Cyclops*.—The letter has been received.

*J. E., Dreadnought*.—The letter is inserted.

*Dr. Fowler*.—The letter is inserted.

*Dr. Andrew Paul*.—The proposed cases will be acceptable.

## Vacancies.

*Cheltenham Union*.—Workhouse; salary £45 per annum.  
*Charley Union*.—Croston District; area 10,125; population 5369; salary £20 per annum.  
*St. Thomas Union*.—Tedburn St. Mary District; area 4433; population 768; salary £9 12s. per annum.

## Appointments.

**I. ASHE, M.B., C.M.**, has been elected Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Warrenpoint Dispensary District of the Newry Union, Co. Down, vice J. Robinson, L.K.Q.C.P.L., resigned.  
**L. C. BADCOCK, M.D.**, has been appointed House-Surgeon to the Brighton and Hove Dispensary, Queen's-road, vice C. V. Willett, M.R.C.S.E., resigned.  
**G. H. BARLOW, M.D., F.R.C.P.L.**, has been appointed Physician to the Asylum for the Deaf and Dumb, vice B. G. Babington, M.D., deceased.  
**P. BRADY, L.K.Q.C.P.L.**, has been elected Surgeon to the Clonmellon Dispensary District of the Delvin Union, vice W. Murray, L.R.C.S.Ed., elected to the Delvin Dispensary District.  
**J. D. CLEATON, M.R.C.S.**, Resident Medical Superintendent of the West Riding Lunatic Asylum at Wakefield, has been appointed a Commissioner in Lunacy.  
**W. H. COPE, M.R.C.S.E.**, has been appointed Medical Officer for District No. 4 of the Croydon Union, Surrey.  
**W. E. CREASY, M.R.C.S.E.**, has been elected Medical Officer to the Asylum for Female Orphans, Westminster-road, Lambeth, to attend the Asylum when the children are removed to the new building at Beddington, near Croydon.  
**Dr. W. MACDONALD, of Daviot**, has been appointed House-Surgeon to the Northern Infirmary, Inverness, vice D. Campbell, resigned.  
**R. D. TANNABILL, M.D.**, has been appointed one of the Physicians to the new Dispensary for Women and Children in connexion with the Glasgow Lying-in Hospital.  
**EBEN. WATSON, M.A., M.D.**, has been appointed Surgeon to the Royal Infirmary, Glasgow.  
**Dr. J. C. ROBERTS of Nunhead**, has been appointed Public Vaccinator for the South Peckham District of the Camberwell Parish.  
**W. C. SEAMAN, M.D.**, has been elected a Fellow of the Zoological Society.  
**T. J. FITZPATRICK, L.K.Q.C.P.L.**, has been appointed Medical Officer for the Hornton District of the Banbury Union, Oxfordshire, vice James Taylor, L.F.P. & S. Glasg., resigned.  
**H. C. LAWRENCE, L.R.C.P.Lond., M.R.C.S.Eng., and L.M.**, has been appointed House-Surgeon at the Bath United Hospital.  
**H. J. JOHNSTONE, L.R.C.P.Ed.**, has been appointed Medical Officer to the Crossakel Dispensary District, county Meath, and Surgeon to the Constabulary, vice M. Davidge, L.R.C.S.Ed., deceased.  
**W. MURRAY, L.R.C.S.Ed.**, has been appointed Medical Attendant to the Constabulary, Clonmellon, county Westmeath, vice M. Davidge, L.R.C.S.Ed., deceased.  
**Dr. J. W. PATRICK** has been elected Medical Officer for the Carrickfergus Dispensary District of the Larne Union, county Antrim, vice W. H. Patrick, M.R.C.S.E., deceased.

## WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING JULY 7TH, 1866.

By J. II. STEWARD, Strand, and Cornhill, London.

## To the Electors of Dublin University.

GENTLEMEN,—

In anticipation of a vacancy in the Representation of the University, I beg to offer myself in that event as a candidate for your suffrages. I do so at the suggestion of several influential friends, and with the promise of extensive support.

A consistent Conservative in politics, I believe I agree with the large majority of the Electors upon all the great questions that occupy public attention. If chosen to represent you in Parliament, I shall resist all hasty or ill-considered changes in the Constitution.

Sincerely attached to the United Church of England and Ireland, I shall strenuously maintain its rights in this country.

As to the important subject of Education, I feel strongly the injustice of a system which excludes so large a number of conscientious men from participating in the funds devoted to that purpose, and I should be anxious to concur in any measure for the satisfactory settlement of the question on terms which would enable the great body of the Clergy to take advantage of the grant.

Led by my professional pursuits to the study of Ecclesiastical Law, I may, perhaps, claim to be qualified to represent usefully a constituency of which the Clergy form so large a portion.

Should you do me the honour of returning me as your Representative, I shall endeavour, by constant attention to public duty and the interests of the University, to deserve the confidence which you may repose in me.

I have the honour to remain,

Your obedient servant,

JOHN E. WALSH.

10, Trinity College, Dublin, June 30, 1866.

## To the Electors of the University of DUBLIN.

It being now tolerably certain that a vacancy will immediately take place in the Representation of the University, I beg leave to offer myself as a candidate, and to place before you a statement of my political principles.

I am desirous of maintaining, in its fullest efficiency, the Established Church, to which I am warmly attached, and am resolved by all means in my power to resist any assault upon it.

I am, and have ever been, a steady supporter of the principles of that Constitution under which our country has enjoyed true freedom. I shall oppose all projects tending to disturb its balance, or conceived in a democratic spirit, while ready to give my support to well-considered measures for its real improvement. I shall, therefore, ally myself with the great Constitutional party of the State, who will be found to possess more true liberality of sentiment than those who have so long arrogated that quality to themselves.

On the difficult subject of National Education I can here only say that I shall use my best endeavours to effect such changes in the system as will enable our clergy to avail themselves generally of the grant without doing violence to their consciences.

If elected, I shall devote my best exertions to advance the interests of our University.

HEDGES EYRE CHATTERTON.

Committee Rooms, 7, Trin. Coll., July 4th, 1866.

## QUEENSBERRY LODGE, EDINBURGH. ESTABLISHED 1866.

FOR THE ACCOMMODATION AND REFORMATION OF FEMALES OF THE BETTER CLASS ADDICTED TO INTEMPERATE HABITS.

## The Numerous applications which have

from time to time been received by the Directors of Queensberry House to provide accommodation for Females addicted to habits of intemperance, and the want of room at their disposal in the present Building to meet these demands, as well as to admit of proper classification, led them to see that there existed a necessity for a separate Building, which should be devoted exclusively to the reception of Females of the better class who are thus afflicted. The Directors have now to intimate that a Suitable House, in an open and healthy locality, immediately adjoining the Queen's Park, has been built; and it is expected that it will be furnished and open for the reception of Boarders by the 1st of AUGUST NEXT. The new Institution is under the same Management of Directors, Governor, Physician, and Chaplain, who have so long and so successfully superintended the affairs of the old Institution; and the Public have thus a sufficient guarantee that the arrangements will be conducted in such a way as to secure the confidence of the community. Applicants or their Friends are required to sign a Form of Application for Admission, voluntarily consenting that the Applicant shall become a Boarder, subject to the Rules of the House.

Further particulars may be obtained from Mr. THOMAS P. NELSON, House Governor, or Miss DONALD, Matron, Queensberry Lodge, Edinburgh.

## COUNTY OF DOWN GAOL.

The Board of Superintendence will proceed to Elect an APOTHECARY, at Two o'clock p.m., on the 25th July, 1866. Salary £27 18s. 10d. per annum. Testimonials to be lodged in the Board-room before Twelve a.m. on that day, when a personal attendance of the Candidates will be required.

JAMES STEVENSON, Local Inspector.

## Original Communications.

### CLINICAL RECORDS ILLUSTRATIVE OF THE DISEASES OF CHILDREN.

By G. STEVENSON SMITH, L.R.C.S.E.,

FELLOW OF THE OBSTETRICAL SOCIETY, AND FORMERLY RESIDENT MEDICAL OFFICER, ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.

#### VI.

#### CANCNUM ORIS, OR GANGRENOUS STOMATITIS—TWO FATAL CASES.

THE following cases present a very graphic and faithful picture of a disease, which, in its severest form, is always most loathsome and hideous, and generally terminates in death.

Fortunately cancrum oris is, comparatively speaking, a rare affection, and those in this country who have had the largest experience of the diseases of childhood are able to count on their fingers all the examples of this frightful malady which have come under their personal observation.

The patients whose cases are here recorded were, curiously enough, seized with illness about the very same date; they were both patients at the Childrens' Hospital, where they died within a very short time of each other.

There are some points of interest in connexion with both cases, to which I am anxious to allude before proceeding to give the particulars in detail.

In Case 1 it will be noticed that, previous to the swelling of the face and the factor of the breath, the child had been ill for about twelve days, having had rigors and other symptoms of what the mother thought was a "bad cold." Moreover, there had been an outbreak of continued fever in the close where the patient resided; and it is, therefore, extremely likely that previous to the appearance of the gangrene, the child had suffered from a febrile attack. And this is what is generally observed in the majority of cases of cancrum oris; the patient has been previously weakened and prostrated by some illness. Idiopathic gangrene of the mouth—that is, gangrene coming on suddenly in a child who had been previously in perfect health—is very rare indeed, so rare that out of twenty-nine cases of cancrum oris, MM. Rilliet and Barthez found that only one appeared to be an instance of the disease in that form.

The apparent absence of pain, and the extraordinary placidity with which the poor little patient bore the ravages of the dreadful malady, are also worthy of remark.

Pneumonia is stated to be of very frequent occurrence in the course of this disease; and although in Case 1 no post-mortem examination was allowed, there were some evidences in the dulness at the lower part of the right lung, and the short cough, of the presence of that affection.

The urine in this case was found on admission to be alkaline in its reaction, and of sp. g. 1012, while the presence of membranous scales, and numerous rounded epithelial cells, with one nucleus, each was revealed by the microscope.

In Case 2 there had also been a prolonged period of ill health antecedent to the appearance of the gangrene. But this case is chiefly interesting on account of the evidence it furnishes of the fatal attack of cancrum oris having originated in, and been preceded by, an attack of

ulcerative stomatitis. For a whole month before the child's admission to the hospital the incisor teeth of the upper jaw had been gradually rotting away, the gums round the stumps were tender and bled frequently, and the breath had an offensive smell. Here we have very clear proof of the existence of ulcerative stomatitis, which had commenced about the beginning of December, 1865, and it was not till the 1st of January, 1866, that the swelling of the face and other symptoms betokened the presence of the more serious disease. The termination of ulcerative stomatitis by gangrene is rare, Dr. West having out of a very large number of cases only met with one instance; but the very fact that an attack of ulceration of the gums may end in fatal sloughing, should lead us to be on our guard when such cases come under our care.

Another point of interest in this case is the tendency to sloughing of the integuments which was manifested—a tendency which I have not seen alluded to by writers on this disease. On the arms, face, neck, and thumbs, there were numerous blistered patches which, when broken, discharged dirty-looking sero-purulent matter, and continued to throw off an unhealthy discharge from their raw surfaces afterwards. This tendency to ulceration of the skin was manifested likewise in Case 1, though not to the same extent, for in her the skin over the sacrum, which for a day or two presented a purple appearance, became disorganized before death.

In Case 2 these blisters assumed the character and appearance of *plyctenae*, which are frequently seen in gangrenous disease of other parts of the body.

The urine was of sp. g. 1021, and contained albumen, along with numerous reddish brown membranous scales and a copious deposit of urates.

With these preliminary observations I shall now narrate the particulars of the two cases in detail:—

*Case 1.—History.*—E. R., aged 4, first showed symptoms of illness on New Year's day, 1866, when she had rigors and seemed to be suffering from cold. She likewise complained of pain in the right ear, and her whole body was tender to the touch. Patient never had any of the diseases of childhood, except whooping-cough. Continued fever had been prevalent in the close where the child resided.

On the 12th of January a swelling of the right cheek was noticed by the mother, and the breath smelt badly. A medical man had seen the child and prescribed some simple gargle for the mouth. This swelling, however, gradually increased in size, and the patient went from her food.

*State of the patient when first seen by me.*—I first saw the child on the 26th of January, nearly four weeks after she had turned ill, and a fortnight after the swelling of the cheek had been observed.

The skin was then of a dirty greenish hue; the pulse 132 and feeble; the extremities cold. On the right cheek there was a rounded swelling about the size of a small apple, glossy, and shining on its surface, and when touched, communicating to the fingers a soft elastic feeling. Extending from the right angle of the mouth to the ala of the nose was a brownish black patch, about half an inch in breadth, dry and soft on its surface, and resembling fine chamois leather to the touch. This patch I learned from the mother had first shown itself as a fiery red spot a few days previously, and had assumed its dirty black colour the day before.

On looking into the mouth, masses of dirty disorganized pultaceous-looking matter were seen hanging from the inside of the right cheek; and the whole of the internal surface of the cheek on that side was in a state of putridity. The gum of the upper jaw had become disorganized also, leaving the alveolar process blackened and bare. The teeth were quite loose, but the tongue was moist and natural. The factor of the breath was most offensive and sickening, and a stream of bloody saliva trickled away from the mouth.

The patient was quiet, and appeared to suffer no pain.

*Treatment.*—A warm bath was given, which had the effect of raising the temperature of the body; and ten grains of the chlorate of potass with five minims of the muriated tincture of iron were ordered to be administered every two hours. Sherry, strong beef-tea, and milk, were likewise prescribed in frequent doses.

With the object of destroying the sloughy textures, the inside of the cheek was touched freely and thoroughly with strong nitric acid, and the mouth was afterwards syringed with a weak solution of chlorinated soda. The application of the acid gave no pain. In order to keep the atmosphere of the apartment as sweet as possible, towels were wrung out in diluted Condy, and suspended in the room. Free ventilation was at the same time maintained by keeping the window open, and a good fire burning.

*The urine.*—Sp. g. 1012, faintly alkaline, and of a turbid appearance. A microscopic examination revealed membranous scales, some of which were granular, and some stained yellowish brown; numerous rounded epithelial cells, containing one nucleus each, and a few bright greenish tinted corpuscles, were also visible.

*Vesperi.*—The ulceration has spread externally; the margins of the gangrenous patch being of dirty white colour. The edges and entire surface of this patch were now touched with the nitric acid. There has been slight bleeding from the right nostril, and patient has vomited once or twice; pulse 132, and very feeble.

January 27th: Externally the disease continues to spread, the gangrene extending upwards; breathing is quiet; pulse 130 and weak. There is an occasional short cough, and percussion elicits some dullness over the right lung inferiorly. Eleven p.m.: Externally the ulcer was touched with a weak solution of carbolic acid. The child rests quietly, and continues to swallow without difficulty.

January 28th: The swelling of the cheek continues to increase, and the disease is rapidly extending upwards towards the eye. After each time that the cavity of the mouth is syringed out, little portions of the broken down textures are washed away.

January 29th: The right half of the nose is now entirely destroyed, and the nasal bone is bare, and of a charred appearance. The slough in the cheek, which measures about an inch and a half in diameter, and is of a dirty coffee-brown colour, is becoming detached superiorly, and hangs out, exposing the malar bone and the cavity of the mouth. A charcoal poultice was applied to the whole of the diseased parts. Over the sacrum there is a purple-coloured transverse mark, about two inches in length and a quarter of an inch broad. Patient is extremely weak, but still swallows well.

January 31st: Bowels, which up till this time have been rather constipated, became very loose this morning. The gangrenous margin is close up to the right eye, and has now destroyed the lower eyelid. Inferiorly the line of the upper lip is still intact. The colour of the skin is dingy yellow. The feet are œdematous.

Towards evening patient began to vomit everything she swallowed, but lay very quiet, was quite sensible and composed, and apparently suffered no pain. One or two teeth are quite loose, and were easily removed by the fingers. Pulse rapid and extremely thready. The purple mark over the sacrum has ulcerated. Patient lingered on through the night, but died quietly early in the morning of February 1st.

No post-mortem was allowed, but a cast of the face was taken.

It was seen that the gangrenous action had involved the whole thickness of the cheek, and a cavity, measuring two inches in width, and extending from the lower border of the eye to the level of the upper lip, had been exposed. The right nasal, malar, and part of the upper jaw bones, were quite bare and blackened. The brownish, black dead slough was quite detached above, but was still held in its place below by the line of the upper lip. Around the margin of this horrible ulcerated excavation there was a circle of a bluish-green tint, about a quarter of an inch in width.

*Case 2.—History.*—J. S., aged 3; was never very robust, and about a year ago suffered from measles; six months ago he was seized with hæmoptysis, accompanied by a violent cough, which lasted till October last.

I first saw him on the 5th of January, 1866, and was told by his mother that more than a month before that date his two upper incisor teeth had rotted away, and the gums round the stumps were tender and bled frequently, while, at the same time, the breath smelt very badly. About two weeks before I saw him he had had a slight feverish attack, and was prescribed for by a medical man, after which he improved considerably, and was able to be out of bed. On the 1st of January it was noticed that the left side of his face was swollen, and bloody saliva trickled from his mouth, staining his shirt and the bedclothes. The bowels were loose, and very dark in colour. On the 2nd, elongated blisters appeared on his arm and face.

The house in which the patient resided was one of the darkest and worst ventilated hovels in the Cowgate, and consisted of one small apartment into which daylight never penetrated. In this wretched abode a family of seven persons resided.

*State of the patient when first seen on 5th January.*—The stench from the boy was dreadful; the left cheek was swollen to about the size of an orange; the lip was also swelled, and the eye on the same side was nearly closed; the mouth was distorted. The surface of the affected cheek was of a pale olive colour, had a glistening appearance, and to the touch felt like a tense elastic ball. There was not the slightest blush of redness on the cheek; there were two dirty-like fissures of the upper lip. Inside of the mouth, so far as could be seen, for there was much difficulty in separating the jaws, a slough of a dirty dark greenish appearance could be seen, covering the internal surface of the left cheek, and extended over the roof of the mouth to about the middle line; the tongue was perfectly clean and moist. On the face, neck, arms, and thumbs there were several shrivelled blistered patches of a greenish colour. The pulse was 144, and feeble; respiration hurried; the skin of the whole body was of a dingy yellow colour, and the feet were slightly œdematous. The power of swallowing was not much impaired.

*The urine.*—Sp. g. 1021, of a reddish colour, and contained albumen. Under the microscope an abundance of amorphous urates were seen, along with numerous reddish brown membranous scales of an irregular oval form.

*Treatment.*—Ten drops of the liquor potassæ perman-ganatis were directed to be given every two hours, and the chlorate of potass was to be mixed with all the fluid he drank. The whole of the sloughy surface inside the cheek was touched with the strong nitric acid, a glass brush being used in the application, and the mouth was frequently syringed with a solution of chlorinated soda. The application of the acid gave almost no pain. When the mouth was washed out some of the sloughy débris came away.

January 6th: At two a.m. patient was resting very quietly, and was able to swallow small quantities of fluid.

In the course of the day, however, a choking gurgling rattle in the throat always followed when the patient attempted to swallow; the pulse was so feeble as to be almost imperceptible, and the surface of the body was cold. The gangrene has not spread much, but the stench is still dreadful. The appearance of the inside of the mouth is much the same as it was yesterday, only now shreds of sphacelated texture hang from the inside of the cheek and palate. Nitric acid was again applied to the sloughs, and the mouth washed out with Condy's fluid and water. Enemata of strong beef-tea and brandy were administered.

*Vesperi.*—Towards evening a dark brown spot made its appearance externally, near the angle of the mouth, and continued to extend towards the centre of the cheek; the spot was dry, and there was no discharge from its edges. Child lingered on till about two a.m. in the morning of the 7th January, and died quietly without any struggle.

No post-mortem could be obtained. After death, however, I made an incision through the substance of the affected cheek, and from the appearance of the parts it was evident that the disease had commenced internally and gradually extended outwards. The dark spot on the cheek was now coal black, and surrounding it were two rings of different hues, the internal one being purple, the outer of a dark blue colour.

The left half of the soft palate and of the lower jaw, as well as the whole surface of the cheek internally, were covered with a dirty brownish putrescent matter, and the teeth on that side were all loose.

It is worthy of notice that a sister of this patient's, aged 4 years, died of typhoid fever about a fortnight afterwards.

In both cases, it will be observed, the treatment was nearly the same. The application of the nitric acid was made more with the view of destroying the sloughs, and thereby removing a fertile source of contamination, than in the hope of arresting the gangrene. The disease in both instances had gone too far, and was too deeply rooted to lead us to look for the latter result.

But cases are on record (see West, p. 571, and an article on "Cancrum Oris," by Dr. Keiller in the *Edinburgh Medical Journal* for April, 1862), in which the free and determined cauterization of the diseased parts by strong acids had the happy effect of arresting the progress of the malady, and saving the patients. It is only, however, when the disease is seen in its early stages that such treatment, or indeed that any treatment whatever, can prove successful. The application of the acid is not attended with any great pain.

In Case 1 the application of a weak solution of carbolic acid to the sloughy textures was attended by some good, in so far as checking the fœtor was concerned. It is, doubtless, of the very greatest importance to endeavour, if possible, to neutralize the dreadful stench which is always given off from the disorganized textures in this affection, for there cannot be a doubt that Dr. Keiller's views are correct on this point when he says: "It is, I consider, by no means improbable that death ensues in such cases not so much from any previous diseased condition or contamination of the blood, as from the continued and unavoidable inhalation of the poisonous products arising from the gangrenous degeneration within the mouth."

And one means by which we may strive to prevent this contamination of the blood is by the frequent use of gargles of chlorinated soda, dilute Condy's fluid, dilute carbolic acid, and the like. These are all best applied by means of a syringe.

But besides mere local remedies constitutional treatment must likewise be carried out.

The chlorate or permanganate of potass, and some of the preparations of iron or quinine, are the agents which are particularly indicated, while stimulants and a liberal supply of fluid nourishment will in most cases be required. But seeing that in these cases we have to do with poisoning of the blood, it has occurred to me that the inhalation of oxygen gas might be of benefit in cancrum oris. This agent has been used with success in many diseases by Trousseau, Demarquay, and others, and the mode of administration consists in making the patient inhale pure oxygen from an apparatus which has been constructed for the purpose. Such a remedy is, I think, well worthy of a trial in our Children's Hospitals, where cases of cancrum oris not unfrequently turn up.

**THE CHOLERA.**—There seems great probability that cholera will continue to spread. Although decreasing at Amiens, it is much on the increase in other French towns. At Antwerp, also, 40 deaths in one day have been reported. In Berlin, 76 cases, of which 50 were fatal, occurred on the 30th June. In Southern Russia we also hear that it is making progress, and it has broken out at St. Petersburg.

THE RINDERPEST OF THE PRESENT TIME,  
AND  
THE CATTLE PLAGUES OF PAST AGES,  
IN THESE ISLANDS,  
AND ON  
THE CONTINENT.

By THOMAS MORE MADDEN, M.D., M.R.I.A.,

No I.

ITS SYMPTOMS—NATURE—CAUSES—DIAGNOSIS, PREVENTION AND TREATMENT.

(Continued from page 32.)

THE diseases with which rinderpest may be most easily confounded are pleuro-pneumonia, the "mouth" and "foot diseases," and puerperal fever. Of these the most commonly met with in Ireland is pneumonia, which, as I have shown, has prevailed extensively in the country ever since 1842, and which is asserted by many to have been the disease which appeared at Drennan in May last. In favour of this assertion we have the fact that pneumonia is generally most prevalent among cattle at this time of year, and that it is always increased by the long continuance of easterly winds, such as preceded the cattle disease at Drennan. The symptoms of pneumonia and the other diseases are, however, I think, sufficiently distinct from those of

| PNEUMONIA.                                                                                                                                                                                                                                                                          | MOUTH AND FOOT DISEASE.                                                                                                                                                                                                                                                                                              | RINDERPEST.                                                                                                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attack gradual; a dry short husky cough; tenderness on pressure over the diseased lung; appetite impaired, but not lost; eyes bright and clear; fœcal discharge natural till near death, when diarrhœa sets in; no discharge from eyes or nostrils; animal may live thus for weeks. | Attack sudden; animal smacks the lips, from which a quantity of rosy saliva flows; the tongue and lips covered with large white blisters; sometimes affects the feet; blisters between the toes, causing a peculiar walk; circulation and fœcal discharge natural; is seldom fatal, and lasts only for a short time. | Attack gradual; a peculiar weak and languid appearance; heads and ears drooped; temperature high; eyes congested and dull; frequent moaning; loss of appetite; mouth and vagina intensely red; great loss of power; milk stopped; diarrhœa towards end; death about seventh day. |

Whether the rinderpest be communicable to non-ruminant animals or not, is a point on which there is yet much doubt. It is certain that sheep and goats have suffered from this murrain; but although the disease was introduced in October, 1865, by cattle brought in for slaughter to feed the animals in the Zoological Gardens, London, where shortly afterwards the rinderpest broke out and destroyed a pair of bisons and three Italian cattle, it seems not to have spread beyond ruminant animals.

The cause of the disease is the next point to be considered. For my own part I believe that, like every other epidemic or epizootic disease, the cattle plague is caused by, or at least is connected with, some peculiar contamination, or "epidemic constitution of the atmosphere," the existence of which is established by its effects, though its nature is utterly unknown.

The Royal Commission appointed to inquire into the nature and origin of the cattle-plague in their last, *The Third Report*, deny the dependence of the disease on an "epidemic constitution of the atmosphere." And their opinion is followed by almost every writer I have consulted on the subject. But the Commission appear to me to bring forward no satisfactory proof that it is not connected with this cause. They say, "The way in which

the disease broke out and was destroyed in the Jardin d'Acclimatisation in Paris and over and over again in Aberdeenshire, its absence from Ireland, the manner in which it has spread in England and Scotland during the summer, autumn, and winter—all these facts are conclusive evidence against the assumption of an occult atmospheric condition, and in favour of its spread by multiplication in the bodies of living animals (p. 7). The weight of evidence appears to me, however, directly otherwise, and proves that, although most contagious, the disease is not propagated in this way only. If it were contagious it should spread with most rapidity where sanitary regulations are most neglected, and yet the Commissioners in their *Report of May, 1866*, admit that. In some of the worst cowsheds in London the plague has not yet penetrated; in some of the best it has swept the stock entirely away" (p. 8). At the Albert Veterinary College, where every precaution was used to ensure separation and prevent any contact, three animals kept twenty-five yards from some sick beasts, took the disease. The pestilential miasm, like all malaria, seems to love the earth, and seldom rises over elevated districts. Thus Mr. Williams has proved in the *Report of the Veterinary Department to the Privy Council* that the plague is Yorkshire adheres to the lowlands and valleys alone, and not a single case is recorded at the height of 1000 feet above the level of the sea (p. 35).

All epidemics have their season of rise, of progress, and of decline. After a certain period they tend naturally to become less "fatal in their attack and less contagious in their character, and as if the virulence of the poison had expended itself, they gradually wear away and disappear. Now, this law, which is little but an obvious truism, is, I think, overlooked by many of those who, because the cattle plague declines in any locality, ascribe this result wholly to the measures which have been adopted, and talk of the epizootic having been "stamped" out in such a place by the slaughter of all cattle supposed to have been infected with the rinderpest.

We hear a great deal said about "stamping out the cattle plague" by killing the infected cattle. In some districts we are told that the idea has been thus "stamped out," and great praise is given to the activity of the local executive. Now, heretical as the idea may seem, I have great doubts as to the possibility of eradicating any epidemic disease by killing those affected by it. The only reason which could justify the slaughter of all beasts attacked by rinderpest is, that the diseased animal is a centre of contagion, dispersing around a subtle and highly contagious animal poison. Therefore, if placed under treatment, which in successful cases averages three weeks, the plague-infected animal propagates the disease, and thus occasions a loss infinitely greater than any compensating advantage which the most successful treatment could confer. Those who reason in this way appear to me, however, to overlook the very important consideration that cattle plague, although highly contagious, does not depend on contagion alone, or even mainly for its diffusion, but is also spread by the "epidemic constitution of the air," to which no human barrier can oppose an obstacle. Therefore I think it would be more seemly to abandon the arrogant phrase I have alluded to, which supposes we have the power of averting the visitations of epidemic disease. But I fully admit that each plague-stricken beast becomes for the time a moving centre of contagion, and that consequently, in the absence of any successful plan of treatment, it may be wise, as well as justifiable, to destroy the infected animal to limit the amount of contagion as far as possible.

From the earliest times the relation between the weather and the sanitary condition of those exposed to its vicissitudes has been regarded as a subject of great interest. I have myself devoted considerable attention to this branch of medical inquiry, and have, in a work published two years ago, endeavoured to elucidate the nature of this connexion in relation to its influence to human health and disease. In this place, however, I had merely to examine

its connexion with epizootic disease in Ireland. But I may presume that almost every human epidemic, the history of which is recorded, was preceded or accompanied by some unusual atmospheric condition or intemperature of the seasons. The same observation holds good with regard to epidemic disease occurring in the lower animals. This intemperature is generally an unusual severity of the weather in winter. Thus in the ancient Irish annals so often quoted in this essay we find in nearly every instance that mortality among cattle, or *bo ar*, is preceded by some entry of the great severity of the foregoing winter. Thus the Four Masters record that the year 684, in which commenced "a great mortality on all animals in general, which lasted for the space of three years," was so intensely cold that "the sea between Ireland and Scotland was frozen over, so that there was a communication between on the ice." In the history of the English epizootics the same connexion between wet and cold and cattle disease may be observed; thus, in the winter of 1709 the weather was extremely severe, and it was followed by an epidemic in cattle in 1710. So also was the murrain of 1741 preceded by a hard winter, and the inelemt winter of 1767 seems to be similarly connected with the outbreak of the disease in the following spring. In the second *Report of the Royal Commissioners* we find that the cattle plague increased notably during the winter. Thus, up to the 9th of October, 1865, 11,300 cases had been reported, and on the 27th of January, 1866, the number had risen to 120,740.

With respect to treatment, my remarks shall be extremely brief, for now that it has been authoritatively decided that the only remedy is the poleaxe, any lengthened dissertation would be useless. In this epizootic nearly every method of cure recommended in former visitations, together with a few novel systems, were again resorted to and again failed. In truth, the disease seems little amenable to medicine, but yet there is reason to think that, had a more extended trial been given to it before resorting to the slaughter of all cattle affected with rinderpest, some more successful plan of treatment might have been discovered. In the *Report on the Origin, Propagation, and Treatment of the Cattle Plague, from June, 1865, to March 20, 1866*, we find the following table, showing the results of various plans adopted:—

| Treatment.          | Number treated. | Recovered. | per cent. |
|---------------------|-----------------|------------|-----------|
| Antiphlogistic      | 1389            | 27.5       | "         |
| Tonic and stimulant | 3842            | 25.9       | "         |
| Antiseptic          | 2970            | 25.4       | "         |
| Special             | 1507            | 25.8       | "         |
| Total               | 9708            | 26.3       |           |

If I were to recommend any plan of treatment I should do so on principles derived from the analogy which in my mind the rinderpest presents to the features of Irish typhus fever. I should advise the withholding of all solid food whatever throughout the entire course of the disease, the administration of a mild purgative in the early stage, the animal should be kept separated in a clean white-washed, warm but well ventilated shed, given as little medicine of any kind as possible unless it should be advisable to give stimulants in the latter stage. The chief reliance should in my mind be on the *vis medicatrix naturee*, and this might be supported by fluid nourishment, such as hot gruel or even hay water. With respect to disinfectants, numerous agents of this class have been suggested, as will be seen in the sequel, both in the present and in all past epidemics. The most valuable appears to be carbolic acid, but as this is seldom at hand in this country the most practical measures of this kind are the use of vessels of tar placed in each shed, and above all, cleanliness and white-washing. [To be continued.]

PAUPERISM in Ireland has much decreased. Last year the decrease was considerable, the daily average number of workhouse inmates having undergone a decrease of 3687, or 6.6 per cent., in comparison with the previous year.

## A CLINICAL LECTURE ON FEMORAL HERNIA.

By MAURICE H. COLLIS, M.B., F.R.C.S.,

SURGEON TO THE MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY, AND  
SOME TIME EXAMINER IN SURGERY TO THE QUEEN'S UNIVERSITY, ETC.

GENTLEMEN,—We have at present in the hospital some most interesting cases of femoral hernia. They interest us from their number, considerable in proportion to the time in which they arose; they further interest us by the fact that two out of the five patients are males, who are not usually subjects for femoral hernia; they are of further interest, inasmuch as in every case the hernia was reduced by Petit's operation, in which the sac is not opened; and, finally, they are a source of special gratification to us by the uniform success of the operation, and by the final recovery of the patients. Before I draw your attention to the patients who are specially under my care, it may be well to say a few words upon the subject of hernia in general, and upon the mode of operating for femoral hernia which I have adopted.

And first, as to hernia in general, a very great and important change has taken place in the treatment of strangulated hernia within the last thirty years; at least, it is only within this period that the improvement to which I allude has become at all general. Formerly when a portion of intestine became strangulated much valuable time was lost before an operation was decided upon. Purgatives had to be administered by mouth and rectum, the lowering effects of bleeding, tartar emetic and tobacco, were, one or other, or all, judged necessary, and prolonged attempts at reduction by taxis were repeated from time to time. Although by these means a small percentage of cases escaped operation, the remainder (a great majority) were placed under disadvantages which more than counterbalanced the benefit. In those days, according to statistics which I have compiled from various authors, the percentage of deaths, at the lowest computation, exceeded fifty per cent., and some writers, who refer to the earlier times, assert it to have been as high as two deaths in three. This great mortality was due to the combined influence of delay, of depression resulting from medicines, and of actual injury done to the intestine by the taxis. We now operate early in cases of strangulated hernia. A fair trial is given to remedies, but if they do not act promptly, we proceed to operate.

As to the mode of applying the taxis, it cannot be too frequently repeated that the object of the taxis is not to return the intestine but to empty it. Any one who studies the mechanism of hernia will at once perceive why this is so. When a knuckle of intestine comes down through a narrow opening, it gets spread out, filled with feculent matter, and gorged with blood, so that it quickly comes to bear no manner of proportion to the passage, through which, if at all, it is to get back into the abdomen. If direct pressure is made upon it when in this condition, this may flatten it a little, but cannot assist in returning it. Nay more, it increases the obstacle to return, which is produced by the disproportion between the size of the ring and the protruding intestine. The taxis is to be properly performed by laying the fingers all round the tumour, and by trying to compress the tumour by a movement which shall tend to approximate the tips of all the fingers. By this concentric movement of the fingers the intestine is gently compressed so as to unload it; if possible, first of its gaseous contents and then of its feculent, and perhaps also to diminish the amount of blood which circulates sluggishly and in a congested stream through the vessels of its walls. That this is so, all surgeons who have succeeded in returning a hernia know; first is felt and heard the gurgling passage of air from the intestine back into the abdomen, then by continued pressure the feces follow, and finally, the intestine is felt to slip up. Let this be borne in mind whenever taxis is used, and more especially when the stricture has been divided external to the sac.

Although chloroform is more especially useful in inguinal hernia, where the ring is more or less connected with muscle, its use is not to be despised in femoral. No doubt it cannot relax the ring, but it has great power over the abdominal muscles, and even over the muscular coat of the intestine. You have all seen how rigid the abdomen becomes when the bowel has been constricted for even a few hours. This rigidity yields under chloroform. I therefore advise you to chloroform your patient even in case of femoral hernia. In inguinal hernia this alone will often effect its reduction; and you should use it as a preliminary treatment before speaking of operation to your patient. In femoral, however, I have rarely found it of such distinct service until some at least of the constricting bands are divided; hence, I seek the patient's concurrence in the operation before I give chloroform, so that the one administration of the anæsthetic may suffice.

I now pass on to call your attention to Gay's operation. It is beautifully simple, and if you will take the pains to understand it, you will find it as safe as it is simple. You all know where Gimbernat's ligament lies; its position is further marked out for you by the tumour, to the upper and inner side of which it lies. Feel, then, for the neck of the tumour, the spot where you cannot get your fingers under it, where it feels as if part and parcel of the deep tissues of the thigh, and on its inner side make an incision through the skin long enough to admit easily the forefinger of your left hand—from three quarters of an inch to a full inch will do. The direction of this incision, as recommended by Mr. Gay, is nearly vertical, and such a line has been usually followed in all cases that I have either seen or operated on. One objection to it arises at a later period of the progress of the case, and to this I shall now allude, although somewhat out of place. The skin in this locality abounds in lymphatic vessels, running from the pubic and infra-pubic regions to the superficial chain of glands in the groin. Any vertical or oblique incision necessarily divides many of these small and thickly-packed tubes; hence arises frequently inflammation of the glands, which may run on, as we have lately seen, into either suppurating bubo, or may be the centre of a diffused suppuration. To avoid these consecutive accidents I propose, for the future, to make the preliminary incision parallel in direction to Poupart's ligament.

In whatever direction this incision be made it is merely to go through the skin; the finger-nail is now to be used to pick up on the side of the sac every constricting fibre which intervenes between the surface and Gimbernat's ligament. The number and direction of these bands will vary according to the length of time the hernia has existed. In recent hernia there will generally be found one tolerably well-marked superficial constriction, firm enough to be taken perhaps for Gimbernat's ligament. This is formed by that portion of the superficial fascia, known as the cribriform fascia, through which the saphena vein passes to the deep femoral, and through which also at this or some other opening the hernia often escapes. This is to be divided carefully with the hernia knife. The hernial sac may then be gently compressed to see if it will yield, or it may be slightly drawn down, if possible, by one finger in the wound.

It is quite possible that such a manœuvre may occasionally succeed. Care must be taken not to use too much force. In older hernie a succession of fibres and bands are found spread along the body or elongated neck of the sac. When all these are divided the true stricture is reached at Gimbernat's ligament; it lies wonderfully deep down, and it is to be remembered, the finger must be pushed on at right angles to the plane of the external wound, not being suffered to pass in any degree upwards, else the stricture will be missed, and the finger be lost in a region above and superficial to it. Once felt it cannot be mistaken; a touch of the knife divides it enough, it matters little whether upwards or inwards; a slight nick will do; gentle compression, with one finger in the wound and the others outside upon the sac, will now

empty the latter and complete the reduction. Cases will occur now and then in old herniæ where these measures are insufficient. The neck of the sac is thickened, the intestine is adherent, there is an hypertrophied mass of omentum, and you find even a free division of Gimbernat's ligament insufficient to get the hernia reduced. In such cases you should open the sac sufficiently to allow your finger in, and divide the constriction at the neck of the sac, if any exist. Large masses of omentum may be either broken up and returned, or in rare cases it may be needful to cut them away. The adherent intestine will be carefully separated from the sac and returned; in rare cases this is impossible, and you must be content to divide all constrictions freely (as is known by your being able to empty the gut), and to leave it *in situ*. As regards stricture by the neck of the sac, an old hand may even venture to nick the outside of the sac with great care, and so may avoid the necessity of opening it, but I do not advise a beginner to try this delicate and dangerous manœuvre.

You may hear many objections raised to Gay's operation; they have been refuted over and over again. Some of them arise from prejudice, others really from ignorance. The former will yield as surgeons become impressed with the superior safety of the operation: of the latter I give you but one example. It has been said over and over again, that you run the risk of returning the hernia strangulated *en bloc*—that is, that you are liable to send back the sac, with its contents in one mass, still strangulated by the constriction of the neck of the sac. This really silly objection ought not to pass the lips of any one who knows how to use the taxis aright. Such an accident I never saw, nor can I conceive it to occur in the hands of any one who knows how to use the taxis properly. Gentle concentric compression, and not direct backward pressure, as I before said, is the proper method, and if this is remembered the return of the hernia *en bloc* cannot occur.

I shall now read the notes of two cases taken for me by Mr. George Roe Carter:—

STRANGULATED FEMORAL HERNIA OPERATED ON BY MR. COLLIS.

Ann Baker, æt. 50, or more, not married, was admitted into hospital on the 1st May, with a strangulated femoral hernia on the right side. The patient stated that on the 28th April, when carrying a bundle of clothes on her back, she suddenly got a pain in her bowels; this became very violent, and on her return home she was obliged to go to bed; vomiting came on soon after. She had no previous rupture, and first noticed the swelling on that night. Dr. C. F. Moore of Peter-street Dispensary was sent for; he ordered her a dose of castor oil, which she vomited. She had repeated attacks of vomiting on the 29th and 30th ultimo, but none on the day she was admitted. Dr. Moore made efforts to reduce the hernia at different times, but finding it impossible he had her removed to hospital. Mr. Collis used a reasonable amount of force in trying to reduce the tumour, but finding the stricture very tight, he did not try the taxis for more than a few minutes. He at once decided on operating, which was done about half an hour after the patient was admitted. Having put the patient under chloroform he performed "Gay's operation" after the usual manner; there were two strictures, one superficial, and the other deep, at Gimbernat's ligament, which he divided, and returned the contents of the sac with the greatest facility; the wound was brought together by a horse-hair suture and a pad of lint, and bandage applied; the patient was removed to bed, and ordered a draught containing twenty-five drops of Battley and some wine. Five p.m. (three hours after the operation), the patient appears to be going on favourably; pulse 120.

May 2nd: The patient is going on well; slept pretty well during the night; pulse 120; tongue moist. Ordered wine  $\mathfrak{z}iv.$ , and beef-tea, and the following draught:

$\mathfrak{R}$  Olei ricini,  $\mathfrak{z}ss.$

Tincturæ sennæ comp.  $\mathfrak{z}ii.$

Aquæ menthæ piperitæ ad  $\mathfrak{z}ii.$  M. Fiat haustus.

3rd: The patient had a pretty good night; complains of headache and thirst; pulse 112; beef-tea and wine continued. Ordered an opiate at night, and a bread-and-water poultice to the wound; bowels moved on yesterday.

4th: Did not sleep so well as previous night, but feels better, the superficial glands in the groin are somewhat inflamed and tender to the touch; bread-and-water poultice continued. She appears rather low. Ordered wine  $\mathfrak{z}viii.$ , and a pill containing one grain of opium; pulse 108.

5th: Slept well during the night; looks better; wound more healthy; the inflammation of the glands has greatly subsided; pulse 90; beef tea and wine continued. Ordered  $\mathfrak{R}$  Olei ricini,  $\mathfrak{z}ss.$

6th: The patient is going on favourably, appears much better; had a good night; pulse 90; tongue moist and clean; nourishment continued.

7th: Continues to improve; the wound assumes a healthy appearance; pulse 88.

9th: The patient is considerably better, able to sit up in the bed; pulse 84; tongue clean.

12th: She continues to go on well; the wound is healing nicely; the inflammation of the glands has altogether disappeared. Wine and beef-tea continued; pulse 88; tongue clean.

16th: The patient is much improved; feels considerably stronger; the wound is almost healed.

19th: The patient having got on a truss was able to be up to-day. The patient left hospital soon after with the wound almost healed and protected by a truss. Her general health was also greatly improved. She had some bad symptoms for a few days after the operation, which was only natural to expect from the length of time the hernia was strangulated.

CASE OF STRANGULATED FEMORAL HERNIA OPERATED ON BY MR. COLLIS.

John Beahan, ætat. 43, dairyman, brought into hospital by Dr. O'Dwyer, on the 3rd of May. The patient has had a hernia on his right side for the last four years, which he could always put back until the morning he came into hospital, but never wore a truss. At six a.m. on the above date, the hernia came down; the patient finding he could not put it back, went to Dr. O'Dwyer of Camden-street, who also tried to return it; finding that moderate taxis did not avail, Dr. O'Dwyer brought him to this hospital. The patient complained of pain in the bowels, but did not vomit. Mr. Collis examined him and found the stricture to be very tight. On consultation he decided on operating, and at eleven a.m. having put the patient under chloroform, assisted by his colleagues, he performed "Gay's operation". Having divided two or three superficial strictures, he came down on Gimbernat's ligament, and returned the contents of the sac. The wound was brought together by a hemp suture and a pad of lint, and bandage applied. The patient was removed to bed, and ordered Battley gttss. xxv., and some beef-tea in the afternoon. Six p.m.: The patient is going on well; pulse 90.

May 4th: Slept well during the night; going on favourably; bowels not moved since the operation; pulse 80; beef-tea continued; no wine ordered.

5th: The patient is getting on well; had a good night; pulse 88; tongue moist and clean; beef-tea continued. Ordered:

$\mathfrak{R}$  Olei ricini,  $\mathfrak{z}vi.$

Tincturæ sennæ comp.,  $\mathfrak{z}ii.$

Aquæ cinnamomi  $\mathfrak{z}i.$  M. Fiat haustus.

6th: The patient is going on favourably; had a good night; his bowels were moved to-day; pulse 90; his tongue is clean; the wound assumes a healthy appearance; bandage and pad removed; beef-tea continued.

8th: He is going on well; has not had a bad symptom since the operation; pulse 80; tongue moist and clean.

10th: Continues to improve; pulse 80; ordered the following draught:

$\mathfrak{R}$  Olei ricini,  $\mathfrak{z}vi.$

Tinct. sennæ comp.  $\mathfrak{z}ii.$

Aquæ cinnamomi,  $\mathfrak{z}i.$  M. Fiat haustus.

12th: The patient continues to improve; the wound is healing nicely.

15th: The patient left hospital to-day with the wound almost healed, and wearing a truss; thus in eleven days the patient was cured of his dangerous malady without one bad symptom since the operation.

## Hospital Reports.

CITY OF LONDON HOSPITAL FOR DISEASES  
OF THE CHEST,

VICTORIA PARK.

CASES TREATED WITH HYPOPHOSPHITES  
OF SODA AND LIME.

(Under the care of Dr. THOROWGOOD.)

*Case 1.*—Elizabeth R., æt. 38, came under observation September 14th, 1865. Patient has just returned from Sydney. While living there she was taken, about nine months ago, with severe cough, copious expectoration, and great general debility, all these symptoms coming on gradually, and with increasing severity.

The physician who was called in prescribed citrate of iron, applied tincture of iodine over the right side of the chest, and told the patient she had tubercles forming in her right lung.

Shortly after she set sail for England, and was soon conscious of great benefit from exposure to the sea air (the climate of Sydney she described as very changeable, and ill-adapted for such a case as hers), so that by the time she reached England she was in much better health, notwithstanding one or two attacks of hæmoptysis.

*Present State* (September 14, 1865).—Pale, but not thin. During the few weeks she has been in London has had much return of cough, with thick expectoration and much dyspnœa; pulse 104; tongue clean.

*Physical Signs.*—No marked dulness. Breath sound feeble under left clavicle; very harsh and tubular under right clavicle and at right supra-spinous fossa; often much pain on this side of the chest.

R. Sodæ hypophosphit. gr. v.  
Tr. camph. co. ℥x.  
Aq. camph. ℥j.  
M. Ft. hst. ter die sum.  
Ol. morrh. ℥ij. ter die.

September 19th: Much less cough and spit; pulse 80; cannot take the cod-liver oil, as it causes heartburn. Respiration on right side not so harsh as it was.

She continued the above mixture till October 10th, when it was changed to one of vin. ipecac, with tr. opii with mucilage. This agreed very well, but she preferred the hypophosphite, and this was therefore again given till early in November, when she left town, the cough and expectoration being much diminished, the general strength greatly improved, and the respiration in the right lung less harsh and quite painless; she was able also now to take some cod-liver oil.

*Case 2.*—Ann B., æt. 16, living in Whitechapel, seen June 2, 1864.

*Present State.*—Pale, thin, and wasted; been ill twelve months, and had frequent attacks of hæmoptysis; cough very severe, with copious expectoration; pulse 120.

*Physical Signs.*—Right front quite dull and full of crepitation; left, deficient expansion, and respiration very blowing.

This patient got for a time five grains of the hypophosphite of soda in infusion of calumba, and also cod-liver oil. Under this treatment her appetite improved, but the pulse did not fall and the cough was severe, so that a change was made to one or two expectorant and opiate mixtures, with the effect of greatly impairing the

appetite without sensibly checking the cough and expectoration. Eventually she found five grains of hypophosphite of lime in infusion of calumba, cod-liver oil, and a morphia pill at bedtime, the treatment that gave her most relief. The physical signs seemed in no way to increase, and she held on fairly till one intensely cold day in January, 1866, when she suddenly sunk into a state of great collapse, and in a few hours died.

*Case 3.*—J. F., a clerk, seen January 12, 1865. Looks pale and rather thin, and has been ill with a cough and blood-stained sputa for twelve months.

Pulse 100; appetite bad; has to work hard, and is much confined indoors; tongue coated.

*Physical Signs.*—Left chest very dull, with humid crackling at upper part; slight râle heard also at right infra-clavicular region, but resonance here is good.

R. Sodæ hypophosphit. gr. v.  
Sodæ bicarb. gr. x.  
Infus. calumbæ, ℥j.  
M. Ft. hst. ter die sum.  
Ol. morrh. ℥ij. ter die.

January 19th: Two days after last visit to hospital coughed up half a pint of blood and phlegm. To-day feeling better; less cough; less spit; pulse 84. The percussion note seems rather clearer over left chest, but no good breathing to be heard.

Begs to be let off the oil, as it makes him feel very sick. Omit oil and continue hypophosphite.

February 9th: Less nausea; less expectoration; appetite much better; left side clearer, and dry creaking is heard more than the humid crackling of a former date.

Soon after this he was let go at own request.

November 30th, 1865: Came again, looking fearfully ill and pale; constant cough and copious spit, but no blood; left lung full of humid crackling, and dull on percussion; right in fair condition.

This time he got syrup of iodide of iron, cod-liver oil, and a morphia pill at bedtime.

December 28th: Feels better, but expectoration and cough increase greatly, and suspicious sounds are heard in the upper part of the right lung, while in left large humid crackling exists in increased amount. Pulse 88. Thinks the oil does not suit him. He had a quinine mixture given him, and was not seen again till February 15th, 1866, when he came in a worse state than ever. Tongue dry and red; much sickness, left lung full of moist sounds, and respiration in right extremely feeble. Ordered five grains of hypophosphite of soda in camphor water thrice daily, and five grains of carbonate of iron pill after breakfast and dinner.

22nd: Feels much better; able to do some work, and begs to be allowed medicine for a fortnight.

March 8th: Cough much less; appetite better, though at times he vomits his meals; less moist sound in left lung. Ordered an alkaline tonic two hours after meals.

22nd: Less cough; less spit; complains of the time he loses in coming to hospital, and thinks now he shall do very well.—Not seen again.

### REMARKS.

These three cases exhibit pretty well-marked instances of confirmed phthisis.

No. 1 had been treated with citrate of iron and the external application of iodine, but it seems no relief was experienced till she was out at sea, and when the same symptoms returned after she had been a short time in London, she found the hypophosphite of soda to give more relief than anything she had ever tried.

Few will dispute the genuine nature of the disease in No. 2, and of the variety of medicines used none seemed so valued by the patient as the hypophosphite, given in a very simple form. Probably had this patient been able to leave Whitechapel, and go to a warm and healthy place for the winter, she would yet be alive.

No. 3 was one who worked hard, and in a close atmosphere. He sorely grudged the time spent in attending the hospital, but yet even with his irregular attendance he

managed to reap very decided benefit from the use of the hypophosphite of soda.

Thus we see that these hypophosphites, like many other medicines, have their use and sphere of action in checking the progress of phthisis. To cry them up as specifics in all cases is a grievous error, likely to lead only to the abuse and discredit of the medicines, for there are cases of true phthisis in which they have no appreciable action, while iron, nitric acid, or possibly zinc, will have a great effect in removing symptoms and doing good to the patient. He is likely to prove the best physician who, while eschewing the title of specific hunter, at the same time observes cases in their individual peculiarities and differences, and giving medicines simply and uncomplicated by admixture with a host of other well-meant drugs, notes carefully under what circumstances he succeeds, and also not less carefully and scrupulously under what conditions failure only results from his efforts.

### METROPOLITAN FREE HOSPITAL.

#### WHOOPIING-COUGH CURED BY HYPODERMIC INJECTIONS.

(Under the care of Dr. BEIGEL.)

ANN WILSON, three years old, began to cough at the beginning of January, 1866, the cough becoming more and more intense until it ended in severe whooping-cough. Admitted to hospital January 21. She is worse at night, and attacks are so frequent that she has little rest. Each attack ends in vomiting a quantity of slime. She is a well-built child, chest fully developed. On right side some râles, but nothing else abnormal on auscultation and percussion. Appetite fair; bowels rather costive; one-twelfth of a grain of acetate of morphia by subcutaneous injection. The mother had not left the consulting-room many minutes when she returned very much alarmed, because the child seemed "lifeless;" it was soundly sleeping. In the evening the mother's fears became more urgent, because the child did not wake, but she reported that it breathed easily. Advised to let it sleep without disturbance.

27th: Reported that child slept till next morning; on waking it coughed still, but without hooping; injection repeated.

31st: Slept after last injection eight hours; cough, extremely slight, about three times during the night; no vomiting after the cough; appetite much better. From this time the child recovered.

Out of five cases of ague successfully treated by Dr. Beigel by the hypodermic method, we report the following:

Harriet Franklin, æt. 30, married, never before ill. In August, 1865, went with her husband to Harveston, and there was attacked with fever, called by the doctor in the town marsh fever. It had a tertian type and lasted three weeks, but yielded to the use of quinine. In the following September it returned, but was quartan; lasted two months, and was again stopped by quinine. The patient remained well up to January 14th, 1866, when the attack again seized her. Returns every day at noon, beginning with pain in the spinal column, followed by very intense shiverings which are succeeded by great heat, and this in turn by profuse perspiration. The fit occupied about two hours.

17th: Admitted out-patient, pale and ill-nourished; she is now in the febrile paroxysm; respiration accelerated; pulse 128; spleen much enlarged; injected a quarter of a grain of acetate of morphia.

18th: Sick nearly the whole night; attack at noon as usual; injection repeated.

19th: Attack occurred at eleven o'clock to-day, but was much slighter; slept much better the previous nights; injection repeated.

21st: Attack recurred early in the morning, but was very slight; injection repeated. From this time there was no recurrence of the attacks.

### MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

#### CASES UNDER THE CARE OF MR. PORTER,

SENIOR SURGEON TO THE HOSPITAL.

[Reported by ARTHUR WYNNE FOOT, M.D.]

(Continued from page 35.)

#### COLLES' FRACTURE OF THE RADIUS TREATED WITH GORDON'S APPARATUS.

Case 30.—A middle-aged woman fell over a piece of wood while pursuing a pig which had been trespassing in her garden; putting out her hands to save herself, she fell to the ground, and the left radius was broken across within an inch of the wrist-joint. Very soon after the occurrence the fracture was put up according to the method called Nélaton's, with a curved dorsal splint maintaining the hand in a state of adduction. This position and splint gave her great pain, and was removed in a short time by Mr. Porter, who applied the splints and pads recommended by Professor Gordon of Belfast. The displacement having been reduced, the forearm was laid upon the boat-shaped splint, in the prone position, the hand hanging over, and the bevelled portion of the radial pad brought exactly under the seat of fracture, the dorsal pad and the second splint extending from the upper end and back part of the forearm to the metacarpus was now applied, and the whole bound together by two straps with buckles. The woman found immediate relief from pain after her forearm had been put up in this manner. In the thirty-ninth volume of the *Dublin Quarterly Journal*, Mr. Porter has given the results of seven cases of Colles' fracture which he had treated with Gordon's splints, and his experience since then has confirmed him in his opinion of the superior advantages of this method of treating these fractures. He sums up the advantages of this method thus:—It is more comfortable to the patient than any other; it restores the natural concavity of the radius and produces a straighter limb; perfect use of the forearm is obtained sooner by it than by any other method; the manner of binding with two straps is lighter and more manageable than the application of rollers.

#### EPITHELIAL CANCER IN THE LOWER LIP—EXCISION.

Case 31.—During the present month a tall healthy-looking man applied to Mr. Porter about a sore on his lip. On examination it proved to be an epithelial ulcer, as yet superficial, occupying the middle portion of the lip. It originated from a very trivial pimple first observed two years before the present time. There was no glandular enlargement, nor any irritation of the follicles on the mucous surface of the lip. He had been an habitual smoker of the pipe, but the central position of the ulcer did not make it very probable that this habit had any direct relation to the disease. A more important fact was that his father and his father's brother had suffered from "cancer in the lip." The former died of it, "because he had neglected it and it spread;" his uncle had the affected portion of his lip removed, and the disease did not recur. Profiting by their experience the nephew applied in very good time, being most anxious to have the sore at once removed. The ether spray was applied to the part by Mr. Smyly from a double-jetted instrument; Mr. Porter took a horizontal slice off the free border of the lip, and then brought the mucous and cutaneous surfaces in apposition by four points of silver wire suture. A propensity to the epithelial variety of cancer is not so often observed among related persons as one to other varieties of cancer is, so that its occurrence in three members of a family is deserving of record, the more so, because this form of cancer being more than any other attributed rather to the influence of external agencies than to a cancerous crisis

or diathesis, an hereditary predisposition is not, *a priori*, to be so much expected.

#### HYDROCELE OF THE TUNICA VAGINALIS TESTIS—PALLIATIVE TREATMENT.

*Case 32.*—A man, 30 years of age, applied to Mr. Porter with a collection of fluid in the tunica vaginalis testis on the right side, of seven years' existence. He was not aware of any cause for this accumulation of fluid; he had not received any injury, nor were the veins of the leg or spermatic cord in a varicose condition. The hydrocele had been emptied by tapping on nine previous occasions, and had now again assumed a large size, the penis being almost buried in the tumour and directed towards the left side. Mr. Porter pointed out the diagnostic marks between hydrocele of the tunica vaginalis and those affections in the neighbourhood of the organs of generation, with which this complaint may be confounded, and observed upon the application of the translucent test, which in this particular instance was very satisfactory; that this means of diagnosis was not unfrequently frustrated in old hydroceles by a preternatural thickness of the tunica vaginalis, or by opacity of the liquid of the hydrocele from admixture with blood, or from other causes. Not being able to prevail upon the man to submit to an operation for the radical cure, Mr. Porter tapped the tumour, and drew off twenty-two ounces of a clear lemon-coloured albuminous fluid, possessing the usual resemblances to the serum of the blood, which the fluid in simple hydrocele generally presents.

#### RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

##### DR. LYONS'S CLINIQUE.

#### ARACHNITIS SITUATED AT THE BASE OF THE BRAIN.

Two further cases of this formidable affection will be worthy of notice. The first has been already partially alluded to on a former occasion.

*Case 1.*—A boy, aged 12, previously in the enjoyment of excellent health, went to bathe on Sunday, June 3, 1866. He remained for some time in the water, and on the next day was seized with severe pain in the head, rigidity of the deep muscles of the neck, retraction of the head, and inability to draw it forward, or perform the nodding motions without extreme pain, and beyond a certain angle no force, which it was safe to apply, could succeed in causing the head to nod downwards and forwards. As in the previously recorded instances of this disease the pulse varied much in the progress of this case. At first there was a certain amount of pyrexial action, with hot skin, foul tongue, and pulse at and above 100. A few days subsequently the pulse sank to 80, to rise again some few days afterwards to a rate of 100 per minute. It is worthy of note that the rate of the pulse and the amount of cerebral pain complained of appeared to bear no direct relation to each other. The pain was constant for several days and then remitted, to recur after a variable interval with almost undiminished force. Very slight dilatation of the pupils was observable for about three or four days successively, but the rigidity of the deep cervical muscles continued in a marked degree for at least three weeks. A rather curious play of antagonistic muscular force was exemplified in the attempts to nod the head forward. The patient, in the effort to accomplish this action, seemed to bring into action, partly voluntarily and partly involuntarily, all the muscles which assist in flexing the head on the neck and the head and neck on the trunk, and conspicuous amongst these latter were the contractions of the *platysma myoides*, the fibres of which showed very visibly through the skin over the clavicles and infra-clavicular regions, contracting in radiating cord-like masses, and thus displaying the anatomical distribution of its muscular

fasciculi in a manner but rarely so well demonstrated in the dissecting-room.

Mercury, leeches to the head, and blisters were employed in succession, and with but variable and doubtful result. The relief from the application of leeches was by no means so marked as in one of the cases recently recorded, in which the patient himself *craved* the application of the leech on each accession of pain. In the case under consideration the little patient had a dread of the application of a leech, said it *caused* the pain, and attempted to conceal the accession of pain to avoid the application of the dreaded leech.

After a very protracted period (thirty days) convalescence began to be slowly established. Extreme emaciation had taken place in this case, and under the impression, considering the age and condition of the patient, that tubercular deposit might be formed in the membranes of the brain or other situation, cod-liver oil was administered.

*Case 2.*—The patient, a man previously in good health, aged 55, after exposure to cold, was seized with anomalous symptoms, vomiting, some pain in the head, much depression, hebetude, and indistinct pyrexia. The pulse was found to be but 60, when the patient was first seen; urine and fæces were being passed involuntarily; the patient was sweating profusely, lay in a dull stupid condition, from which, when forcibly shaken, he could be partially roused, and induced to put out the tongue, give short, surly, but coherent answers, but he relapsed immediately; no paralytic condition existed, save that the pupils were largely dilated and insensible to light. The head was shaved and extensively blistered with the acetum lyttæ, ten grains of calomel were placed on the tongue, and prompt measures were taken to induce mercurial action in the system. A slight rally appeared to take place on the following day, the patient was more readily roused, and could with less difficulty be got to answer, put out the tongue, &c., but the pupils remained dilated and insensible. On the subsequent day the pulse rose suddenly to 140, all the symptoms of depression and compression became aggravated, a tympanitic state of the abdomen was superadded, and the patient rapidly sank, and death took place about the seventh day from the first seizure.

Dr. Lyons remarked on the great importance of early diagnosis, and the prompt employment of very active measures in these somewhat obscure cases. He regards the condition of the pupil as the cardinal point in the diagnosis and prognosis.

These cases may be distinguished by the early occurrence of depression, with dulness or hebetude, but the capacity for being partially roused to consciousness remains, and coherent answers can be extracted from the patient, after which he relapses.

Violent pain, deep-seated in the head, is complained of in some instances. Paralytic phenomena are not to be looked for until the close of the case, when relaxation of the sphincters, immobility, and true coma may be present. Dilatation of the pupil is observable sometimes at an early period, and is then persistent until death, or in some cases until convalescence begins to be unmistakably established. It constitutes the most important, and, so to speak, the cardinal phenomenon of the case, in the absence of other paralytic conditions. It is dependent, as before explained, and as shown by the result of Dr. Lyons's post-mortem examinations on gelatiniform exudation within the circle of Willis, sufficient in amount to compress the delicate and ill-protected filaments of the sympathetic, and so to paralyse the ciliary supply from the lenticular ganglion, while the amount of effusion is inadequate to interfere by compression with the functions of the second, third, fourth, fifth, or sixth pairs of nerves, by reason of the greater consistence and power of resistance of their firmer neurilemma.

The phenomena of rigidity of the neck, of gastric irritation, and vomiting, and the tendency to rapid and extreme wasting of the tissues where the case lasts for any lengthened period, would seem to be referrible, in Dr. Lyons's

opinion, to the pressure and consequent irritation exercised by the gelatiniform exudation on the roots of the par vagum, and on the cranial plexuses of the sympathetic. The variable states of the circulation may be fairly attributable to the same lesion.

It is worthy of remark that these cases present a high mortality. Active depletion of the head by repeated relays of leeches, and by continuous vesication, with the free use of mercury, appear to be the means which offers the best prospect of dealing successfully with these cases. The obstinate and, in some instances, complete resistance to the specific action of mercury, has been already commented on.

## Proceedings of Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 12TH, 1866.

Dr. P. BLACK, Vice-President, in the Chair.

#### ON ATROPHY OR DEGENERATION OF THE MUSCLES OF THE UPPER AND LOWER EXTREMITIES FROM DISEASE OF THE SPINAL CORD.

By GEORGE LEWIS COOPER, F.R.C.S.,  
SURGEON TO THE BLOOMSBURY DISPENSARY.

J. J.—, aged 41 years, married, but his wife had no family; was much exposed to the weather in his daily occupation, at the same time had been a man of intemperate habits, and the subject of a long chronic cough. He was admitted under the care of the author at the Bloomsbury Dispensary on Feb. 14th, and died on the 26th. He suffered from complete paralysis of the upper and lower extremities, with atrophy of the muscles of these parts. The symptoms were slow, but progressive. They commenced in the hands and feet, and extended to the arms and legs, and ended in total paralysis. His cough was severe, with purulent expectation, to the time of his death, which took place on Feb. 26th. The post-mortem showed much distension of the coverings of the cord from fluid, with congestion of the pia mater in the cervical region, and considerable softening in the substance of the white columns. At the commencement of the lower third in the dorsal region the central grey substance contained a large dilated vessel on each side, surrounded by extravasated blood-globules; and the extremities of the posterior cornua were highly vascular, as also in certain parts of the grey substance there were patches of extravasated blood.

Dr. PAVY exhibited a patient from Guy's Hospital, the subject of Vitiligoidea Plana et Tuberosa. He remarked that this disease had been described by Drs. Addison and Gull in the Guy's Hospital Reports for 1851. In their communication they stated that the affection they were describing occurred either as tubercles, varying from the size of a pin's head to that of a large pea, isolated or confluent (vitiligoidea tuberosa); or, secondly, as yellowish patches of irregular outline, slightly elevated and with but little hardness (vitiligoidea plana). Either of these forms, they further stated, might occur separately, or the two might be combined in the one individual. The case before the fellows of the Society was an exceedingly well-marked one, and one in which the combination of the two forms occurred. The patient, a female, aged 39, three years ago became the subject of jaundice, which lasted for ten months. She was then free from it for about two months. It afterwards reappeared, and had continued up to the present time. About a year and a half ago she experienced a sensation of great itching and stinging in her skin, and after this the eruption that now existed began to appear, and gradually reached its present state. It was not so perceptible by night, but she was pretty deeply jaundiced of an olive colour by day; and in association with the jaundice it was to be remarked that a large and tender swelling, evidently connected with the liver, was to be seen in the right hypochondriac region. Completely

encircling each eye, and extending for a space of from half to three-quarters of an inch in breadth, was a patch of an opaque yellowish colour, and slightly elevated above the surrounding skin. Upon the ears there were a number of tubercles, looking certainly to the eye like sebaceous tumours. Similar tubercles also existed upon the backs of the hands and arms, and also on the back and nates. Upon the palms of the hands and palmar aspect of the fingers there was a patchy and diffused cream-coloured deposit in the skin. This disease, Dr. Pavy observed, had been recently considered by some as a disease of a sebaceous character. It was so regarded in Hebra's work on skin diseases, which is being translated by Dr. Fagge for the Sydenham Society. In Neligan's work, published in 1866, it had been spoken of as a form of acne, and called "stearrhœa flavescens." It was a point of interest, Dr. Pavy considered, to determine the precise nature of the affection, and he had had a tubercle removed from the back of the little finger for microscopic examination. The deposit pervaded the true skin and occurred in little nodular masses beneath. These were exceedingly tough, and consisted of fibrous tissue. On being squeezed between the forceps an opalescent juice exuded, which was found to contain a large number of fat-granules. The cuticle was not involved in the affection. Independently of the result of minute examination, against its being a sebaceous disease was the fact that it occurred, and in a marked manner, on the palmar aspect of the hands where no sebaceous glands existed. Dr. Pavy also exhibited another patient from Guy's Hospital suffering likewise from a peculiar form of skin disease. The subject of it was a feeble, sickly-looking woman, twenty-five years of age. She belonged to a family in which there was a history of both scrofula and carcinoma. Upon the fingers and hands were some scar-like looking spots of a bluish-white colour, which had been gradually appearing since March last. There were also spots of a somewhat similar character on the outer side of the anus. They came without any previous sore or ulceration. They might be said also to look as though the skin had been seared by the application of a hot iron. Dr. Pavy was open to the suggestions of the fellows present, but he had regarded the case himself as an early stage of the disease which had been described by Dr. Addison in the thirty-seventh volume of the "Medico-Chirurgical Transactions," under the name of "true keloid." This now went by the name of "keloid of Addison" in contradistinction to the keloid which had been described by Alibert, and which was altogether a different disease, consisting as it did of raised tumours with claw-like prolongations instead of cicatrix-looking spots.

## Abstracts of the Scientific Societies.

ZOOLOGICAL.—June 26.—Dr. E. Hamilton in the chair.—The Secretary called the attention of the meeting to a fine specimen of the Californian vulture (*Cathartes Californianus*, Shaw) lately received in the Society's Gardens.—A communication was read from Mr. G. Krefft, containing "Descriptions of New Species of Australian Snakes, of the Genus *Hoplocephalus*."—A communication was read from Dr. J. C. Cox of Sydney, containing characters of six new Australian Land Shells.—Mr. T. J. Moore communicated some notes on the habitat of *Chauna Derbiana*, which appeared to be the littoral of New Granada, and not Central America, as had been previously supposed.—A paper was read, by Mr. H. Adams, "On the Shells collected by Mr. S. W. Baker, during his recent Explorations in Central Africa." Two species of *Unio* contained in Mr. Baker's collection were considered by Mr. Adams to be new to science and described under the names *U. Bakeri* and *U. acuminatus*.—Mr. Frazer exhibited and made remarks on a pair of Horns of the Philippine Deer (*Cervus mariannus*, Desm.)—Mr. H. E. Dresser read some notes on the nesting of the Booted Eagle (*Aquila*

*pennata*), and exhibited specimens of the eggs of this bird recently obtained by himself in Central Spain.—Mr. Blyth exhibited some pairs of Horns of different varieties of the African Buffalo (*Bubalus Caffer*), and pointed out the distinctions between the Central African and Southern forms of this species.

ENTOMOLOGICAL.—July 2.—Sir. J. Lubbock, Bart., President, in the chair.—The Hon. T. De Grey, M.P., and C. Ward, Esq., of Halifax, were elected Members.—Mr. Stainton exhibited a head of *Typha latifolia*, for the purpose of showing the mode of feeding of the larva of *Laverna phragmitella*; also, specimens of a *Gelechia*, very similar to *G. leucomelanella*, bred from galls formed on *Gypsophila saxifraga*, and found at Mentone.—Mr. Bond exhibited a specimen of *Dianthæcia cæsia* and a Phycita, probably new, both captured in the Isle of Man, by Mr. Hopley; also specimens of *Lesia philanthiformis*, bred from pupæ sent to him by Mr. Greening, from the Isle of Man.—Mr. Edwin Shepherd produced a specimen of *Dianthæcia cæsia* from Bentley's collection, supposed to have been captured many years ago in Yorkshire.—Mr. Edward Saunders exhibited a collection of Mexican butterflies, amongst which was a gynandromorphous *Pieris Euterpe*.—Mr. Pascoe called attention to an extract from Von Tschudi's "Thierleben der Alpenwelt," and to a paper, by Mr. Albert Müller, in the last number of the *Zoologist*, with reference to insects at considerable elevations in Alpine regions settling on and sinking into the snow through the radiation of heat from their bodies, confirming some observations of Mr. Pascoe communicated to a former meeting of the Society. A discussion ensued, in which Professors Westwood and Brayley took part.—The President directed attention to an article in the *Comptes Rendus* for the 4th of June, 1866, by M. Balbiani, in which the author, as the result of observations of his own, advanced a theory that the Aphides are true hermaphrodites.—Mr. Stainton mentioned that much injury had been done to the rye in the neighbourhood of St. Etienne which he believed was caused by the larva of *Ochsenheimeria taurella*.—Mr. Stevens exhibited *Dicranoccephala Wallichii* from Northern India, and *D. Bowringii*, from Southern China.—The Rev. Douglas Timins communicated notes on larvæ of *Charaxes Jasius* and *Melitæa Provincialis*.

ROYAL INSTITUTION.—May 4.—Sir Henry Holland, President, in the chair.—"On Recent Progress in the History of proposed Substitutes for Gunpowder," by Prof. F. A. Abel.

May 25.—Sir H. Holland, Bart., President, in the chair.—"On the Shooting-stars of the Years 1865-6, and on the Probability of the Cosmical Theory of their Origin," by Mr. A. S. Herschel.

June 1.—Sir H. Holland, Bart., President, in the chair.—"On the Opalescence of the Atmosphere," by Mr. H. E. Roscoe.

June 15.—"Experiments on the Vibrations of Strings," by Prof. J. Tyndall.

July 2.—Sir H. Holland, Bart., President, in the chair.—The Duke of Edinburgh was elected an Honorary Member; R. Kockerton, Esq., was elected a Member.

SOCIETY OF ARTS.—June 27.—W. Hawes, Esq., Chairman of the Council, in the chair.—The Secretary read the Annual Report of the Council.—Silver Medals have been awarded by the Council as follows:—To Mr. J. C. Morton, for his paper "On London Milk;" to Mr. T. Gray, for his paper "On Modern Legislation in regard to the Construction and Equipment of Steam-ships;" to Dr. J. L. W. Thudichum, for his paper, "On the Diseases of Meat as affecting the Health of the People;" and to the Hon. C. G. Duffy, for his paper "On some Popular Errors concerning Australia."

PRODUCE OF MERCURY.—The produce of the New Almaden (Spain) mines for the last ten years has averaged about two thousand five hundred flasks, of seventy-six and one-half pounds each, of mercury per month.

## THE LATE POISONING CASE.

APROPOS of a recent poisoning case, the *Court Circular* remarks:—

Now, a man entrusted with the lives of the public is, to all intents and purposes, a public man. His actions are open to criticism and liable to praise or censure as their merits may justify. And it is right that it should be so. A surgeon or physician is bound to bring a certain amount of skill to the performance of his duties; and if he is not what he represents himself to be, he is a pretender. To the encroachments of such men the medical profession is especially liable. Every other profession—the church, the law, the army, and navy—is guarded against intruders, save this; and yet this is the most important of all to be kept sacred. A great deal of fuss is often being heard about medical bills before Parliament and elsewhere, but to this moment there is no efficient protection against ignorance and quackery. The self-styled physician may prescribe, and the druggist's errand-boy may dispense; if either kill his victim, the law, which ought to punish severely, as it would for a criminal offence of grave magnitude, is practically powerless. The quack escapes and the public suffers.

In the particular case which gives rise to these remarks the druggist should have paused for further instructions before he made up such a prescription. Four grains of morphia ordered in a draught by a person who, on his own showing, could write neither Latin nor English correctly, was assuredly enough to make any well-qualified druggist consider twice before he sent such a dose out of his shop. Yet, so far from the shopman who prepared this prescription feeling any doubt about it, he openly asserted on oath before the coroner that he frequently administered as much as twenty grains of morphia and he felt no hesitation in doing so.

Now, if the law were what it should be, neither prescriber nor dispenser in this instance would be allowed to practise in his respective department of physic until compelled to obtain a little information as to his duties. It is monstrous that the public should be permitted to run the risk which is involved here. This is no private question, but one of wide importance. It is not limited to a single case of poisoning, but affects the entire subject of public safety. If the whole truth could be got at it would probably be found that lives are constantly being sacrificed through the blundering of sham practitioners. But it is a point upon which the means of arriving at sufficient information do not exist. The fact, however, is one to which most medical men in large practice can testify, and they will continue to be able to testify to it so long as unregistered persons are allowed to roam about society and physic people at will. It is time that the public took this matter up for themselves. When our lives are at stake, and while it is impossible to detect unregistered persons from those who are registered, it is hard to ask people to be careful in choosing a medical adviser.

## SANITARY REFORM.

### DEPUTATION TO THE DUKE OF BUCKINGHAM.

A DEPUTATION, emanating from the Metropolitan Sanitary Association, waited upon the Duke of Buckingham (President of the Privy Council) yesterday, at the Office of the Privy Council, for the purpose of urging the Government not to abandon a measure introduced under the late Government to give increased powers to the authorities for putting down fever dens, and preventing the overcrowding of houses. This formed the principal subject, but the bill entitled, "The Artisans' Dwellings Improvement Bill," which provides for the rebuilding of houses pulled down under the other Bill, was brought under notice. The deputation, which was introduced by Mr. Powell, M.P. for Cambridge, consisted of the follow-

ing gentlemen:—Mr. Locke, M.P. for Southwark; Mr. Torrens, M.P. for Finsbury; Mr. Graves, M.P. for Liverpool; Mr. Godwin, F.R.S.; Mr. Shaw, Mr. Hall, Mr. Randle, Mr. Evans, Mr. Pocock, Dr. Sanderson, Dr. Hardwicke, and Dr. Bentley.

The deputation having stated its objects at considerable length,

The DUKE OF BUCKINGHAM said—Gentlemen, I am very much obliged to you for the great amount of information you have given me on this subject, and I am glad to see so large a deputation. With regard to the Public Health Bill, I may say that every endeavour will be made to pass it through Parliament. It will be taken up by the Secretary of State for the Home Department, and I shall be very sorry if anything happens to prevent it passing. There are, no doubt, some provisions which it would be well to add to it, some of which have been alluded to to-day, but I would not supplement it in a manner which might endanger the bill. There is as much in the bills in existence, but the more summary jurisdiction of this bill will be valuable. I should not like a single day's delay in this bill. The other bill is of very great importance, and a decidedly necessary supplement to the Public Health Bill. The first bill merely goes to the extent of getting rid of the objectionable houses, and provision must be made for supplying their place. We cannot, keep driving our labourers further and further away. The great evil now is that the men are too far away from their work. We know and feel that in the country. I shall be very happy to see the Artisans' Dwellings Bill passed, as a very important supplement to the other, and it has been brought under our notice, but I cannot say more than that it is our wish for it to pass. I do not think it can be in better hands than it has been in, for there is no more difficult task than to pass a bill through a select committee. If it is brought in by those who have already had it in hand it will meet with every support.

The deputation, after thanking his Grace for the attention he had given, then retired.

## Our Weekly Retrospect of the Medical Journals.

JULY 14TH.

THE *Medical Times and Gazette* reviews the working of the College of Physicians, chiefly in reference to the recent election for Fellows. The existing law in this respect has not given general satisfaction. It is proposed to limit the degree of Fellow to Members who shall have served seven years as such; at present four years is all that is required. No matter what laws the Council may make, it will be found that many will be advanced who have but a flimsy claim for the dignity, and many estimable names will, on the other hand, be passed over.

The dinner of the Fellows of the College of Surgeons, England, seems to have been a very happy affair; it was a convenient wind-up to the election which was so warmly contested.

Several sporadic cases of cholera continue to be reported. It has again made its appearance in Liverpool, as predicted at the termination of the late outbreak some six weeks ago.

A correspondent, "R.D.," in whose pen we recognize the familiar style of an eminent officer of health, writes an exhaustive account of the outbreak of cholera at Amiens, only half a day's journey from London. Every cause which is generally considered as an essential factor in the localisation of the epidemic seems to exist in this unfortunate city; low, damp, permeated by stinking streams, drainless, pauper, some of the drinking water very good, some contaminated by sewerage, with the usual filthy condition of an important department, which is observable in all French towns. The disease, although dying out, does not seem to have been rendered subservient to treatment, but dies out of itself, proving the correctness of Dr. Farre's views as to the culmination and duration of epidemics. The

population are bearing their visitation well in a moral sense, but thousands of the inhabitants have fled. A stranger who visits the scene is looked on as a curiosity, and excites some scepticism as to his state of mind. Of course, it is to be expected that the mortality has been greatest among the lower orders, although some eminent citizens have gone to their account. The various and opposite plans of treatment which have been put in practice are of little use to us. Some propose hippo, others use astringents, many put their faith wholly or in part in opium, but all agree that the cases which have lately occurred do not present that virulence which was observed at the outset; sixty per cent. of those attacked died at the commencement, but sixty per cent. are now saved.

The obituary contains a notice of the death of the celebrated aurist, Dr. Toynbee, who fell a victim to his love of science. He was incautious enough to make experiments on himself, without an assistant being present, on the introduction of the vapour of chloroform to the internal ear by the Eustachian tubes.

A correspondent connected with a French wine grower offers as a present a cask of French wine to each of twelve London hospitals—a very seasonable gift this warm weather.

Dr. Suckling introduces a new practice in the treatment of retained placenta after abortion—viz., plugging.

Dr. L. Earle describes a new method for inducing premature labour, which we do not think will be received with favour.

Mr. Fagrer of the Calcutta Hospital contributes a very interesting case of osteo-mylites which came on after an amputation through the forearm. It recurred in the secondary stump after amputation through the humerus, finally necessitating disarticulation at the shoulder-joint. The case ultimately did well.

The *British Medical Journal* gives a *resumé* of the Appendix to the Third Report of the Cattle Plague Commissioners.

The College of Physicians have taken charge of the valuable drawings of the pathology of rinderpest.

Dr. Cheevers has put in practice Mr. Marshall Hall's suggestion of tracheotomy in hydrophobia. The patients were enabled to drink, and died ultimately, not of spasm of the glottis, but of exhaustion from the spasms as in tetanus.

Dr. Greenhow's Lecture on Addison's Disease contains all that is known on this very dark subject.

Dr. Bracey contributes an interesting case of rupture of a thoracic aneurism into the cavity of the pericardium.

## TREATMENT OF ANTHRAX.

DR. LARGH of Vercelli, describes the form of treatment which during the last twenty years he has pursued with great success in the treatment of anthrax. As soon as he is called to a case—and the sooner the better—he makes a free crucial incision, so as to reach the sound parts at the margin of the tumour, as well as through the depth of its substance, and then proceeds to freely apply the solid nitrate of silver, sticks of which he has ready mounted on an elastic catheter. Every portion of the incised parts, as well as any spontaneous opening that may have taken place, are thus thoroughly cauterized with the nitrate—which, in fact, is thoroughly dissolved, while when the tumour is very deep a second cylinder is applied. A pulsatious semi-liquid mass results, and on this being removed any points whence blood issues are again cauterized. The edges of the wound are also carefully cauterized. The incisions and cauterizations are rapidly performed, and the pain caused is not durable, while a calm sleep soon supervenes. The tumefaction and pain of the anthrax rapidly subside, and the separation of the eschar is allowed to take place spontaneously, a weak solution of nitrate of silver only being thrown into the cavity. Neither erysipelas nor purulent absorption ensues, the fever ceases, and the patient rapidly recovers.—*Annali Univ. di Med. and Brit. and For. Med.-Chir. Review.*

## THE REPORT OF THE MEDICAL OFFICER OF THE PRIVY COUNCIL FOR 1865.

Mr. SIMON'S Eighth Annual Report has just been laid before Parliament. It is full of matter of the highest interest and importance. It deals in succession with the proceedings of the Medical Department of the Privy Council during 1865, in reference to vaccination, the distribution of disease in England and the circumstances by which it is regulated, and finally, to foreign epidemics of the year. The general question of contagion, in its bearings upon the public health, is also considered by Mr. Simon.

1. In respect of vaccination, it is gratifying to learn that the district inspections which have been carried out during several years past, under the direction of the Privy Council, have been productive of good results. In many districts they have led to an improvement in the performance of public vaccination. Mr. Simon justly remarks that "in the present unsatisfactory state of the law even a very little progress deserves mention," certifying as he thinks it does "that, except for that state of the law, the progress would have been far beyond its present stage."

2. The proceedings in reference to the distribution of disease in England, and the circumstances by which it is regulated, relate to house accommodation of the poor, the effects of sanitary improvements, the question of injury from infected rags, certain scientific researches, and occasional investigations respecting local outbreaks of disease. An extensive inquiry as to the housing of the poorer population in towns (harmonizing with one which had been made in 1864 into the housing of the rural poor) was carried out by Dr. Hunter. His valuable report is published in the appendix to Mr. Simon's Report, and will subsequently receive special consideration.

"Large as the inquiry was," says Mr. Simon, "and copious as are the resulting details of information, the broad results may be told in these very few words: that neither against degrees of crowding, which conduce immensely to the multiplication of disease as well as to obvious moral evils, nor against the use of dwellings which are permanently unfit for human habitation, can local authorities in towns, except to a certain extent in some privileged places, exercise any effectual control. Resulting from (or at least attributable to) the powerlessness of the authorities, which only sometimes were supplemented by strained constructions of the law, the evils in question were found very extensively, one or both of them, in operation."

To remedy this state of things, Mr. Simon holds that, in the interest of our labouring population, the local authorities should be able and willing to exercise the following powers:—

"1. To deal universally with overcrowding on the basis of its being technically a 'nuisance,' and to take as the sole test of overcrowding the proportion borne by the number of occupants to size and ventilation of given space.

"2. To apply to the so called 'tenement houses' of the poor a system of registration and regulation akin to that which is applied to common lodging-houses under the statutes of 1851 and 1853.

"3. To enforce everywhere against the use of cellar dwellings the restrictions which, under the 67th section of the Public Health Act, 1848, are enforceable in places which are under that Act and the Local Government Act.

"4. To exercise against premises of parts or premises which, by want of access of light or air, or by dampness, or through ruinous condition are rendered unfit for human habitation, the same powers as against premises which by 'nuisances' are rendered unfit.

"5. To acquire premises, by compulsory sale, either in order to make useful openings and clearings where ground is too closely built upon, or for other sanitary improvements."

These propositions refer to existing and old-standing evils, and they would fairly meet the difficulties which are encountered in endeavouring to overcome them. But there is a question which cannot be dissociated from the state of things to which these propositions have special reference, and which it would be well to consider in conjunction with this state.

It is tolerably certain that in towns and rural districts the progress of building proceeds at a more rapid rate than the progress of sanitary legislation or improvement. A recent examination of the newer houses and cottages springing up, mushroom-like, in thriving centres—even centres where Building Acts exist, renders it well-nigh certain that in a large proportion of instances their construction and arrangement are such as of necessity to entail the most lamentable consequences to the health of the inhabitants in the course of a very brief period. This question, doubtless, does not come strictly within the province of the medical department of the Privy Council, but it seriously demands the attention of the Legislature. And it is obvious that any legislation must be so far defective, which, while providing for the rectification of certain evils, does not provide against the continuous growth of those evils.

An inquiry conducted by Dr. Buchanan into the effect of sanitary works or regulations in improving health in divers localities was completed at too late a period to have a place in Mr. Simon's present Report.

In order to obtain more exact knowledge of the alleged occasional conveyance of morbid contagion in the various stuffs which form the staple of the rag trade, Dr. Bristowe was instructed to make a detailed inquiry. "It is a matter of congratulation," Mr. Simon observes of this investigation, "that the results are almost negative, and such, I think, as fully to establish that the rag trade does not play any considerable part in the distribution of contagions of disease."

It is of great interest to learn that a series of scientific researches in aid of the more immediately practical objects of the medical department have been begun under the superintendence of Mr. Simon. The inquiries already made with regard to the distribution and causes of all our most destructive diseases, and of which the results have been published at length in Mr. Simon's series of invaluable reports, constitute a mass of information unrivalled for precision, extent, and national value. The time has now come when more recondite questions of the genesis of disease may occupy with advantage to the nation the attention of the department, and accordingly series of investigations are now being carried out by Dr. Thudichum with reference to the chemical processes of disease. Inquiries tending to a repetition of evidence on the subjects which had already been dealt with by the department would be of but secondary interest; whereas scientific researches leading to a more intimate knowledge of the nature of morbid processes which are yet to be prevented, and such as were not likely to be undertaken here by private investigation, open out a field of utility of the highest promise.

The third portion of Mr. Simon's Report is devoted to the foreign epidemics of the year, and the general question of contagion in its bearings on the public health. The outbreak of epidemic cerebro-spinal meningitis in Northern Europe, the present extension of epidemic cholera on the continent, and the importation of yellow fever into Swansea last year, give an interest altogether exceptional to this part of Mr. Simon's Report, and to the appended elaborate reports of Dr. J. Burdon Sanderson, on the Epidemics of Cerebro-Spinal Meningitis on the Lower Vistula in Europe; of Mr. John Netten Radcliffe, on the Sources and Diffusion of the present Epidemic of Cholera; of Professor Parkes on the Outbreak of Cholera at Southampton in 1865; and of Dr. Buchanan, on the Outbreak of Yellow Fever at Swansae. We must postpone the consideration of this part of the Report.—*Lancet*.

## DEATH OF A PHYSICIAN FROM AN EXPERIMENT.

ON Tuesday an inquest was held relative to the death of Dr. Toynbee, aged 50, of No. 18, Savile-row, Burlington-gardens, London.

George Power, who had been in the service of the deceased for six years, said that he was last in conversation with his master at ten minutes to four on Saturday afternoon, owing to a patient wishing to see him. He was lying on the couch. He had delayed his luncheon that day until half-past one, and as he usually took a sleep afterwards he told witness not to disturb him for an hour or so. When witness knocked at the door he was answered, "Come in," and on entering his master had apparently awakened from a sleep. There were papers on the chairs and deceased's watch on the table. Before the patient was admitted deceased removed the papers and seated himself in his consulting chair. The interview did not occupy more than a couple of minutes, and on the exit of the patient he said he was coming again on Monday. Another patient called, and on witness re-entering the room he found his master again lying on the couch with a piece of cotton wool over his nose and mouth. The chairs and papers were placed as before. He thought deceased was asleep as he did not answer, and he thereupon removed the cotton wool; but from the appearance presented he became frightened and thought something was wrong. He then ran for medical assistance.

By the Coroner—Witness was not aware that the deceased made experiments on himself. He seemed as cheerful as usual on that day, and paid up his book, as he always did on the Saturday.

Dr. Orlando Markham, of 3, Harley-street, Cavendish-square, found the deceased on the sofa perfectly dead. There was some cotton wool on the table close by, and witness's attention was attracted by a smell of chloroform in the room. The cotton wool smelt strongly of chloroform. Dr. Leared happened to come in at that time, and they both tried artificial respiration for half an hour without the least hope of restoring life. There was not the slightest sign.

By the Coroner—There were papers on two chairs, and a watch upon one set of the papers. On the first set there was a slip which referred to an experiment apparently tried on Thursday last—viz., "The effect of inhalation of the vapour of chloroform for singing in the ears, so as to be forced to the tympanum, either by being taken in by the breath through a towel or a sponge, producing a beneficial sensation of warmth." The second paper was an experiment on "The effect of chloroform combined with hydrocyanic acid." This was not clipped, apparently waiting for a result. Close to his hand on the chair were two bottles, which had been obtained at Bell's that afternoon. The one contained rectified ether, which had not been opened. The second was a little more than half full of hydrocyanic acid. He did not detect any smell of hydrocyanic acid, for that acid would evaporate very quickly. There was also a machine made of indiarubber lying on the chair used for injecting ether or other vapours, and afterwards was found, underneath the sofa, just as his hand—that of a dead man's—would fall, a six-ounce bottle, completely empty, which had contained chloroform but was dry and free from smell. The stopper was not in. From his experience, he should say the appearances were quite consistent with death from the effects of chloroform, but it was not possible to say that there was a combination of hydrocyanic acid with the chloroform, owing to the advanced state of decomposition of the body, both being so volatile that they speedily evaporated in an ordinary temperature.

In answer to further inquiries, he said he had made a post-mortem examination, but not an analysis, as he did not consider it necessary. In fact, there were no contents in the stomach to analyse, and not the remotest smell of the acid, which must have been present had it been taken

in quantity into the system. He believed that the death was due to chloroform, but what effect the prussic acid would produce in combination with the chloroform in vapour he could not tell.

Witness here produced a letter written by deceased to Dr. Gibson on the 6th inst., in which was expressed an opinion that Clover's apparatus for inhaling the vapour of hydrocyanic acid could be safely applied to the tympanum. This was explained by stating that the vapour was inhaled to the back of the throat, and, by holding the mouth and nostrils, was forced into the cavities of the ears, thus removing the singing and other nervous sensibility.

The Coroner—In fact, he must have forgotten his lungs, being so wrapped up in what he was doing to the ear.

Witness—Yes; he forgot that the vapour was getting into his chest.

John Barnard, 338, Oxford-street, managing superintendent to John Bell and Co., chemists, said he knew deceased personally. In consequence of a letter Mr. Hills received from deceased he went to see Mr. Clover's instrument for inhaling the vapour of ether and chloroform. The letter directed that the firm should send to deceased 6 ounces of chloroform, also of ether, and 1 ounce of hydrocyanic acid. He then went to deceased on Saturday morning, at eleven o'clock, to describe Clover's instrument. He said it would not suit him, for it was too complicated. He told him he had directed the things ordered to be sent him. Deceased said he wished to try the effect of mixed vapours for curing nervous affections of the ears, and that the instrument described would not suit him. Witness offered to get him any other that he might wish, when deceased thanked him, and witness left. About a quarter to two he called in Oxford-street, and said witness had not sent the articles ordered, but while there the messenger returned, saying he had just left them. Deceased asked the strength of the hydrocyanic acid which had been sent, when witness replied, "The dilute form." Deceased said, "That will not suit me; it is not strong enough. Give me immediately some of Scheele's strength." He seemed rather annoyed at not receiving the articles, and he appeared in a hurry. Witness took down the bottle, and caused to be supplied some acid of Scheele's strength. He heard nothing more until Dr. Markham came and told him of the lamentable death.

By the Coroner—Deceased was not in the habit of having hydrocyanic acid, but frequently was supplied with chloroform. The "dilute acid" was half Scheele's strength, and quite sufficient to destroy life.

Mr. Valpy, Captain Toynbee, Mr. Gowan, and other gentlemen, testified to the high intellectual and moral character of the deceased, and that being in a prosperous condition, surrounded by a loving family, he had given himself up to scientific pursuits, experimenting upon himself, and leaving nothing undone for the promotion and welfare of his fellow-creatures and the advancement of social science.

The Jury having consulted a few minutes returned the following verdict:—"That the deceased met with his death accidentally, while prosecuting his experiments, by inhaling a combination of chloroform and prussic acid; and the jury desire to express their deep sympathy with the family of the unfortunate deceased gentleman."

The Coroner expressed his concurrence with the verdict and expression of the jury, and the proceedings closed.

At an inquest recently held before Mr. Payne, at the Crown Tavern, Essex-street, Strand, it was stated that the dead-house of St. Clement's Danes is so small and dark that when a medical man is called upon to make a post-mortem examination he is obliged to have the coffin removed into the churchyard, and to have the dead-house doors open to get light, so that the bystanders who collect can inspect the whole operation. The coroner wished the public press to call attention to the state of the dead-house and to the necessity for the erection of a place for the depositing and examination of bodies, similar to the Morgue, at Paris.

**LEGAL INTELLIGENCE.****CENTRAL CRIMINAL COURT.—JULY 12TH.****FRAUDULENT REGISTRATION.***(Before the RECORDER.)*

CROWTHER SMITH, alias JOHN POTTER SERJEANT, 52, described as a surgeon, and JOHN SUTTON, 31, dentist, were charged with misdemeanor in having unlawfully, and by false and fraudulent declarations, procured the registration of the defendant Smith as a duly qualified medical practitioner, under "The Medical Act of 1858." The prisoners were also charged with conspiring together to commit the same offence.

Mr. Serjeant Ballantine, in opening the case for the prosecution, described it as one of a very remarkable, if not even romantic character, and one which also involved many important considerations in reference to the protection of the public from being imposed upon, and suffering severely both in their pockets and their persons, by the proceedings of utterly unqualified medical practitioners. The transaction appeared to have originally commenced so far back as the year 1836; and in that year it appeared that a gentleman named John Potter Serjeant was residing at Leicester, studying for the medical profession, and was no doubt regularly qualified by his education for that position. It appeared that he came to London, and after undergoing the usual examination he received a diploma from the Royal College of Surgeons of England, and subsequently a licence from the Apothecaries' Company to act as an apothecary, and he was for some time, no doubt, in regular practice in London. He was not aware what the habits of life of this person were, but it appeared that he had contracted an intimacy with a lady at Leicester, and that this intimacy continued in London, but about the year 1846 the person, whom he should show was the real John Potter Serjeant died, and from the fact of the cause of his death being delirium tremens, he was afraid that it must be inferred that his course of life was not of the most regular character. All the property he possessed was left to the lady to whom he referred, and amongst it were the diploma and the licence, which were kept in tin boxes, and which were considered by the deceased, no doubt, to be of considerable value. The lady in question subsequently got married, and was now a widow, and it appeared that for a considerable time she took no particular notice of the articles she had received from her deceased friend, and it turned out, several years afterwards, that, in some extraordinary manner, both the diploma and the licence had disappeared, and no one was able to tell at that time what had become of the documents. The case on the part of the prosecution was, that the prisoners had in some mysterious manner got possession of both the diploma and the licence, and that the prisoner Smith, who was an utterly illiterate man, and perfectly unqualified to act as a medical practitioner, had assumed the name of John Potter Serjeant, and that both the prisoners had at different times acted as medical practitioners under the diploma and the certificate which they had undoubtedly fraudulently obtained in the first instance. The learned Serjeant then proceeded to state that in the year 1859 the prisoner Sutton applied to the Medical Council, in accordance with the Act of Parliament, for a certificate of registration, upon the production of the diploma and the licence, and the certificate was granted, and from this time he practised as a regularly qualified man at different places in the metropolis, the name of Dr. Serjeant being upon the door, and one or other of the prisoners constantly practising in that name. These were the principal points in the evidence relied upon to support the prosecution, the substantive charge against the prisoners being that they had for a great number of years practised under the name of John Potter Serjeant, it being clearly proved that this person was dead, and that they had no right whatever to the certificates of competency that he had received.

Dr. Francis Hawkins, and Messrs. Roope and Bell

gave evidence on the part of the Medical Council, and Messrs. Trimmer and Stone on the part of the College of Surgeons of England.

At the conclusion of the case for the prosecution, the learned counsel for the prisoners addressed the jury at considerable length, and with a good deal of ingenuity in behalf of their respective clients.

The Recorder summed up with his usual clearness, and the jury, after a very short deliberation, found them both Guilty.

Mr. Oppenheim informed the court that both prisoners had been previously convicted, or rather pleaded guilty, in this court to a charge of fraud, the offence being that of forging the trade mark of Messrs. Broadwood, the eminent pianoforte manufacturers. Upon that occasion they were sentenced to three months' imprisonment.

John Mark Bull, a detective officer, of the city of London, then stated that he had known both prisoners a great number of years, and they were notorious swindlers.

The Recorder, in passing sentence, said that the prisoners had been convicted of what he could not help considering, under the circumstances, to be a very serious offence. He, therefore, felt it to be his duty to inflict the full punishment fixed by the law, which was, that they be imprisoned and kept to hard labour for twelve months.

The conviction of two men named Smith and Sutton for conspiring to procure the registration of one of them as a qualified surgeon under the Medical Act only shows how extremely clumsy some rogues are, and what unnecessary pains they take to put their necks in the noose which dangles before them, although there be plenty of space to pass on either side. They mistook a scarecrow for a policeman, and turned into the path beset with man-traps, instead of walking boldly on, and defying this mock penal enactment. There are hundreds of quacks of the same order as these, who practise with great success particular branches of medicine and surgery, and with very flourishing titles. Only last week a witness in court incidentally acknowledged that he was practising medicine and surgery, and that he had no diploma whatever, or any medical education. The quacks generally manage to avoid running their heads against the medical act, which is intended to protect the people from their false assumptions of titles, because the penalty is imposed, under its fortieth clause, not for the false pretence of possessing a diploma and being duly educated, but for the endeavour to get registered by fraud, or for untruly declaring oneself to be registered. Now, as not one person in ten thousand in England knows anything about the Medical Register, and not one in a hundred thousand has ever seen it, or ever thinks of asking whether the red lamp in the next street is a trustworthy and registered luminary, the quacks simply ignore the act, and practise without legal title. Smith and Sutton took a world of pains to commit an altogether unnecessary offence, and are lodged in prison accordingly. The act is a complete failure as it stands; it affords no protection whatever either to the public or the profession. And we may take this opportunity of calling the attention of the new Home Secretary to the fact that he will find in a pigeonhole of his office a short and simple bill devised by the solicitor to the Medical Council, and approved by Sir George Grey and Mr. Thring, of which the effect would be to make the assumption of the title penal, as well as its registration. This short and easy protective measure we commend to his early consideration.

CHOLERA AT PERTH.—On Monday afternoon, a man confined in one of the lunatic wards of the general prison at Perth, was suddenly taken ill, and died, with all the symptoms of Asiatic cholera. So far as we have been able to ascertain no other cases have occurred. And at Leith, where two cases were reported last week, no further manifestations of the disease have been noticed.

## Reviews.

**THE CLIMATE OF SAN REMO**, and other Winter Stations of the Mediterranean, including Nice, Mentone, Cannes, and Hyères. By M. PROSSER JAMES, M.D., Senior Physician to the City Dispensary, late Senior Physician to the Metropolitan Dispensary, Author of "Sore Throat and the Laryngoscope," &c.

**SAN REMO AS A WINTER RESIDENCE.** By AN INVALID.

**THE CLIMATE OF SAN REMO AS ADAPTED TO INVALIDS.** By Dr. HENRY DAUBENY.

The first book on this list is medical and scientific. The author has for several winters visited the climatic resorts of the Mediterranean, and has given us in this pamphlet the results of his professional observations. He has been led to adopt the views which he here records from a careful and continued examination of the position of San Remo, and the peculiar advantages which it offers to the invalid as a winter residence, compared with those of the other places of fashionable resort along the coast of the Mediterranean, between Genoa and Marseilles. He appears to have been particularly struck with this Italian town during his first short visit, and resolved to spend the following winter there to ascertain if his original impressions were well founded or not. A further investigation confirmed him in the opinion he had formed, and led to the publication of the work which we here introduce to our readers. It is well written, the style is vigorous, often bright and sparkling, the meteorological statistics are carefully collected, and the conclusions at which he arrives always fairly deduced from the reasons assigned.

Indeed, if to be plagiarized be a proof of value, Dr. P. James may well be proud of the manner in which his work has been made use of without acknowledgment. Both professional and literary critics have already pointed this out, and therefore we refrain from a full investigation. We may, however, cite the tables given by Dr. James from unpublished records, as well as others from newspapers, both translated by him for this pamphlet, and which have been transferred bodily to the pages of Dr. Daubeny as if they were literally his own. It is rather amusing to observe that by a clerical error Dr. James cites Sir C. Clarke, which error Dr. Daubeny most innocently copies.

Mr. Aspinall's book, the second publication which we here notice, is popular and gossiping. It is a pleasant narrative of the feelings of "An Invalid," when he reached, as he himself says, "bright, beautiful, exhilarating Liguria," and when, after the "first few weeks spent at San Remo, he began to experience the exquisite sensation of returning health, and was enabled to enjoy long rides amongst the charming scenes with which this lovely country abounds." The volume is quite unpretending. It gives a description of the new and the old town, and a condensed *epitome* of its history. It points out the objects of interest to be found there, enumerates the natural productions of the climate, gives full directions for finding the road leading to the different localities in the neighbourhood where there is anything remarkable to be seen, or where the most striking views of this mountainous region are to be obtained, advises the best method of proceeding there, whether by a donkey-ride or on foot, and indicates the places for rendezvous or pic-nic. Indeed, it furnishes almost all the information needed by a visitor, and that is usually comprised in a far less interesting form in an ordinary guide.

We have only to remember one fault in Mr. Aspinall's volume, that he has cited, instead of Dr. James, his plagiarist; but we must, at the same time, bear in mind that Mr. A.

as an invalid resorting to San Remo might know nothing of the respective dates of their publications.

Dr. James's work was the first in point of time, and is unquestionably the most important. There are some lively descriptions of places and scenes which will interest the general reader, while to the profession it will furnish many valuable hints which may guide them safely in recommending a winter residence to their invalid patients.

As to Dr. Daubeny, we advise him openly to acknowledge the source whence the chief part of the information contained in his pamphlet was derived. Should he, however, decline to do so, he ought unquestionably, in fairness, to suppress the remaining copies.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 18, 1866.

### MEDICINE AND THE NEW MINISTRY.

The profession of Medicine has so little reason for the expression of gratitude to any of the Administrations which have successively held the reins of government that the late changes in the Administration will probably be regarded with a feeling of indifference, relieved perhaps with a gleam of hope that, as things cannot well be worse than they are at present, they may possibly be better. In a Medical Journal politics are of course beyond the legitimate sphere of discussion, but it must be admitted that the late Ministry exhibited in general the utmost disregard for the interests or the advancement of the Medical Profession, and the rare cases in which honours were bestowed upon its members were rather to be regarded as exceptions than as a rule. In all the instances where medical matters were discussed in the Legislature scarcely common intelligence was displayed in the debates, and a sentiment of apathy, if not of positive opposition, was manifested whenever the interests of our Profession were advocated.

No better proof could have been given of the utter listlessness, if not contempt, felt by the late Government towards Medical interests than the conduct pursued in reference to the amendment of the Medical Act. This measure, as is too well known, has entirely failed, not merely to protect the Profession, but to protect the public, or even to effect the small object at which it professed to aim—namely, the indication of the difference between licensed and unlicensed practitioners. But notwithstanding the repeated representations and remonstrances made to the Government, nothing whatever has been done or even proposed in Parliament to rectify the obvious anomalies and imperfections of the Medical Act, and all that the late Home Secretary has done has been to grant the services of the Solicitor of the Home Office in drawing up some heads of an amended Bill, which, however, has never received any official sanction, and has now been abandoned altogether.

The grievances of the Poor-law Medical Officers have elicited no response from the late Government, and the stolid red-tapeism of the Poor-law Board has steadily resisted all the efforts of the Poor-law Surgeons to ameliorate their own condition. These gentlemen are perhaps, at present, not quite so much crushed as they previously were by the tyranny of the local Guardians; but the improvement, if improvement it can be called, is owing, not to any exercise of legislative or official power, but to the exposure, in the newspapers and by a voluntary association, of gross defects in the management of the sick department of the Workhouses, defects which are obviously due to the ignorance of local Boards upon sanitary and Medical subjects, and to their contemptuous and offensive behaviour to their Medical Officers.

It remains to be seen whether the Earl of DERBY and his colleagues in the new Ministry will bestow a greater attention on Medical matters than his predecessors have done, and we may state, in the first place, that the present Government are, in some special way, bound to remedy the defects in the Medical Act, which was a bantling of their own production. Most of us can recollect the rapidity with which this Act was passed, under the last Conservative Ministry, of which Lord DERBY was the head, and it is quite possible that if its amendment were promoted under the same auspices, the results might be satisfactory to the Profession. At all events, the practitioners of Medicine have a right to ask the present Ministry, with far more urgency than of the last, such alterations in the measure as may render its provisions at least intelligible, and enable the public to comprehend the reasons why it was ever passed. At present there has been but little gained by the Medical Act of 1858, except the representation of conflicting corporate interests at a central Board, the annual discussion of plans which come to nothing, the publication of a Register which few in the Profession and none out of it ever care to read or consult, and the levying of a large sum of money from an ill-paid and over-taxed Profession.

The only topic in relation to the Medical Profession which has hitherto been touched upon by the Earl of DERBY is the improvement of the condition of the sick poor in the Workhouses, but this subject at present occupies so much of the public attention that legislation will not be very difficult. The interests of the poor in this case are almost identical with those of the Poor-law Medical Officers, who are the real friends of the sick poor, and stand between them and the Guardians, and any measures calculated to improve the state of the Workhouse Infirmaries must necessarily tend to improve the status of the Medical Officers. If Lord DERBY should succeed in remedying the abuses which are proved to prevail in the management of the sick poor he will be regarded as the benefactor of the community, and we may add, he will show himself more worthy of support than those whose philanthropy thereby engages

them chiefly in foreign sympathy, but blinds their vision to the abuses prevalent at home.

### MEDICAL FEES IN TOWN AND COUNTRY.

IN our last number we directed attention to the formation of a Medical Protection Association for the Lothians of Scotland, having for its object the due reimbursement of country medical men for their skill and labour. With much sympathy for our country medical brethren, we must confess to an equal sympathy with our agricultural labourers, who are a hard-worked, ill-paid set of men, and yet the backbone of our country, and having a strong desire to mediate between the two, we beg to suggest some such plan as the following, which we think would be found to work well for all parties. We think that all farmers and other large employers of labour in the country should act as the managers of collieries and ironworks are in the habit of doing, they should deduct a certain weekly amount off each man's wages for medical attendance and medicine, leaving midwifery to be settled for separately and per case, and rating the amount at so much less for bachelors than for married men. This mode would at once secure the doctor his fees, and at the same time not oppress the labourer, while it would also suit the employer, as the patients would be sure to apply early, and would, therefore, have the best chance of being cured early. Let the Lothians Medical Association press this view of the case on all the employers within their bounds, and we are sure it will receive all due consideration, and will probably settle their difficulties at once. In towns, however, the case is somewhat different. In them we have a large class just barely above pauperism, and only kept from sinking into it by medical and other charities; from them nothing can be expected, but on their behalf the State ought to subscribe largely to these charities, because it is by them relieved of a large part of its proper burdens. A proper system of medical organization would compel this, and it is only not needful, because those charitably disposed relieve their brethren to the extent necessary, and we believe that, morally, this is far better than for centralization and organization to apportion each man his proper share and tax him to that amount. In towns, also, there is, from the great facilities, a large proportion of black sheep, who, after exhausting the patience of one doctor, flit to another, and, mayhap, confer their patronage on a third, having, all the while, the dispensaries to fall back upon in case of refusal to attend; for this there is hardly any remedy without importing into the profession more of the commercial spirit than we have any desire ever to see within it. These are two burdens which weigh more or less heavily on every practitioner in a town, which are, to a large extent, irremediable, and which serve, at considerable personal expense, to keep alive his charitable feelings. In Edinburgh we have also another source of trouble, and in many cases of loss. We have no such thing as a fixed table of fees. Advocates have their retaining and refreshing

fees, the amount of which they fix for themselves. Writers have a regular and fixed scale of charges; but medical men take off their hats and beg. We have given you our advice on so many occasions, we have paid you so many professional visits, what do you think them worth? What will you give us for them? Such a mode of acting is embarrassing to both patient and doctor till they get accustomed to it, and we certainly think it far less gentlemanly than a plain statement of what we think to be the value of our services. If we practise as advocates, as writers, or as doctors, the fact itself shows that we require to supplement our patrimony, or supply our wants by selling our services to those who need them. Why should one only of these professions, and that not socially the highest, decline to state what it deems these services worth? This anomalous state of matters requires to be set right and placed upon a firm basis, and the profession would not lower itself, but the reverse, in the eyes of every right-thinking man by so doing. It is all nonsense to say that we have no means of knowing a man's income, that we must not oppress the poor nor sponge upon the rich; in the sum paid for house-rent we have an approximative index to a man's means, and certainly a fair basis in accordance with which to draw up a table of fees, and we feel certain that both the profession and the public would be thankful to have some authoritative and definite regulations to guide them in their pecuniary relations, which would yet neither prevent a man asking more if he felt himself in a position to do so, nor oblige him to refuse any additional *douceur* to which a grateful patient might think his services entitled.

#### THE TEACHING OF PATHOLOGY.

We are sure that no one will dispute our opinion that pathology in its enlarged sense as the science of disease, the history of morbid processes, and their mode of differentiation from healthy ones, constitutes the only firm basis whereon to found a rational system of medical treatment. Pathology, as thus understood, is neither a doctrine of crases, of cells, nor of exudations, but a true science, necessitating a knowledge of all these matters and of something more. Every deviation from the normal in structure or function is a pathological product, and the unravelling of the causes, as well as of the tendencies of such deviations, is the true work of pathological science. But to unravel these causes and tendencies, the mind of the inquirer must be thoroughly conversant with healthy physiological structure and function, and with their laws which regulate the latter, as well as wholly untrammelled by any prevalent theories as to the actions of remedial agents. After the pathologist has determined his premises and laid down his laws, it is then time for the practitioner to inquire how far the agents he employs have the power of modifying them, or how far his preconceived theories of the actions of remedies must be modified by the facts ascertained by the pathologist. In this view of the matter it cannot

but be subject of regret how little has been done in Britain in regard to placing pathology on a proper basis. In this country practice is the El Dorado of physicians, and pathology itself, which ought to be a lifelong study, is, like everything else, only employed as a means of making one's name known, as a stepping-stone into the more fruitful fields, in a pecuniary point of view, which lie beyond. This, however, is not as it ought to be; every large hospital ought to have attached to it a Chair of Pathology, so well endowed as to give no inducement for its occupant to stray into more golden but less scientific fields. In Edinburgh we are peculiarly ill-situated in this respect; we have a Chair of Pathology, unconnected with the hospital, the teaching from which is purely theoretical, while its occupant devotes his life, not to study, but to practise physic; while connected with the hospital we have a practical pathologist whose position is unendowed, and whose sole hope of gaining a competence is to make use of that position as a stepping-stone to practice. Between these two stools pathology falls to the ground. Mere theoretical pathology may suffice to teach a smattering of doctrines already effete, but can never conduce to the useful development of the science, while no sooner has our practical pathologist gained sufficient experience to begin to make his knowledge available in the development of the science than he finds that he can also make it useful in gathering riches for himself, and so he merges the pathologist in the physician. We very much regret that this should be the case, and, considering the vast importance of the science of Pathology, we are sure that we are not overstating the matter when we say that the School of Medicine which shall first sufficiently endow a Chair of Practical Pathology and receive an efficient man for its occupant is certainly destined far to outstrip its competitors. We should be sorry to see Edinburgh behind in this; it numbers amongst its professors men whose names are second to none in medical science. But suppose we had a VIRCHOW here? Would not the efficiency of the school and its fame be increased tenfold. Yet we have ample material and able men; all we want is an endowment sufficient to induce these men to devote their lives solely to pathology. Cannot that, too, be provided?

#### THE CATTLE PLAGUE IN IRELAND.

THE history of this calamitous disease in Ireland is so remarkable, and so clearly opens the question of whether it is desirable that medical or other professional subjects should be discussed in the ordinary journals, that we propose to review it briefly. Towards the end of May it was reported to the Castle authorities that a disease which had been smouldering for some weeks at Drennan, near Lisburn, was rinderpest, and such it was at once pronounced to be by the Head of the Veterinary Department and an English Cattle Plague Inspector of much experience. Doubt was cast on this opinion, mainly because post-mortem examinations had been considered unnecessary, but all approved of the vigorous

measures which were taken towards stamping out the disease. It had been introduced by drovers and dealers returning from Scotland. Early in June another outbreak was reported at Drumra, just outside the cordon which had been drawn round Drennan. The authorities requested Dr. MAPOTHER to witness post-mortem examinations of the animals affected, and it might be supposed that any deliberate opinion his on this pathological subject would be considered conclusive. He detailed the symptoms which one surviving beast presented and the appearances of its carcase and organs when slaughtered, as well as those of three other cows, which had succumbed to the disease. Every symptom and appearance which is recorded in the Commissioners' Reports and other authorities were noted as being present, and pleuro-pneumonia, milk fever, and foot and mouth disease were put out of the question, not one character of any of them being observable. This decision was verified by some seven or eight Veterinary Surgeons, who had studied cattle plague in England, and who were present at the dissections, and by many others who examined the diseased specimens when sent to Dublin. It was impugned, however, in one of the morning journals, in which pathological matters were talked of so glibly as to warrant the vulgar belief in editorial omniscience. As recently as last Friday week a portion of this report and a description of malignant catarrh were placed in parallel columns in this paper, from which it appears the writer would infer that the animals had died of that disease. The descriptions are, however, remarkable for dissimilarity instead of identity.

The effusions of this journal, and the clamour of a number of persons interested in the cattle trade, induced the Government to bring over one of the Officers of the Cattle Plague Department of the English Privy Council. Mr. GEORGE BROWNE, who is so well known for his manual of "Microscopical Anatomy," in conjunction with Dr. HARLEY, was selected. He had taught the diseases of cattle for many years at Cirencester Agricultural College, until, together with many of the other Professors, he was compelled to secede from that institution for reasons in no way discreditable to him. We mention the latter circumstance as it has been the text for a personal attack in the journal to which we have so often alluded. He had acted as Chief Inspector in London and other parts of England since the outbreak of the disease. Arrived in the infected district, he very deliberately observed the cases, not volunteering his opinions to the reporters of the provincial papers—and hence much wrath; but in due time reported to the LORD LIEUTENANT that they were unmistakable cases of rinderpest.

Together with Professor FERGUSON he has announced the same sad news from Enfield, county Meath—the county above all in which an outbreak would be most destructive.

After the animals had been dissected and buried, an

expedition of the sceptics arrived at Enfield, and from the hearsay of the herds and such persons ventured to assert that the cases were "typhoid pneumonia." We regret to say that Mr. FARRALL, the well-known Veterinarian, lent himself to so unprofessional and injudicious a course.

This resolute determination not to believe that rinderpest has appeared in Ireland in spite of any evidence, has already done much injury by inducing humble farmers to treat their stock without giving notice to the Government officials. But from the report of the Mansion-house meeting for the last two weeks it would appear that a better spirit is awakening. One respected member of the Committee withdrew his name to mark his disapproval of its conduct, several followed his example, and others proposed a vote of confidence in the head of the Veterinary Department.

Two facts alone could at first have given any colour to the disbelief of the appearance of the disease in Ireland. First, in the Enfield case, it could not be ascertained with certainty how the disease was imported, but the same had to be confessed in hundreds of outbreaks elsewhere; and second, it did not spread extensively. This may be attributed to the isolated condition of the small herds attacked, to the summer temperature, which greatly lowers the danger of contagion, and above all to the prompt and vigorous measures which were adopted by the Executive.

In conclusion, we do not apologise for having occupied so much space in discussing this mislady, so interesting in its pathological features, and so fraught with danger to national prosperity, as to have attracted to its study some of the ablest physicians in London, not exclusive of the illustrious Sir THOMAS WATSON.

#### JOSEPH TOYNBEE, F.R.S.

WE cannot but add our tribute to the general feeling of respectful sorrow which has been elicited by the death of Mr. Toynbee. The details of the accident which caused it are no doubt known to our readers from the reports in the public papers, which, we believe, are accurate, except in respect to the "commercial speculations" in which Mr. Toynbee (doubtless to the surprise of his medical brethren) is said to have indulged. This is, of course, an error of the reporters, "commercial speculations" being put for *investments*. Mr. Toynbee carried on no speculations, nor had he incurred any losses in the recent panic. A death encountered in the prosecution of experimental research in the domain of therapeutics forms in some sense a not inapt termination to a life so full of labour often undertaken with little regard to personal reward or safety. Few lives, indeed, even among our own laborious fraternity, exhibit a history of toil so zealous and unintermitting. Not far short of one hundred contributions on the subject of aural surgery alone have marked his life of 50 years. His father was a farmer, known as a successful

breeder of cattle at Heckington, in Lincolnshire; but a love for the practice of medicine seems to have been a family taste, since no fewer than three of the sons adopted it. Of these Mr. Toynbee is the last. He entered the profession as pupil to the late Mr. Wade, at the Soho Branch of the Westminster Dispensary. Here much of his time was spent among the lanes and courts of St. Giles, in alleviating the sufferings of the sick poor; and no one who recalls his cheerful friendliness of manner among the poor, and the unwearied efforts which to the last he continued to make for their welfare, can doubt that his duties were not only faithfully performed, but were graced by a kindly sympathy of manner that must have rendered them doubly valuable. Mr. Toynbee both understood and respected the poor. He would often express his dissatisfaction with visits made to their houses merely on errands of charity, and longed and laboured for a time when common knowledge and mutual interests should open a door to a mutually respectful and natural intercourse between the different classes of society. One of the chief attractions which the scheme of Local Museums possessed for him was the prospect it opened in this direction. Probably these habits of thought first sprang up amid the wretched courts and alleys in which his duties lay at the commencement of his professional career; at any rate, it is to this period we may no doubt assign the origin of that philanthropic zeal, which almost grew into a passion in his bosom, for improving the dwellings of the working classes, and for which his position as Surgeon to the St. George's and St. James's Dispensary soon opened a wider field. Here he set on foot the "Samaritan Fund," by which that institution still adds to the completeness of its beneficence; and directing his own attention specially to the ear soon attracted to his out-patients' room a very large attendance of the deaf. He practised at this time in Argyle-place, but his success, though latterly very great, does not appear to have been rapid, as might indeed have been expected from the strictly scientific character of his work. At one time, we believe, his public labours seemed seriously to threaten his private practice, and this led him to take a less prominent, though scarcely a less active, part in many public movements than would otherwise have naturally fallen to him; but a genuine modesty of character, and a wish rather to do than to appear, contributed to the same result. He gave, anonymously, on one occasion, £500 to the Medical Benevolent Fund, of which he was for many years a most efficient treasurer. It would be easy to multiply details of his benevolence, but we forbear. It is, however, only just that we should briefly refer to certain events connected with his mode of taking fees, which at one time excited unfavourable remark. Without attempting to justify any particular case in which an excess above the usual fee may have been charged, we feel bound to affirm, as a matter beyond all question, that the motive which in this mainly influenced Mr. Toynbee was a regard to what he considered the just

rights of the profession, whose claim to a higher rate of remuneration, in certain cases, he held to be indubitable. Here, as elsewhere, even if mistaken, he took his stand, with a view to rectify that which he thought wrong. Of no man can it be more truly said that he lived a hidden as well as an external life. The general outline of his work is known to all, but the diligent and steadfast perseverance of which it was the fruit, the truthfulness and love of science which prompted and controlled his labours, the kind-heartedness and readiness to teach and to assist, which lay beneath an exterior that sometimes did scarcely justice to the man within, those only know whose privilege it was to hold a place among his friends and to share his private moments. That he almost alone raised aural surgery from chaos to the rank and dignity of a not unworthy branch of medical science, though a legitimate title to honour, is yet among the lesser of two claims to respect and gratitude. Unremittingly he toiled for his fellow-men, following with kind sympathy and kinder deeds every want which solicited his aid, every wretchedness, however sullied, which his hand could reach. Though sensitive to physical distress, his wisely-ambitious charity aimed constantly at a higher end than its mere relief. Above all things, he sought to elevate the minds and hearts of his fellow-men, and till the last moment of his life—spent as it was in self-sacrificing effort to extend his medical power—his mind teemed with fresh schemes for spreading the pure and purity-producing love of Nature among the poorer classes of the community. He had faults and he fell into errors, but those who knew him know that even his faults had had a tinge of virtue in them, and chief among his errors seems to have been an enthusiastic belief in the power of right, which led him sometimes into a too zealous effort to effect that which might perhaps have been more wisely left unattempted. Scarcely less in that in which he failed than in that wherein he succeeded, he has laid under a permanent obligation the student and practitioner of medicine.

J. H.

LAST Thursday a child was admitted to the Liverpool Workhouse suffering from cholera, and died in a few hours. This gave the signal. On Friday night four children and a nurse were seized with "Asiatic cholera" in the Foundling Ward of the Liverpool Workhouse. In three hours one of the children was dead. On Saturday morning the nurse died, and the three remaining children were reported to be dying. It may be proper here to draw attention to the Registrar-General's report for the week preceding this outbreak. Clearly Liverpool was in a most unhealthy state, for the official returns give the mortality at nearly twice that of London, and more than double the mortality of Birmingham. Even Vienna shows a lower rate by 8 in 1000. The newspapers tell us that energetic measures have been taken to meet the circumstances. We sincerely hope the officials are really alive to the danger, and we earnestly entreat them to make some inquiry as to the peculiar unhealthy state of their town.

## Correspondence.

### DISINFÉCTION AND THE CATTLE PLAGUE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have observed that the investigation which has been set on foot as to the state of the metropolitan workhouse infirmaries, has been entrusted to Poor-law Inspector Farnall and a Dr. Smith. Can it be that the last-named gentleman is Dr. Angus Smith, whose proceedings in regard to the inquiry touching cattle plague disinfectants have given rise to so much unfavourable remark? If so, I think a considerable portion of the public will have very little confidence in the conclusions he and Mr. Farnall may arrive at. The medical world in particular can hardly be expected to accept as an authority an individual whose pursuits have not been of a kind to familiarise him with the details of hospital routine.

It would seem to me that in respect to this inquiry Dr. Smith not being a medical man, but a professional chemist, and not a Doctor of Medicine, but a German Doctor of Philosophy, has gone beyond his "last." I should like to see it explained wherefore an investigation which has been obtained on account of the pressing representations of a medical journal, and which is of a nature specially requiring that knowledge of hospital arrangements and management which none but medical men can be expected to possess, should be placed in the hands of a non-medical gentleman in conjunction with a Poor-law Inspector. I suspect it will turn out that one of the principal features of Dr. Smith's part of the work will consist of a fresh series of observations with his "air test." If such should happen to be the case, it is to be hoped that they will prove capable of verification, which is more than can be said of some of the air-test observations he has already published.—Yours obediently,

ONLY A SURGEON AND NO PH.D.

### LETTER OF "CYCLOPS."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Last year, before the amalgamation of THE MEDICAL PRESS with THE MEDICAL CIRCULAR, I sent to the latter journal thirty-three consecutive letters on physiology. I have now a case to record of great magnitude which occurred to myself, in which I followed out the great rules I there laid down, and I now ask you if you will kindly insert it in your journal, as it may be interesting to your readers as illustrative of great principles, and oblige, Sir, your obedient servant,

CYCLOPS.

London, June, 1866.

#### A PHYSICIAN'S FORTNIGHT'S ILLNESS—PREDISPOSITION TO DISEASE—A SEVERE COLD FOLLOWED BY RAPID FEVER AND ERYSIPELAS—DESQUAMATION—DIET AND TREATMENT—RECOVERY—PHYSIOLOGICAL REMARKS.

Respecting the physiological problem that any person may be suddenly attacked by any great disease whilst in perfect health, I have always insisted that such is opposed to all physiological laws. The general condition and state of such individual should always show some previous departure from a true balance of health in the system, although such person might apparently be in his usual good health and able to perform all the duties of the healthy individual in every way; still, when we see, as we do, a certain number of individuals taking an epidemic or an endemic, and others entirely escaping, I hold that all those who take the disease have what is called "a predisposition," which term, vague as it is and so little understood, yet actually amounts to that state I have set forth as a principle—namely, that in some chemicovital conditions at present undeveloped by science, yet, nevertheless, should be brought to bear upon it, shows a want of balance of certain states and secretions of the

body, and that it may at any time be upset and take on disease.

At the latter part of last year (1865) and beginning of this, I observed neuralgia to be more prevalent than I had seen it for some years at one time, and that persons in all classes of society, high and low, rich and poor, had it, while, of course, many were exempt. Here, then, is the fact of a departure from that chemicovital law which makes perfect health, and that any such person might be liable to take other diseases solely from this fact. I had neuralgia myself at this time, which lasted off and on for nearly two months. It was the only thing I had to complain of; but it never interrupted my professional pursuits, nor my eating and drinking or general habit of body, for in every other particular I considered myself in tolerable health. Nevertheless, here was evidently a departure from a true balance of health. Again, about March this year, I had many cases of a singular tracheal congestive cough more prevalent among adults and middle-aged persons. I had it myself for two months, and so like a chronic whooping-cough was it, that I designated my own to be nothing more nor less than this disease. The expectoration was enormous, and the noise in the inspiration while coughing resembled the whoop. Indeed, several medical men who had had cases of this kind under their care called upon me to ask my opinion on it, as they could not find any disease of the lungs themselves. On comparing notes they agreed with me that this singular attack which appeared so general was nothing more nor less than tracheal congestion, and resembled chronic whooping-cough. This congestive action and consequent irritation seemed to extend from the chordæ vocales to two-thirds down the trachea, often not reaching even to the bifurcation. The adults who had it, having power to expectorate freely, did so.

The treatment I adopted and recommended consisted of generous living and diet with expectorants and plenty of fresh air, which seemed to keep it under control, but not to reduce it entirely under two months. This was about the time my own attack lasted, yet in every other respect I had fair health. Some of my own patients had already compared their attacks to the same cause from the similitude of the coughs to some of the younger members of their families who had had whooping-cough.

Now these two prevalent diseases I mention by the way to draw the attention of my medical brethren to them should they have seen them, and yet not noticed their singular epidemic character, as well as to lead me up to the first observation that my system was evidently out of a chemicovital balance of health, and was prepared from such predisposition to the attack of which I am about to speak.

On 5th June last, in the midst of what I may call my usual health, I felt, towards the middle of the day, great lassitude and debility, attended with curious aching pains throughout the whole body, and by the time I usually leave my town residence for the country, I felt unusually ill, so hastened home as quickly as possible. By this time I was thoroughly subdued, and went to bed, suffering with alternate rigors and intense painfully cold sweatings, and then bursting into fiery heats. The peculiar sensations of patients, I think, for the sake of physiology, should be recorded. I seemed to lose all identity of myself, and believed myself a mere nebulous mass, and it appeared to me that a few imps of darkness, regardless of my fourteen stone weight, had quietly tied me up in a common silk pocket-handkerchief, and by the four corners tossed me into a furnace—a veritable pandemonium. My thirst was unquenchable, my body a burning surface. In this furnace I seemed, for some thirty-six hours, to sink and sink lower and lower, yet I felt to want support and plenty of cold drinks; so I had every two or three hours, from a delicious cold cellar, tumbler after tumbler of porter and strong ale alternately, with draughts from an unparalleled well, whose water is both pure and cold. Cold applications to the body evaporated as soon as put on.

The third day my friend, Mr. B., was summoned to my bedside—a man second to none in the perfect knowledge of every branch of his profession. "Well, Dr. C., I am sorry to see you so ill, but I have always a difficulty when I approach your bedside, knowing your peculiar views as to medicine." "Well; then, B., leave it alone," was my reply, "I am taking no end of cold drinks—porter, strong ale, and water; water, strong ale, and porter, alternately, and they seem to do me good." "Well, if they suit you and you

think it right go on; but what is this red patch on your cheek? Why, you have erysipelas setting up!" And true enough it was; and like its name it ran like wild-fire over all the right side, ear, neck, and back of the head. Next day, a corresponding patch came on my left cheek with even greater virulence, and ran as rapidly over the left ear, neck, and back of the head. Here it seized on some old and wonderfully deep cicatrices of my friend, Mr. B.'s, scalpel of eleven years ago, when I had a carbuncle of great magnitude, that sent me *hors de combat* from my profession for three months. I suffered all the pains of the carbuncle over again, barring the deep and ghastly incisions. The erysipelas extended to my back and shoulders, and altogether I suffered the torments of the condemned.

Now, as I lay writhing in bed, I wanted to find a cause for these agonizing pains, I tried to reason upon them physiologically, and at last came to the conclusion they were caused by the sudden drying up of all my secretions, and with them the disturbance of all the chemic-vital actions, as well as the sources from which arise our natural galvanic or electrical powers of life, and also from the constriction of all the circulating vessels, and I don't think my conclusions were wrong, as I will show bye-and-bye. Goulard's lotion combined with camphor julep was freely squeezed from linen rags over my head and face, and the cool trickling through the roots of my hair and down my face and neck were most delicious. Curious enough my tongue was clean, and my pulse not bad, and my appetite such that I could take meat and nonrishing things when fed, but I could not feed myself. On the sixth day my head and face feeling like the side of a house, was so disfigured that I should not have been recognizable by my oldest friend. On the seventh day a new feature set up. I burst into such terrific perspirations that I sopped everything I wore, and immediately a new train of symptoms set in. The horrible racking pains I previously suffered now gave place to a different class. All the lakes and springs, rivers and seas, and ponds of the body, seemed to relax; all the circulating vessels and the pains from their distension, and the fluids once more coursing through them seemed to quiet me, and I could bear them apparently without moving; whilst the others, from an entirely different physiological source, caused me to writhe, and, as I lay, I often tried to calculate how many different positions and angles of the body and limbs a patient might make and get into, and how many times he might roll a good old four-poster, six feet square, in an hour. My calculations got to many hundreds. But with these new symptoms came other curious sensations. I could not now bear anything cold to drink, but wanted everything hot; and the quantity of boiling hot—but not strong sherry and water—I drank I must forbear to mention. It seemed as if I could not get enough of it. I felt a sensation (here the sick man's fancies appear again) that I had in the upper part of my trachea a great black hole, about an inch wide, and three inches long, and when I drank the hot sherry and water, it seemed to fill it up. Now, curious enough, this had been the seat of my tracheal congestion, or chronic whooping-cough for two months. The effect on me was that it warmed and stimulated the anterior and posterior mediastinum, and to have a specific action on all the upper part of the heart.

On the sixth day, my friend, Mr. B., said, "How are your bowels?" "Oh!" I said, "they are good friends, they are conserved, they have not been opened since my attack." "Well, I know you have peculiar views on that subject, but should they not be opened?" "No, not till Nature dictates." Physiologists do not yet know the value of the gases generated from fæces, nor the value of the fæces themselves as fæces. In the evening, however, I had a very black solid motion. "Oh!" said I, "here is plenty of carbon; all the burnt up and charred materials after Nature had extracted from them their precious gases."

Next day I had a similar motion, and the following a natural solid one in colour and consistence, and every day since one of the same character. On the ninth day desquamation of the erysipelas came rapidly on, and I could bear no longer the cold applications, so I applied starch powder to all the parts. My pains gradually subsided, excepting that I lay with difficulty on the back of my head, and the great bunches of red and purple spots on my shoulders and back pained me much. Desquamation of my face, as I have said, was most rapid. I had been fed on beautiful lamb and mutton chops, egg and bread crumbed,

and plenty of hot sherry and water. Now, I could compare the desquamation of my face, ears, &c., to nothing but one of these egg-and-bread crumbed chops when cold. Directly you cut them, the mass of egg and bread crumbs comes off, leaving the chop bare. So the desquamation of my erysipelas. All came off, and left my face as clear and rosy as it had been before, and no one would have believed I had had such an attack.

On the eleventh day I got up for a few hours. On the twelfth day (Sunday) I got up and shaved for the first time. This was a terrible operation, but I found the skin beneath well healed. On the thirteenth day I was up all day, and on Tuesday, the day fortnight of my attack, I came to town to follow my usual consulting practice; but, feeling dreadfully weak and quite the invalid, I could only say with Cæsar, "Give me some drink, Tiberius, like a sick girl."

Now come the important points to be considered. I took no medicine of any kind from the beginning to the end of the disease, excepting a dose of morphia, which could not be repeated, and, as suggested by my friend, Mr. B., a little acid and quinine the last five days, which was very grateful. The art and mystery of medicine can therefore claim no credit in the case. The homœopaths might step in and say you did nothing, but where is the humbug of their globules to credit them with anything? Well, then, there is nothing left but the *vis medicatrix nature* and common sense to fall back upon for explanation, and in the former we must look somewhat to a knowledge of physiology. In the first place there was a rapid wasting and a house in a blaze, water quenched the fire to some extent, but the porter and ale supplied that part of the fabric which was being rapidly consumed, for I have observed this great physiological law—namely, that Nature never has a disease, even from its first onset, but that she immediately, by the *vis a tergo* of her chemic-vital powers, begins to repair from her cases of operations, both actions going on at the same time. That I have for many years been of opinion that we do not understand fevers and great inflammatory actions, inasmuch as we keep them too low, and do not properly assist Nature's great laws of reconstruction. Next, as I have always said in my physiological writings, man is an acid generator, and everything he takes in the shape of raw material or diet, barring the direct acids, are alkaline or highly alkaloid. Stimulants and diet in my case were all the medicines I wanted. The fire burning up all stray material was first subdued by cold, while the structure was not allowed to be over-consumed, because the mere act of absorption of fluids through porous structure increases temperature, and it would not have been at all consistent for a certain temperature to be suddenly reduced; for if that once takes place the power of reconstruction of elements is taken away, so that as fast as structure was burnt up in one sense of the word, a reconstruction of material took place, which was, no doubt, assisted by the porter and ale.

Then, again, the uses of the fæces were most important to supply the vital gases to the body. If salines or aperients had been used these elements would have been swept away, and Nature been left to find others where she could. Here, then, is a great field for the consideration of the physiologist, which I have endeavoured to force on his notice, and he who should stand by the bedside as the *opifergue per orbem dicor*, is, alas, the great destroyer of his species, through obedience to the falsest dogmas that ever gained current belief, and he, unknowingly, and through utter ignorance of the laws of life and physiology, sweeps away the very elements which Nature herself designs to uphold—structure and life. The conservatism of the colon, and making use of the fæces as the agriculturist makes use of his manure, was the great act which led to the upholding of all the natural powers, and assisting them in every possible way to supply the deficiency of what was burnt up and destroyed.

Those who might have read my letters on physiology in last year's CIRCULAR, and who may now read this case, will see that I followed in one of the severest illnesses that can attack the human frame, the very laws I have laid down, for it was marvellous to all who saw me, my friend, Mr. B., my brother, Dr. —, my brother-in-law, Dr. —, and others, that in one fortnight I rushed into a life-destroying fever and erysipelas, and came out of it without a functional disturbance. Great, nay excessive, weakness and debility was all the trace left behind. Now, there is one more fact to be noticed here, and it may be of great value, my

brother, Dr. —, reasoning in this way, said:—"Now, you, in your sixtieth year, must be very careful. Have an easy carriage to go to your town residence for a few hours a day, and be brought back in the afternoon." Here, again, there is a great want of knowledge of physiology. To get into Uncle Fozzie's stuffed coach, with springs so easy that you may imagine you are not out of your own arm-chair, all having a tendency to produce apoplexy and gout, and if you close the windows, suffocation. "No, no," was my reply. "I shall have my short sharp ride by rail, then I shall get into one of those delicious old London four-wheeled cabs, and have my secretions shaken into their proper places, and get exercise into the bargain, which I cannot take in any other way, for I am too weak; and if I am obliged to shut the windows I shall still have plenty of air. This I shall do night and morning." On the day fortnight of my attack I did this, and have been at my post every day since. On the third day after I was out I had a telegram to go into Kent. I started early, and from one station to the other got my jolting ride in a cab, and then into Kent, and back again to my practice. And let me say this, that when a man of sixty has had such an attack as I had, and once gives up to laziness and Uncle Fozzie's stuffer coaches, and unnecessarily makes himself more an invalid than the nature of the disease has already done, instead of rousing himself on the truest principles, he begins at once to shorten his life ten years.

QUACKS AND THEIR DUPES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—In the letter of "A Preserver of Reason," copied from the *Irish Times* into this week's issue of THE MEDICAL PRESS AND CIRCULAR, the writer gives a painful instance of the moral and physical destruction caused by quackery, the enclosed productions will, I think, give you an idea of what an amount of pocket consumption will most assuredly follow even a short correspondence with such fellows.

The case was simply this:—A young gentleman having read an advertisement in a local paper, wrote to Dr. Watson, Governor of the Lock Hospital, &c. &c., got by return of post a pamphlet (one of the worst of its kind), read it, and, as a natural consequence, thought himself sick; sent a statement of his case and a sample of his urine; then he gets No. 1 letter, which he answers by sending £1 5s., thinking that his troubles were well-nigh ended, and that he would have by return of post a talisman against all the evils to which the flesh is heir to (at least the venereal ones), when lo! back to him comes No. 2 letter, being what Watson calls a statement of items (and very large items my poor verdant friend thought them).

It was at this period your humble servant was consulted, and after a most careful examination of both patient and urine, I must say I have seldom seen a more striking example of what is called robust health.

As for the urine, I trust the Governor of the Lock Hospital may always have as harmless a supply himself. Now, it is quite clear that if this young gentleman had not seen the advertisement in the newspaper in the first instance, he never would in all probability have heard of Dr. Watson, never would have read his filthy pamphlet, never would have paid the carriage of a sample of his urine to London, and sent £1 5s. after it, never would have formed an idea of about the disease for which it is purported to treat him, and, though last not least, never would have spent a fortnight of his life in the most deplorable state of mental prostration; for on my asking him how he could be such a fool as to send £1 5s. without knowing anything about Dr. Watson but his pamphlet, he immediately answered, "When I saw the advertisement in the newspaper and I thought it was all right."

With regard to the measures to be taken, I think your idea of forming a committee of medical and lay gentlemen a most excellent one, and if well worked will surely put a stop

to these disgusting newspaper advertisements and street pamphlets, &c., that are really and truly a disgrace to our country. I, for one, will be most happy to subscribe to the funds necessary for the working of such a committee.—I am, dear Sir, your obedient servant.

T. G. O'SULLIVAN, L.R.C.S.I., &c.  
Resident Surgeon, Limerick Union Hospital.

Limerick, July 12, 1866.

(COPY NO. 1.)

"London, May 26th, 1866,  
1, South Crescent, Bedford-square, W.C.

"SIR,—I have maturely considered your case, and have no hesitation in saying that the chief source of your malady is in a relaxed and debilitated state of the seminal vessels which causes the semen to pass away involuntarily with your urine; the result of this frequent loss will be very evident when you are acquainted with the fact that the loss of one ounce of semen is equal to that of forty ounces of blood.

"This distressing evil is not only calculated to produce all the symptoms complained of, but such is the vital action which exists between the brain and generative organs (*vide* page 25 of pamphlet), that unless this loss of the *most vital* of all your secretions be promptly arrested, the whole system, mental and physical, will be greatly and seriously impaired, and the sexual capacity is destroyed as to render intercourse impossible. Though you are not affected at present with all these serious evils you may daily apprehend their appearance if not at once attended to. To conclude, it affords me much pleasure to be able to acquaint you that by care and attention, and at once adopting my professional instructions, all further ill-consequences will be speedily controlled and your perfect restoration to health secured.

"Local and constitutional treatment of your malady is necessary, a 'Curative Appliance' is therefore necessary.

"These means, if at once applied as I shall direct, will enable me to guarantee a perfect and permanent cure.

"You may rely on my utmost attention to your case on receipt of remittance.—I am, Sir, your obedient servant,  
"(Pro Dr. WATSON) J.M."

(COPY NO. 2.)

"London, July 4, 1866,  
1, South Crescent, Bedford-square, W.C.

"SIR,—The treatment of your case must be local and constitutional, therefore a curative appliance and special remedies to act in conjunction are essential and absolutely necessary in order that a perfect and permanent cure may be effected.

"I subjoin a statement of items, and on receipt of balance rely on prompt attention.—I am, Sir, yours obediently,  
"(Pro Dr. WATSON) J.M."

| Items.             |     |     |        |
|--------------------|-----|-----|--------|
| Curative Appliance | ... | ... | £2 2 0 |
| Special Remedies   | ... | ... | 2 2 0  |
| Usual Fee          | ... | ... | 1 1 0  |
| Balance            | ..  | ... | £4 0 0 |

THE STATE OF THE DRUG TRADE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In an article on "The State of the Drug Trade" in your last number I noticed the following—"Our forefathers would have laughed to deem the idea of one-sixteenth of a grain of aloes or one-eighth of a grain of rhubarb proving an efficient purgative, or of one-fourth of a grain of quinine being effective as a tonic; yet there are patients in whom these doses act effectually, and to whom larger doses are injurious." Now having, during thirty-two years of practice, paid much and close attention to the effects of medicines, I unhesitatingly aver that the eighth of a grain of rhubarb or the sixteenth of a grain of aloes never has proved an effective purgative, and it is only coquetting with homœopathy to assert that it has. I am well aware that such action is often apparent, but on close observation I have always found it to be a coincidence and not an effect. Very naturally so. A man suffering under what is commonly called an attack of bile takes nine small doses of

medicine. He has next day a copious evacuation from his bowels which he attributes to the medicine, but which was really the culminating crisis of his attack; and I have frequently seen the same patient take, the day after, a sharp dose of medicine without any effect. We are too prone to put the *post hoc* for the *propter hoc*, and in no instance more likely than this I have just stated. But let us reflect. A copious evacuation is the natural relief of the attack. Immediately before it occurs the patient takes his quarter of a grain of rhubarb, because he feels poorly. What more natural that to attribute the action to the medicine? I have observed this over and over again; but I again declare that close observation has shown me that such effects are not produced by minute doses of such medicines as aloes or rhubarb. I doubt not the one-fourth of a grain of quinine and one-sixtieth of strychnine are effective doses of powerfully therapeutic drugs. I need not say that there is no analogy.—Yours very truly,

JAMES MARTIN.

#### THE GRIFFIN TESTIMONIAL AND POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me space to offer my warmest thanks to the subscribers of the testimonial presented to me on the 5th inst. To have four hundred gentlemen scattered over the length and breadth of the land thus coming forward is an honour which I highly prize, as it proves to me that the course I have hitherto pursued is one that is approved of by a large body of my medical brethren. To those gentlemen who are not Poor-law Medical Officers I am especially indebted. To those that are, my thanks will be best proved by my devotion to the cause of Poor-law Medical Reform—the accomplishment of which will, I feel confident, be not only beneficial to them, but to the nation at large.

To Dr. Fowler, the Hon. Treasurer and Secretary to the Testimonial Fund, I know not how sufficiently to express my thanks for all the trouble he has taken in the affair. I can only say I thank him very sincerely. To the medical press my acknowledgments must ever be due, for without their aid I could never have been placed in a position to merit the testimonial I have received. The subject of the testimonial (the Good Samaritan) is one which must ever make me feel it to be a religious duty to relieve suffering humanity. As a work of art, the testimonial is nearly perfection. The expression of the countenance of the figures cannot be better. The album of photographs of my medical friends I greatly prize, and yet hope the few gaps in the volume will be speedily filled.

To all and every one my thanks are due.

I shall feel obliged by your insertion of the annexed letter to the President of the Poor-law Board.—I am, &c.,

RICHARD GRIFFIN.

The following gentlemen have forwarded their subscriptions to the funds of the Association:—J. M. Greensill, Martley, 5s.; R. N. Robson, Durham, 10s.; James Hughes, Northwick, 10s.; T. T. Jones, Chesterfield, 5s.; H. M. Simmond, Newington, St. Mary, 10s.; E. G. Verenne, Witham, 10s.; Arthur Pearce, Hartismere, 5s.; T. L. Price, Wigan, 6s.; T. A. Freeman, Hartly Wintney, 10s. 6d.; W. A. Peacock, Halifax, 10s.; John Robinson, Halifax, 10s.; T. L. P. Pugh, Halifax, 10s.

12, Royal-terrace, Weymouth, July 9, 1866.

SIR,—I have the honour to inform you I have in my possession a petition from a meeting of Poor-law Medical Officers, held at the Freemasons' Tavern on July 5th, which I shall be glad to present to you, as President of the Poor-law Board, whenever it will be convenient for you to receive it. It is signed by the Chairman only on behalf of the meeting, but if you desire other signatures, I will quickly procure them. In order that you may at once know its contents, I send you a printed copy. I beg to forward you a summary of the proceedings of the Poor-law Medical

Reform Association, of which I have the honour to be Chairman, in order that you may know what has occurred during the last eleven years, and thus enable you at a glance to understand the question. I also send you a copy of a pamphlet which has been delivered to the Poor-law Board, but which has not been as yet forwarded to the individual members of the House of Commons, owing to the Reform Bill obstructing almost all other business. At page 12 of the pamphlet you will perceive a proposed Bill, which I sincerely trust the Poor-law Board will bring into Parliament. It is not a Bill for a class, although urged upon the country by medical men; it is a bill that will benefit the entire nation. The Right Hon. T. Sotherton Estcourt, when President of the Poor-law Board, said—"I freely and at once admit that I am of opinion that the system of medical relief throughout the country requires alteration." The papers have of late teemed with the abuses of the present system. I respectfully urge upon you to lose no time in taking this subject into your serious consideration. I believe a Poor-law Board Continuance Bill must be brought into the House this session. I pray you to take powers in that Bill to carry out the necessary reforms. I will attend any day you may name, either alone, with three or four other medical men, or a large deputation; but, in the latter case, I shall require ten days' notice to inform my medical brethren of it. At any rate, I trust you will allow me to ask some members of Parliament to accompany me.—I have the honour to be, Sir, your most obedient servant,

RICHARD GRIFFIN.

The Right Hon. Garthorne Hardy, M.P.,  
President of the Poor-law Board.

#### HAY FEVER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your readers will be interested to know that I have lately treated a case of hay fever with the most complete and immediate success by means of Dr. Dewar's sulphur fumigations. I found the patient—a lady—after exposure to the usual cause, in bed suffering from intense headache, suffusion of the eyes, which, as well as the nose, streamed with water, while the sneezing and cough were incessant. The very first fumigation caused the whole of these distressing symptoms to vanish as by magic, and they never returned. I may also mention that an old gouty patient, who is usually most sceptical as to the effects of remedies, fancies he has in his last attack, which is just over, obtained great relief from sulphur fumigations made three or four times a day.—I am, yours, &c.,

M.D.

Edinburgh, July 12, 1866.

### Notes on Current Topics.

AMONG the law intelligence of the daily papers is buried a decision which particularly interests the profession—viz., the liability of charitable institutions to parish rates and other taxes. The Governors of St. George's Hospital appealed against the decision of the parish authorities, who had assessed them at upwards of £4000, and under such assessment charged a rate of £587 18s. 9d. It appears from the petition that the annual subscriptions are insufficient to pay the ordinary expenses of the hospital, and that during the last seven years it has been necessary to sell about £4000 a year of the capital to defray these current expenses, conclusively showing that "the payment of the large annual sum demanded for the poor-rate will probably necessitate a curtailment of the number of patients annually relieved at St. George's Hospital." This institution is probably not the only one similarly circumstanced, and since the decision of the House of Lords in *Jones v. the Mersey Dock*, all our hospitals are liable to parochial rates.

SILKWORM DISEASE.—It is reported by Dr. Drouke

that worms fed upon mulberry trees containing a large proportion of potash, lime, and phosphates are always free from this mysterious disease; and he accordingly advises the phosphates of lime and potassa to be mixed with the manure which is applied to the roots of the trees.

**THE ATLANTIC CABLE.**—The departure of the *Great Eastern* from the Medway, laden with the thread through which it is hoped shortly to flash messages between the Old and New Worlds, has rekindled the public interest in the enterprise, and roused all sorts of inquiries on the subject of the cable and the scientific appliances for laying it and then using it. Perhaps the most important news, provided the cable is once safely deposited in its resting-place, is that just announced respecting the increase of its capabilities. Experiments have been constantly going on with a view of increasing the rapidity with which messages can be sent. By a system of codification, Captain Bolton saves some 35 per cent., and Messrs. Snell and Thomas are reported to have effected an average saving of 40 per cent. The latter gentlemen make the signals of ten words by means of the waves of electricity hitherto required to express six or seven words. Both systems will, no doubt, be thoroughly tried. We may add that all the electricians believe the cable now on the bed of the Atlantic to be in better condition than when it was first submerged, while those in charge of the picking-up machinery are confident that they will be able to find and raise the broken end. Having spliced the shore end, it is expected the great ship will get a clear offing from Valentia. From English and Americans alike earnest wishes for success will follow her across the Atlantic.

**PADDINGTON WORKHOUSE.**—A thorough investigation has just been concluded in this favoured parish which will go far to take away its heretofore superior reputation. Amongst other things, it now comes out that only one qualified nurse had charge of seventy patients in the infirmary, and that the assistant pauper nurses, if not drunken or cruel, were so old as to be incapable of doing their duty, or required bribes to induce them to try. One woman, nick-named "Pots and Pans," took a pillow away from a dying patient, saying "she would go quicker when her head was low." There was no night-nurse, and a poor paralyzed pauper fell twice from her bed to the floor in trying to get up at night. A child was injured by a large iron spoon being forced down its throat by one of the hard-hearted women. Three children slept in the same bed—one of them at the time being affected with hydrocephalus, another with inflamed eyes, and the third with chicken-pox (!). The state of the lunatics was equally untended, and a poor woman is described having bad bed-sores, yet sleeping on a filthy and wet pallet. But in spite of all this, Dr. Anstey declared that, "*knowing its deficiencies, he held that, with one or two exceptions, Paddington Infirmary was the best he had inspected.*"

**URQUHART v. BONNAR.**—This case, an outline of which appeared in our columns some months ago, is again to come before the court of session during the approaching jury trials. It will be remembered that the action was brought by Urquhart, a shoemaker, against Dr. Bonnar; and he sought for a reduction of an assignation of policy of life insurance signed by the pursuer, on the ground of essential error as to its nature and effect, induced through

fraud and misrepresentation or undue concealment on the part of the defender. The case was twice tried by a jury, and in both instances the verdict was against Dr. Bonnar. It is now set down for trial for the third time, and it is not known of course how it will be decided; but we understand that since the death of Urquhart, which happened a short time ago, Dr. Bonnar has made offers of compromise to his friends, which, however, have been refused.

**LONDON HOSPITAL.**—We regret to announce that, on account of failing health, Dr. Parker is obliged to resign his office of physician to this hospital, and his lectureship on the practice of medicine at the College in connexion with it. The opening of the new wing will shortly take place, after which the necessary election will be proceeded with. Several candidates are said to be likely to come forward. Dr. Parker's resignation is a source of regret to all who knew him. His urbanity of manner, his facility in the art of teaching, and his fluency as a lecturer rendered him universally popular and esteemed by his pupils. We sincerely trust his health may be restored, and that he may yet return to his professional labours.

**CHARING-CROSS HOSPITAL.**—There is a vacancy for the office of dentist to this hospital.

**CITY DISPENSARY.**—A physicianship is vacant at this charity by the resignation of Dr. Overend Drewery.

We understand that Dr. William Abbotts Smith has ceased to conduct the editorial department of the *Medical Mirror*, and that Dr. McGowan, lately his colleague, has taken up his pen. The *Mirror* has appeared in a new and improved form, and we anticipate will deserve and receive a more hearty support from the profession than it enjoyed under its late *regime*.

**THE LATE MR. TOYNBEE.**—This distinguished Surgeon has fallen a victim to his love of experimental science. As has been shown at an inquest, he was found dead by his own servant on the sofa of his consulting-room. He had been trying the effect of chloroform and prussic acid vapours to the internal ear, and seems to have suffered some of it to enter the lungs. It is a source of regret to all his numerous friends for so distinguished an ornament of his profession to be thus suddenly called away in the zenith of his hard-earned reputation. He was only 51 years of age when he thus sacrificed his life to his scientific enthusiasm, and has left a wife and nine children to mourn his untimely loss. We are glad to hear, however, that these are amply provided for. Indeed we might anticipate as much from the high position held as a specialist for several years by the lamented deceased gentleman.

**SUICIDE OF DR. WARDER.**—We reported in full last week the "Singular Case of Death of a Physician's Wife," as detailed in the daily papers. It will not be forgotten by our readers that the inquest was adjourned to allow time for chemical analysis of the contents of the stomach. During the week the case has acquired a still more tragic appearance from the suicide of the physician implicated, as will appear from the report of the inquest which has also been adjourned. Dr. Warder was, we believe, formerly a lecturer at the school adjoining St. George's Hospital.

MR. WALTER COULSON is a candidate for the vacancy on the surgical staff of St. Mary's Hospital, Paddington.

## THE CORK POOR-LAW BOARD AGAIN!

THE following extract from the *Cork Constitution* report of the Poor-law Board meeting of the 4th instant shows how a medical man's character is put at the mercy of any ignorant fanatic who may desire notoriety. In this case, however, the Board acted properly. We have corrected a printer's error in the report—the name of Dr. Gardiner, Resident-Surgeon to the Cork Workhouse, having been incorrectly given as “Dr. O'Connor:”—

The Clerk read a letter from the Poor-law Commissioners, enclosing the following, which had been addressed to them by Mr. Parker, and requesting an explanation:—

(COPY.)

“The Green, Passage West, June 26, 1866.

“SIR,—I beg leave to bring under the notice of the Poor-law Commissioners the following complaint made to me this day by Andrew Daly, belonging to Passage, whom I have known for several years to be a well-conducted, sober, and industrious poor man. He stated that he was suffering from pleurisy, pain in the back, with a heavy cough, and after having been examined by Dr. Johnson, the medical officer of this town, on last Wednesday morning, the 20th instant, he was sent by the doctor's directions to the Cork Workhouse Hospital for medical treatment, where he arrived at about twelve o'clock on the same day, taking with him the doctor's order and certificate of disease. On his arrival he felt much weaker, and was taken in the car direct to the gate of the hospital, where he was delayed for upwards of fifteen minutes, and instead of immediate admission he was ordered off to the probationary, where he was again delayed for more than half an hour, and eventually sent to hospital; during this period no medical officer attended him. On leaving the probationary, he found the car which brought him to the house was sent away, and he was so low and weak that he had to be supported by a man as he walked to hospital, where he arrived about one o'clock, and went to bed. No food or refreshment of any kind was offered him until the evening, when he got a pint of milk (which was sour) and half a pound of bread; at nine o'clock, a pint of barley water. That evening passed, also the night, and the next morning, without any medical officer attending him, until between twelve and one o'clock, when Dr. Shinkwin, acting medical officer in Dr. Townsend's place, examined him, who said ‘he did not think there was much the matter with him.’ Daly, suffering from extreme thirst, asked him for something to drink, as he was obliged to drink water, the doctor made no reply, and during that day, Thursday, he (Daly), got neither medicine nor additional drink, except water. The next day, Friday, the doctor asked him how he was getting on, when he replied, ‘It was hard for him to get well when he got nothing to make him strong.’ That day, for the first time, he got a little meat, some porridge, and a half pint of porter, but was refused additional drink in the shape of milk or tea, or anything to assuage his thirst. On the following Sunday night, the pint of barley water he was in the habit of taking, was reduced to half a pint, but, through the kindness of a patient from Queenstown, who knew him, he was brought water from the water closet. On the next day, Monday, finding that he would not get any medicine or proper food, he left the hospital, returned to Passage, and is now under the care of the medical officer in Passage. On inquiring from Daly, he stated that Dr. Gardiner, the resident medical officer, did not see him at all from the first time he entered until he left the workhouse. As the guardian for this district, a sense of duty to the poor alone urges me to ask the Poor-law Commissioners to direct an inquiry to be held into this case with as little delay as possible. I do not intend mentioning the circumstance to the Board of Guardians, because, from experience, I have learned it to be more than useless making any complaint, as, invariably, sympathy is aroused for the officer who neglects his duty, while the case of the poor is ignored, which was clearly shown in the last case I deemed it my duty as a guardian to urge before the Board.—I am, &c.,

“WM. D'ESTERRE PARKER.

“To B. Banks, Esq.,

“Poor-law Commissioners' Office, Dublin.”

The Mayor—Whose letter is that?

Chairman—Oh, you need not ask.

Clerk—It is Mr. D'Esterre Parker's.

High Sheriff—I suppose Dr. Shinkwin and the master and matron will be able to answer for themselves the charges brought against them in that letter; and I suppose Mr. Parker took the usual course adopted by members of this and every other Board before sending forward complaints of any of their officers, and informed Dr. Shinkwin, and the others against whom he preferred charges, of his intention to do so (hear, hear). I know it was my unpleasant duty once to make a complaint against a dispensary physician, but before bringing the matter forward at the committee I wrote to that gentleman, stating the course I was about to take. He came to me to speak to me on the subject, but I told him I could have no intercourse with him about the matter, but he would have an opportunity of answering the charges and explaining them, if necessary, at the committee. I presume Mr. Parker has taken this fair and proper course, in justice to the parties he accuses (hear, hear). I would also ask him, Mr. Chairman, through you, whether he means to stand by his assertion that there was no use in bringing the matter before the Board, as invariably their sympathies were with the officer who was charged with neglect of duty towards the poor.

Mr. Parker—I do, Sir, I brought forward several cases of this nature here and asked for inquiries, and they were refused. I may mention one individual case. A man who was sent in here in a dying state—his name was Nicholas Dunscombe Parker, or Nicholas Parker Dunscombe, I don't know which. The man died, and an inquest was held. It was proved on the inquest that the poor man was grossly neglected. I applied for an inquiry to ascertain the truth of these statements, but an inquiry was refused. I hold now, Sir, that when this present case was represented to me by a man whom I have known for many years to be a truth-telling man, it was my duty to bring it forward and seek to have it investigated, and I ask for an inquiry into the man's case, and the truth of what he represents can then be ascertained. I think it my duty to do so, and my duty I will always continue to do.

Chairman—Will you answer the question put by the High Sheriff, whether you will adhere to the statement in your letter, “I do not intend to mention the circumstance to the Board of Guardians, because from experience I have found it to be more than useless making any complaint to them, as invariably sympathy is aroused for the officer who neglects his duty, while the case of the poor is ignored?”

Mr. Parker—Distinctly, Sir, I stand by it, and will prove it, and very glad to have the opportunity of proving it.

Mr. Keller—Did you consider it your duty to ascertain whether the man's statement was true or false? Did you communicate with the doctor, with the master or the matron, before sending your letter?

Mr. Parker—Indeed, I did not.

Mr. Mahony—I would ask the chairman whether what Mr. Parker says about the neglect he alleges to have been proved on the inquest is correct or not?

Mr. Parker—The sworn testimony of the witnesses on record will prove it. I would make no such allegation if it was not true. I would rather cut off my right hand.

Mr. Mahony—I only want to know what was the decision come to by the twelve gentlemen who were sworn on the inquest. I would like to know the result of their inquiry?

Mr. Parker—The twelve men who composed the jury were most illiterate men (oh, oh, and no, no). I refer you to the public records.

Mr. Mahony—I take it the coroner's inquest absolves us from all responsibility or blame in the matter.

Mayor—When they are going to canonise a man in our church, there is always a person they call “The Devil's Advocate,” whom Mr. Parker in some measure represents at this Board (laughter). His writing to the Commissioners asking for an investigation takes the matter out of our hands, and I propose we take no further notice of it.

High Sheriff—The twelve jurymen in the case alluded to exonerated us completely by their finding. Mr. Parker seeks to prove his statement to the Commissioners, that the Board invariably sympathise with officers who are charged with neglecting duty, by reference to this case. Now, I will put it to the Board whether his allegation is true or not. Is it true that the Board of Guardians have ever refused an inquiry into the conduct of any officer who was charged with neglect of his duty? (hear, hear.) And is it not the fact that the Board have been most severe and strict on their officers? (hear, hear.) It is not becoming

in any man, I don't care who he is, if he hold the highest position in the community, to go behind a Board's back of which he may happen to be a member, and malign that Board and a jury of twelve men sworn to return a true verdict according to the evidence before them (hear, hear).

Mr. Butcher—Certainly.

Mr. Parker—I always will take whatever course I like.

High Sheriff—We always move a vote of thanks to our chairman or any of our officers when their conduct specially calls for it, and it is but fair, on the same principle of giving people their merit, to move a vote of censure on the gentleman who wrote that letter to the Commissioners and could not substantiate it (hear).

Mr. O'Sullivan—What answer are you going to return to the Commissioners? I think it right that an inquiry should be made. It is but fair to the medical officer. If it is true, Mr. Parker deserves credit, and if it is not true it is right the doctor should have an opportunity of answering it. I move it be referred to the house committee (no, no, no).

High Sheriff—My resolution will have nothing to say to that, because the doctor and master will be able to answer for themselves.

Mr. A. Perrier—I think it is not fair to pass such a vote in hot blood. I have heard the guardian who wrote the letter say he can and will substantiate it, and, under the circumstances, I think the passing of such a vote would be premature.

The High Sheriff said he thought he had been explicit enough. Mr. Parker, on hearing this statement as to the man's being neglected, was perfectly justified in writing the letter to the Commissioners, if he had acquainted those whom he accused of his intention. But with reference to the part of his letter stating there was no use in mentioning the matter at the Board, having failed to establish his assertion that the guardians invariably take part with their officers when charged with dereliction of duty, such assertion not being the fact, he thought it was due to the Board to pass a vote of censure on the person who made the statement behind their backs (hear, hear).

Mr. Collins—I think Mr. Parker was perfectly right in calling the attention of the Commissioners to the ill-treatment this man says he had received, and it is a matter for his own good taste and gentlemanly feeling whether he thought it right to do so without acquainting the person he charges or not. But the portion of the letter charging the Board with refusing to institute inquiries into cases of neglect on the part of the officers brought before them is a direct slander on the Board, for they have always been disposed to hold the scales rather against them than with them. I think, therefore, there should not be a moment lost in affirming that this portion of the letter is a slander. I think you ought not for a single moment leave it resting on your Board (hear, hear). We know our own case, and we are prepared to give our opinion here (hear, hear). As to the other portion of it, as Dr. Shinkwin is in the room, this is perhaps the best time to explain it away, if it can be explained away. If he cannot, I think Mr. Parker ought to be acquitted of any blame as far as that goes (hear, hear). But I think this Board would not be acting right to themselves if they delayed a moment in affirming that the reference made to their conduct is a slander (hear, hear).

The Chairman then intimated to Dr. Shinkwin the Board were ready to hear any explanation he had to offer.

Dr. Shinkwin said—Mr. Chairman and Gentlemen, I am very glad you have given me an opportunity of explaining to you about this case. This man, Andrew Daly, was admitted to the Cork Union Hospital on the 20th June. He was admitted after the time I had passed the patients through the probationary ward. On looking at the book I have before me, I find his name under that date, and I find he was sent to nurse Williams's division by Dr. Gardiner. Here is Dr. Gardiner's handwriting, directing the patient to be sent to nurse Williams. In looking into the prescription book I find, in Dr. Gardiner's handwriting also, that this man had been ordered a turpentine stupe to his chest. I saw him on the 21st, the following day. I examined him, and found very little the matter with him, hardly anything in fact. His own expression to me was, he would be all right in a few days. On that day, the 21st, I ordered him number 6 diet, and half a pint of porter. He said it was not worth my while to divide the pint, but to give him the whole of it. (On the next day he was standing near his bed

when I went into the ward. He then remarked to me that he was very thirsty. As he had had a half pint of porter the day before, it naturally struck me he wanted the other half then, and seeing the man strong and healthy-looking I passed on. Touching the complaint Mr. Parker made, that there was not sufficient drink in the hospital, allow me to say, that any of you who go up now, or any other time, will find that there is plenty of drink. There are five gallons of milk and barley-water brought up every morning, and four gallons in the evening. It appears strange to me, that a man able to walk about as he was, should require the assistance of another to bring him a drink of water from the water closet. I regret that for the short time I have been an officer of this Board, a charge should be made against me—a charge, I may say, totally unfounded (hear, hear), and I think it would be fair of Mr. Parker, had he applied to me, or the master, or the nurse, or the matron. There was a variety of ways in which Mr. Parker could satisfy himself about the truth or untruth of the man's statement before taking the course he has adopted. Is there any other question the Chairman wishes to put to me?

Chairman—In my opinion you have fully exonerated yourself (hear, hear.)

Mr. Parker—Was there no medicine required?

Dr. Shinkwin—No.

Mr. Butcher (to Mr. Parker)—Sure, the doctor knows better than you do.

Mayor—The man states he saw no doctor till next day. It appears he did not consider Dr. Gardiner a doctor at all. I think the whole letter of a piece with the statement made about this Board (hear, hear.) You may fairly take the entire letter as one tissue of misstatements.

Mr. Keller—All the fellow wanted was a drink of porter (laughter).

Dr. Shinkwin—It is one of these cases that we get abundance of, where a man has been suffering from a long course of illness outside and comes into hospital, not for medicine, but for food.

The High Sheriff then proposed and Mr. Butcher seconded—

“Resolved—That the statements made in the letter addressed by Mr. D'E. Parker to the Poor-law Commissioners are wholly unfounded, and that the Board express their strongest reprobation of the conduct of Mr. Parker, who has, without any ground whatever, grossly slandered the Board as well as the officers in question.” The resolution was passed unanimously.

Chairman—If this system continues you will not have a respectable officer in the house.

It was then resolved to reply to the Commissioners' letter that the statements contained in Mr. Parker's letter enclosed by them to the Board, were wholly unfounded.

Mr. Parker—Gentlemen, your resolution has proved my case, and time will prove it.

### TRICHINA IN AMERICAN PORK.

THE committee appointed by the Chicago Academy of Science, to examine into the facts concerning the supposed existence of trichina in our pork, have presented a very elaborate report upon the subject. Portions of muscle of 1394 hogs, taken from the different packing-houses and butcher stalls of Chicago, were submitted to careful microscopical examinations, and twenty-eight trichinous specimens were found. The committee conclude that in the hogs brought to Chicago, one in fifty is affected with the disease in a greater or less degree, which indicates with little doubt the startling fact that trichiniasis in pork is even more common in this country than in Germany. But notwithstanding this fact, there is conceded to be very little danger of the disease spreading in this country, as Americans are in the habit of thoroughly cooking the pork before it is eaten. 160° Fahr. is a heat said to be sufficient to destroy the worms. “Again,” says the committee, “by properly salting and smoking the meat for at least ten days, the trichina, should they exist, will certainly be killed. Simple desiccation of the meat, if continued for a period of sufficient length will also kill them. They will never be found alive in old hams for instance (!). On the other hand, mere pickling appears to have very little effect upon these worms. They con-

tend that a strict attention to the feeding of hogs and their confinement in pens where no animal food is accessible, is an infallible preventive against trichiniasis in them. They also endorse the European authorities in reference to the disease, that it is impossible to diagnosticate it from external appearances.

UNIVERSITY OF DUBLIN.—TRINITY COLLEGE.

Examination for Medical Degrees.

Trinity, 1866.

ANATOMY AND PHYSIOLOGY.—PROFESSOR McDOWEL.

1. Enumerate in their order the parts which the omohyoid muscle lies on.
2. Ment on the principal theories which have been held as to the production of animal heat.
3. Describe the course and give the relations of the temporal artery.
4. Enumerate the intrinsic muscles of the larynx, and arrange them according to their actions.
5. Describe the epiglottis, and assign its relations.
6. The composition of the bile?
7. Trace the anterior crural nerve, give its relations, and enumerate its principal branches.
8. Contrast a nerve of the sympathetic and a nerve of the cerebro-spinal system as to their minute structure.
9. Enumerate the structures which maintain the antero-posterior and the transverse arch of the foot, respectively.
10. The minute structure of synovial membrane, and the composition of synovia?

DR. STOKES.

1. What is the cause which, according to Sir Gilbert Blane, is a greater source of the mortality of troops during war than all other causes, including the sword?
2. What are the conditions which render the system more susceptible to the invasion of the so-called zymotic diseases, and less able to resist their influence?
3. Compare the ordinary effects of animal and marsh miasmata on the animal economy.
4. Enumerate the different forms of disease traceable to vegetable malaria.
5. As regards the efficacy of early treatment, compare the diseases induced by animal miasmata with those resulting from true malaria.
6. Give the signs of the scorbutic diathesis; its exciting causes and treatment; and its influence in medical and surgical affections.
7. What are the comparative influences of dryness or humidity of soil as to the production of malaria?
8. What advice would you give to the public authorities, and what prophylactic measures would you recommend to individuals, when an invasion of cholera is threatened?
9. In the construction of the wards of an hospital there are two important points to be attended to—namely, the number of cubic feet of air for each patient, and the amount of ventilation. To which of these would you attach the greater importance?
10. How far can a deodorizer be considered a disinfectant? Enumerate the deodorizers and disinfectants in use.

DR. BANKS.

1. What are the causes of intestinal occlusion?
2. The symptoms and pathology of leucocythemia?
3. Compare the prodromal fever of small-pox, scarlatina, and measles.
4. What are the symptoms, pathology, and treatment of malignant jaundice?
5. What are the diseases in the course of which cardiac inflammations are likely to occur?
6. What are the symptoms, pathology, and treatment of cerebro-spinal arachnitis?
7. What are the physical signs of cirrhosis of the lung?
8. What are the indications for the operation of thoracentesis in pleuritic effusions?
9. What are the indications for the administration of stimulants in typhus?
10. What is the form of epilepsy in which bromide of potassium has been found useful?

CHEMISTRY.—DR. ARJOHN.

1. If the same galvanic current be transmitted successively through water, hydrochloric acid, and a solution of

sulphate of sodium, what are the relative quantities of these compounds which will undergo electrolysis?

2. Explain, in the case of a Nairn's machine, how the positive conductor becomes charged; also why, in order to bring the machine into action, one or other of its two conductors must be uninsulated.

3. What is the ordinary method of developing chlorine gas, and the reactions which ensue when the gas is conducted into a strong solution of potash?

4. Copper may be converted into a soluble salt by sulphuric or by nitric acids; explain the action of the acid in each of these cases.

5. How is liquor potassæ made? Mention also the impurities usually present in it, the experiments by which they are detected, and the manner of removing them.

6. Mention the composition of the chief ore of antimony, how it is converted into antimoniæ terchloridi liquor, and how from this latter a pure oxide of antimony may be obtained.

7. Write the formula for urea: mention how it is usually extracted from urine, and the advantage which oxalic acid has over nitric when used in the latter process.

8. Write the formula of valerianic acid; explain how it is made artificially, and converted into valerianate of zinc.

9. Name the leading proteinic compounds, and the percentage of nitrogen occurring in each; state also how the protein of Mulder may be extracted from them; and mention the method suggested by Liebig for showing that they include unoxidized sulphur as a constituent.

10. Write the formula for chloroform; explain how it is made, and how it is deprived of spirit, hydrocarbons, and water.

MATERIA MEDICA.—DR. AQUILLA SMITH.

1. Give the characters of the seed of "Strychnos Nux Vomica." Name the preparations made from the seed, and state the dose of each for an adult.

2. How much lime is held in solution in one fluid ounce of "Liquor Calcis Saccharatus;" and how much in one fluid ounce of "Liquor Calcis?"

3. State the quantity and kind of cinchona bark in one pint of "Tinctura Cinchonæ Composita;" and in one pint of "Tinctura Cinchonæ Flavæ."

4. Name at least three of the tinctures in the British Pharmacopœia which become turbid on the addition of water, and the colour of the precipitate in each case.

5. What are the constituents of "Pilula Rhei Composita," and how much rhubarb is in ten grains of the mass?

6. Give the botanical name of the plant, and the part of the plant from which "Resina Podophylli" is prepared. Why is hydrochloric acid used in preparing the resin? State the therapeutic action, dose, and mode of administration of the resin.

7. How much "Tartarated Antimony" is in one fluid ounce of "Vinum Antimoniale?" and how much "Tartarated Iron" in one fluid ounce of "Vinum Ferri?"

8. Give the general characters of the gum-resins, and a description of one of them, with its action, dose, and mode of administration.

9. What preparation of "Catechu Pallidum" is in the Pharmacopœia? Describe the drug, and give the name of the plant from which it is obtained.

10. Write a prescription in Latin for an eight-ounce mixture, containing two vegetable diuretics, and one diuretic salt, with directions for its administration.

DR. WRIGHT.

1. Enumerate the different forms of inflorescence in which the flowers are sessile on (a) an elongated and on (b) a shortened or depressed axis.

2. Enumerate some of the more striking modifications of persistent Bracts.

3. Describe the calyx in Delphinium, Helleborus, Anemone, Hyoscyamus, Eschscholtzia, and in Physalis.

4. Describe the flower of Sarothamnus Scoparius.

5. Enumerate the different modes of dehiscence.

6. Describe the different parts of the pericarp in an Achene, Drupe, Pomum, Berry, and Hesperidium.

7. Describe a strawberry, raspberry, and mulberry.

8. Enumerate the different layers of bark met with in the common oak.

9. Refer the Plant A on the table to its natural family and genus.

10. Describe the Plant marked B as to its stem, leaves, inflorescence, and flowers.

## EXECUTION OF THE NEW MEDICAL WARRANT OF HER MAJESTY.

WE learn from an authoritative source that, at the Council held at Windsor on Friday week last, a Warrant, embodying the Recommendations of the late Committee on the Army and Navy Medical Services received the sanction and signature of Her Majesty. If our information be accurate, we offer our most sincere congratulations to the profession. By this Warrant, if it be honestly and justly carried out by the Horse Guards and Admiralty, a field worthy of their acceptance and cultivation is thrown open to medical men.

## Medical News.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**---At a general meeting of the Fellows held on the 9th inst. the following Members of the College were duly admitted Fellows of the same:—

Andrew, James, M.D. Oxon., Russell-square.  
Buchanan, George, M.D. Lond., Harley-street.  
Chadwick, Charles M.D. Edin., Leeds.  
Falconer, Randle Wilbraham, M.D. Edin., Bath.  
Fox, Wilson, M.D. Lond., Cavendish-square.  
Hewitt, William Morse Graily, M.D. Lond., Berkeley-square.  
Ogle, William, M.D. Oxon., Clarges-street, Piccadilly.  
Southey, Reginald, M.D. Oxon., Montague-place, Russell-square.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**---The following gentlemen have just passed the Preliminary Examinations in Arts, &c., for the Fellowship of the College:—

Edward Bellamy, E. L. Fenn, J. W. Howard, Edward Smith, W. M. Vores, C. H. Allfrey, and F. W. Braine.

And the following for the Membership:

M. S. Allen, F. C. Batchelor, Herbert Curtis, J. W. Anningson, Alexander Cartwright, Richard Aubrey, J. J. Allen, William Beesley, A. E. Davies, C. W. Evans, George Millson, J. E. Clarke, Edward Bovill, E. R. L. Crespin, F. D. Grayson, William Garratt, Charles Glasier, C. B. Plowright, F. H. Edmonds, Edward Barber, C. J. Davis, Joseph Farrar, J. E. C. Ferris, Adam Young, John Booth, Robert Caldecott, F. H. Bodman, J. E. Gabb, E. H. Gibbon, Chas. Gosse, Thomas Harvey, H. A. Leapingwell, G. A. Jennings, H. W. Hewetson, F. W. O. R. Jones, J. B. Lyth, L. J. King, Henry Gibbs, W. C. Heane, J. L. Leckie, S. A. Julius, T. J. Jones, W. L. King, W. H. Davies, J. A. Lewis, R. J. Cope, W. A. Dunn, B. P. Morrison, E. C. Ling, H. E. Hudson, Edwin Price, A. M. Palmer, H. C. Lacy, G. O. Risdon, E. C. Rogers, Edwin Hemsted, W. A. Satchell, E. C. R. Roose, J. G. Roberts, Tom Robinson, E. G. Roche, C. W. Price, W. H. Thompson, M. A. B. C. Stevens, C. W. Harvey, T. H. F. Tothill, F. G. Ree, H. O. Taylor, T. C. Temple, C. W. Vickers, S. J. Wolton, J. Oliver, C. L. Vasey, Wadhwan Robinson, Henry Thompson, A. D. Wray, R. L. Verley, W. J. Powell, C. W. Chinery, William Rendall, Alfred Dix, R. H. Paterson, W. M. Rosten, G. E. Rundle, Hugh Acock, K. F. Sylvester, H. T. Tatum, G. D. Thane, J. H. Thomas, S. W. Fitt, Arthur Lascelles, Thomas Dewhurst, Edward Elsmere, and William Beaton.

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**---Licences to practise Medicine were granted to the following gentlemen during the months of April, May, and June, 1866:—

|                                    |                                   |
|------------------------------------|-----------------------------------|
| W. B. Peebles, B.A., M.B., Dublin. | C. R. Enright, Limerick.          |
| John B. Kelly, Drogheda.           | Henry Dwyer, Dublin.              |
| John O'Hanlon, Dublin.             | William B. Anster, Dublin.        |
| Robert F. Maunsell, Dublin Castle. | John Campbell, B.A., M.B., Dublin |
| William I. Wheeler, Kildare.       | William C. Roe, Dublin.           |
| Malachy J. Kilgarraff, Dublin.     | Patrick T. Lyster, Athlone.       |
| P. O'Neill, L.R.C.P. Ed., Kildare. | William P. O'Leary, Cork.         |
| G. C. Chesnaye, Allahabad.         | Charles P. Tomkins, Cork.         |
| Francis Egan, Dundrum.             | Henry Nugent, Waterford.          |
| Adam Clarke, Fermangh.             | W. J. Martin, M.D. St. And., Dub  |

The following gentlemen obtained the Midwifery Diploma during the same period:—

|                            |                        |
|----------------------------|------------------------|
| J. B. Kelly, Galway.       | Adam Clarke.           |
| Edward J. Kelly, do.       | Henry Dwyer.           |
| Charles Fryer, Southport.  | Cornelius R. Enright.  |
| William Ireland Wheeler.   | Patrick Thomas Lyster. |
| Malachy Joseph Kilgarraff. | Charles Payne Tomkins. |
| Patrick O'Neill.           | Henry Nugent.          |
| Francis Egan.              |                        |

**APOTHECARIES' HALL.**---The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 5th inst.:

Lloyd, Evrn, Cross-inn, Llanelly.  
Low, Alexander James, St. Belares, Jersey.  
Needham, Frederick, York.  
Place, Thomas Lloyd, Wickham Market, Suffolk.  
Taylor, Isaac, York.  
Underhill, Francis William. Tipton, Staffordshire.

The following gentlemen also on the same day passed their first examination:—

Benjamin Walker, Guy's Hospital; William James Bennett, ditto; Charles Trew Winckworth, Westminster Hospital; George Amsden, King's College.

**UNIVERSITY OF ATHENS.**---In this University there were, during the last session, two hundred and fifteen students of medicine.

**GLASGOW MEDICAL SOCIETIES.**---The Medical and Medico-Chirurgical Societies of Glasgow have wisely undergone the process of amalgamation.

**SIR JAMES CLARKE.**---The Queen has appointed Sir James Clark, Bart., M.D., to be an Ordinary Member of the Civil Division of the Second Class, or Knight Commander of the Order of the Bath.

**W. E. WILKINSON, L.R.C.S. Ed.,** has been appointed Surgeon to the Constabulary of Glasson, Ballykeirnan, and Baylin, county Westmeath.

**THE MEDICINA,** a Naples journal, threatens to publish the names of all its subscribers who are in arrear.

**MR. QUAIN** has resigned the Surgeoncy of University College Hospital, and also the Professorship of Clinical Surgery at University College.

**DR. GULL** has resigned the physicianship of Guy's Hospital.

**DR. A. P. STEWART** has resigned his office of Physician to the Middlesex Hospital. He has held office there for about twenty years. His natural successor is Dr. Murchison; and candidates Drs. Tatham, Liveing, and Fenwick, are in the field for the vacancy which will be made by Dr. Murchison's promotion.

**THE POLLUTION OF RIVERS COMMISSION.**---The Royal Commissioners are at present engaged in making a personal inspection of the river Ouse and the surrounding neighbourhood, previous to taking evidence on the spot, which will not be till the first week in October.

**THE CURÉ of Neuri-sur-Baraujen** died some days ago from the effects of a sting in the lip from a venomous fly.

The deaths in London last week were very little over the average. Diarrhoea is on the increase, but is not excessive for the beginning of July. Cholera shows no tendency to become epidemic. The thermometer in the sun last Thursday reached 147 degrees.

**THE EMPRESS AT AMIENS.**---Great excitement has been created in France by the visit of the Empress Eugénie to Amiens. The cholera has been raging there to such an extent that the assizes were indefinitely postponed. Eighty deaths a day have been recorded, and it is said that no medical records exist of any European city having been so devastated by cholera as Amiens has been for the last three weeks. The Empress arrived in Amiens at half-past ten in the morning, and then proceeded to the Hôtel Dieu, visiting all the cholera wards, and thence proceeding to the various charitable refuges, &c., thus passing the whole day. Whatever practical utility there may be in such a visit, there can be but one opinion as to the noble self-devotedness, sympathy, and courage that prompted it. It is said that when complimented by a French Marshal on the courage displayed by her on this and a previous similar occasion, her Majesty replied, "Monsieur, c'est notre manière d'aller au feu." The Municipal Council of Amiens have voted an address of gratitude to her for her visit, and ordered that a commemorative medal in gold should be sent to her. The last sanitary report gives forty deaths by cholera on Monday.

It is a significant fact that the functionaries of the German Association of Naturalists and Physicians have sent out circulars announcing that the forty-first meeting, which was to be held in September next, will not take place. This will be a disappointment for those members of our scientific societies, who had planned to take part in the very agreeable proceedings which have usually characterized the meetings of the Association.

**FATAL SOMNAMBULISM.**---An inquest was held at Devonport on Wednesday on the body of Joseph Colclough, a soldier in the 94th Regiment. On Sunday morning the

sleepers in the Raglan barracks were aroused by cries of distress, and on going out of the barrack-room they found the deceased lying on the ground suffering from severe injuries. It is supposed that the deceased, who had gone to bed quite sober, had walked in his sleep and fallen out through a large window which had been left open. He died from his injuries on Wednesday afternoon. The inquest was adjourned for the attendance of medical witnesses.

**UNSCIENTIFIC AND FATAL SURGERY.**---Friday, at the Norfolk Assizes, a bone-setter named Bennett was indicted for the manslaughter of James Squires. The deceased, who was 66 years of age, had put his shoulder out, and went to the prisoner to have it set. The latter employed several men to pull at the arm, and these did their work so vigorously, that the muscles were torn assunder and important blood vessels ruptured. The man died the same evening. His lordship, in summing up, pointed out that the fact was that more force had been used than was necessary or intended; and that while on the one hand it appeared that the prisoner was grossly ignorant on surgical matters, on the other there was no imputation of negligence against him. The jury returned a verdict of guilty, and the prisoner was ordered to pay a fine of £50, or to go to prison for six months if the fine was not paid before the next goal delivery for the county.

**ARTISANS' DWELLINGS AND PUBLIC HEALTH BILLS.**---Friday afternoon, Mr. Walpole received his fifth deputation, at the Home Office, in reference to the Artisans' and Labourers' Dwellings and Public Health Bills, which was from the vestry of St. Marylebone, and was introduced by Mr. Harvey Lewis, M.P. It consisted of Mr. Chubb, Mr. Poland, Dr. Richardson, Mr. Tavener, Mr. Tyler, Mr. Harlowe, and Mr. Surridge, accompanied by Mr. W. E. Greenwell, vestry clerk, and Dr. Whitmore, medical officer of health. The objects of the deputation having been urged with great force by Mr. Chubb, Mr. Poland, Mr. Whitmore, and others, Mr. Walpole said the deputation would not expect him to give any decided opinion on the subject that had been brought before him, but it should receive his best attention. The deputation, having thanked the Home Secretary, then retired.

**THE SUICIDE'S OBSEQUIES.**---On Thursday evening Dr. Warder's remains were interred without the usual rites. The spot selected was the parochial cemetery on the Lewes-road, near the Preston Barracks, and at half-past ten on Thursday night the burial was accomplished in the briefest imaginable time. The nothingness of the ceremony is worth a word. A grave had been dug in the chalk; a hearse arrived with a common coffin; three seconds later the coffin was at the side of the grave; and in three other seconds it was at the bottom of the excavation, and three other seconds heard the rattle of the clods on the elm boards of the doctor's *domus ultia*. The only light thrown on the transaction was that which streamed from the bull's-eyes of a couple of police lanterns. About 100 people witnessed the novel ceremony.

The Medical men *en masse* of the North London districts have just addressed an energetic letter to the *Times* denouncing in no very measured terms, the verdict and sentence in the recent case of rape, "The Queen *versus* Toomer." The letter goes on to say—"We desire to place on record our earnest protest against the decision of the jury, and the sentence of the judge in this case. . . . There has been a frightful miscarriage of justice here, and we call on you, in the name of justice, to use your all powerful voice to secure for this prisoner a remission of the dreadful sentence (fifteen years) passed on him for the commission of an offence which was not rape."

**NAVY SURGEONS.**---We believe we can safely announce that at the Council held at Windsor yesterday week, the Queen signed the order confirming the suggestions made by Sir Alexander Milne's Committee, for improving the pay and position of the Medical Officers of the two services.—*Army and Navy Gazette.*

MR. QUAIN'S resignation of the offices of Special Professor of Clinical Surgery at University College and of Surgeon to the Hospital has been accepted with regret by the Council, which has decided that in future the Special Professorships of Clinical Medicine and Surgery shall be the Holme Professorships.

GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.  
SIR,—The following subscriptions have been further received on behalf of the above fund, the balance-sheet of which I hope to forward next week:—

|                                                                   |         |
|-------------------------------------------------------------------|---------|
| H. M. Simmonds, Esq., Newington                                   | £0 10 0 |
| Thomas Harper, Esq., Plymouth                                     | 0 5 0   |
| Thomas Taylor, Esq., Braintree                                    | 0 10 6  |
| John Harrison, Esq., Braintree                                    | 0 10 6  |
| George Greaves, Esq., Chorlton                                    | 1 1 0   |
| Henry Bencraft, Esq., Southampton                                 | 0 10 6  |

| Dr. J. H. Lloyd, Anglesey                                         | 1 0 0   |
| Dr. T. Orme Dudfield, St. Margaret's, and St. John's, Westminster | 0 5 0   |
| W. B. Brown, Esq., Windsor                                        | 0 10 0  |
| Messrs. Clark and Wilton, Sutton                                  | 1 1 0   |
| And previously announced                                          | 186 6 9 |
| Received at <i>Lancet</i> Office                                  | 13 11 6 |

—Your obedient Servant,  
ROBERT FOWLER, M.D.,  
Treasurer and Hon. Sec.  
145, Bishopsgate-street Without, July 10, 1866.

Appointments.

LONDON.

W. DRAPER, M.R.C.S., has been appointed Resident Obstetric Assistant to the Middlesex Hospital.  
REES LLEWELLYN, M.R.C.S.E., has been appointed House-Surgeon to the London Hospital.  
H. A. PITMAN, M.D., has been appointed Consulting Physician to St. George's Hospital.

PROVINCIAL.

E. HILL, M.R.C.S.E., has been appointed Assistant House-Surgeon to the Kent and Canterbury Hospital, vice W. Rigden, M.R.C.S.E., resigned.  
G. H. MADELEY, M.R.C.S.E., has been appointed House-Surgeon to the Coventry and Warwickshire Hospital, vice H. C. Lawrence, L.R.C.P.L., resigned.  
W. J. MERLIN, L.R.C.P., has been elected Medical Officer and Public Vaccinator for the Sutton District of the Ely Union, Cambridgeshire, vice Wm. Bullers Buller, M.R.C.S.E., resigned.  
G. C. MILLAR, M.D., has been elected Medical Officer to the Hackney Union Workhouse, vice D. De Berdt Hovell, F.R.C.S.E., resigned.  
W. PARKINSON, M.R.C.S.E., has been re-appointed one of the Hon. Surgeons to the Bradford Infirmary and Dispensary, upon retiring after ten years' service in accordance with the rules.  
J. RILEY, M.R.C.S.E., has been elected a District Surgeon to the Salford and Pendleton Royal Hospital and Dispensary, Manchester, vice T. Sutton, L.R.C.P.Ed., resigned.  
C. ROBERTS, M.R.C.S.E., has been appointed Surgeon to the House of Correction at Northallerton, Yorkshire, vice F. R. Gibbes, M.R.C.S.E., resigned.  
H. RUNDLE, M.R.C.S.E., has been appointed House-Surgeon and Secretary to the Hants County Hospital, Winchester, vice A. B. Adams, M.R.C.S.E., resigned.  
J. E. SMITH, M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Hertfordshire District and the Workhouse of the Hay Union, vice Procter, resigned.  
R. SOUTHY, M.B., has been appointed Hon. Physician to the Metropolitan Convalescent Institution, Walton-on-Thames, vice T. Dixon, M.D., resigned.  
J. N. TERRY, M.R.C.S.E., has been re-appointed one of the Hon. Surgeons to the Infirmary and Dispensary, Bradford, Yorkshire, upon retiring after ten years' service in accordance with the rules.

IRELAND.

M. BAREN, M.D., has been appointed Surgeon to the Constabulary, Labasheeda, county Clare, vice J. Finucane, L.R.C.P.Ed., deceased.  
J. CAVET, L.R.C.P.Ed., has been elected Surgeon to the Leper Hospital, Waterford, vice J. P. Mackesy, M.B., deceased.  
M. J. SHERIDAN, M.D., has been elected Medical Officer for the Oulart Dispensary District and the Fever Hospital of the Enniscorthy Union, county Wexford, also Public Vaccinator and Registrar of Births, &c., vice M. J. Cartan, L.R.C.S.I., deceased.

SCOTLAND.

S. BUCHANAN, M.D., has been appointed Surgeon (*pro tem.*) to the Clyde Police, Glasgow, vice E. Milner, M.D., deceased.  
J. G. WILSON, M.D., has been appointed one of the Physicians to the new Dispensary for Women and Children in connexion with the Glasgow Lying-in Hospital.

WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING JULY 7TH, 1866.

### LECTURES

ON THE

### NATURE, CAUSES, AND TREATMENT OF DYSPEPSIA.

Delivered at the Queen's Hospital, Birmingham.

By BALTHAZAR W. FOSTER, M.D., F.L.S.

MEMBER OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON; LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO THE QUEEN'S HOSPITAL, PROFESSOR OF CLINICAL MEDICINE IN QUEEN'S COLLEGE, AND OF THERAPEUTICS AND MATERIA MEDICA IN SYDENHAM COLLEGE, BIRMINGHAM; PHYSICIAN TO THE GENERAL DISPENSARY, BIRMINGHAM.

### LECTURE V.

GENTLEMEN,—In our review of the oral and gastric stages of digestion, we have seen the manner in which the saliva and the gastric juice act upon the saccharine and albuminous portions of our food, and we have noticed that these fluids have no share in the transformation and preparation of fat.

The chyme as it passes from the stomach contains much converted albumen and some starchy matters in a state of solution; the oleaginous substances have simply their investing membranes acted upon, but are themselves chemically unchanged. In the small intestine, with its varied secretion, we have to look for the converting agents which render fat fit for absorption, and to which we must attribute the digestion of the starch and albumen which have escaped conversion in the stomach. In the small intestine three fluids are poured out to mingle with the food, and to help in its assimilation—the pancreatic juice, the bile, and the secretion from the intestinal glands—the succus entericus.

The *pancreatic juice* first claims our attention, for of late years it has been the subject of much investigation by physiologists, and to the elucidation of its action some of the most brilliant of his experimental inquiries have been devoted by Claude Bernard.

The pancreas (similar in structure to the salivary glands) begins, some thirty minutes after the commencement of gastric digestion, to pour into the intestine a clear, viscid, alkaline fluid, containing a peculiar coagulable substance called pancreatine. Mingling with the descending stream of chyme, this fluid reacts upon its constituents, but chiefly upon the unaltered oleaginous materials.

Fats no longer escape conversion, they are emulsified and chemically changed by this secretion. If we mix healthy pancreatic juice with fat out of the body, and maintain a temperature sufficient to liquify the fat, we observe that when stirred the fluids combine, and form together, by what we term the emulsification of the fat, a substance like chyle. Moreover, they do not separate when left alone for a considerable time, as is the case with an emulsification formed by bile, saliva, serum, and other fluids. This action of the secretion of the pancreas is, however, not limited to the mere division and emulsification of the fat; it is also marked by a chemical change—the fat is separated into glycerine and its fatty acid, and the mixture, previously alkaline, betrays a slightly acid reaction. No other fluids in the economy, according to Bernard, can effect this; and only after the chyme has mingled with the secretion do fatty substances enter the lacteals. This point has been much contested, and it is now considered probable that some of the small duodenal

glands may aid, to a small extent, in the conversion of fatty foods.

The starch, unconverted by the action of the saliva, but rendered soft and easy to act upon by its delay in the stomach, passes into the duodenum, suspended in the chyme, to meet with rapidly converting agents in the pancreatic fluid and the succus entericus.

The ferment contained in these secretions rapidly changes the starch into grape sugar, and thus renders it capable of being absorbed. The part played by the intestinal glands is feeble, and to the pancreatic juice is chiefly due the conversion of starch and fat. Pathology supports this view by the fatty stools characteristic of diseases of the pancreas, and extirpation of the gland has been found to be followed by the excretion of a considerable quantity of unchanged starch and fat. The function of the pancreatic juice is, however, triple in its nature, and it seems to be poured forth as the last agent necessary to form that elixir vite—chyle; for not only does it play an important part in the conversion of the fat and starch, but it also acts upon the unchanged albumen, which, suspended in the chyle, has passed onward from the stomach. This action only takes place under certain conditions—viz., first, that the albumen should have previously undergone some preparation, by gastric juice; secondly, that the pancreatic juice should be mixed with bile; and thirdly, that the reaction of the solution should be slightly acid. Now these three conditions are readily fulfilled in healthy digestion; the albumen meets the pancreatic juice only when it has escaped the gastric juice, and when much of it has already been converted into parapeptone; the bile also mingles with the pancreatic secretion as it is poured into the intestine, and the acid character of the chyme supplies the third condition. When, however, any cause interferes with the existence of a sufficiently acid reaction in the chyme itself, the action of the pancreatic juice on the fatty matters sets free enough acid to supply the necessary quality.

From a review of the experiments which have been made by many observers with reference to the converting power of this secretion over albumen, we must concur in the opinion, that the pancreas plays an important part in dissolving the albumen and the parapeptone which have escaped the action of the stomach. Schiff, in his experiments on this subject, points out an interesting relation with reference to this action existing between the pancreas and spleen. The extirpation of the spleen, in his observations, invariably deprived the pancreatic juice of its converting power over albumen, but, at the same time, the secretion of pepsine by the stomach was more copious.

The supplementary part which the pancreatic juice plays to the other digestive fluids, and the importance of its special action upon fatty foods, make any derangements, either in the quality or quantity of its secretion, of much consequence to the economy.

In all experiments that have been made upon this gland, one of the most striking features is the extreme ease with which the healthy secretion is disturbed. The viscid, alkaline, coagulable fluid is replaced by a thin watery liquid, still alkaline in its reaction, but *no longer containing coagulable organic matter*, and consequently no longer capable of acting upon fatty food. Another fact worthy of notice is, that the secretion no longer *intermits* between the digestive acts, but the altered secretion pours *continually* into the intestine. Such serious changes are brought about, we are led to believe, by functional nervous disturbance, and to the branches of the sympathetic system which preside over the function of this gland, we must refer this abnormality.

Bernard has well pointed out for our guidance that below the pylorus we no longer have secretion governed as in the stomach by both the cerebro-spinal and ganglionic systems, but to the great sympathetic alone do the glands connected with the intestine answer. Paralysis of the branches of this system supplying the intestines is ever followed by increased secretion from the pancreas and other intestinal glands.

Inflammatory conditions of the pancreas, originating either in its own structure, or secondarily affecting the gland, as is most common, have the same result.

We can easily understand how serious to the digestive process is any derangement of secretion such as we have mentioned. No longer are the fatty portions of our food converted and absorbed; but, on the contrary, they pass away with the excreta, and the system languishes for its chief respiratory food. But the evil ceases not here, the altered secretion acts upon the unconverted starchy matter, and being greater in quantity, and flowing constantly into the intestine, the action is no longer bounded by the normal limits, glucose is continuously converted into lactic acid, and the intestines are distended and irritated by CO<sub>2</sub>, H<sub>2</sub>, and other gases. I need hardly tell you that the parapeptone and unconverted albumen, mingled in the chyme, are also not digested, but passing away with the fæces, are lost to the system.

On the other hand, conditions are well known to us in which we have reason to believe that the functions of the great salivary gland of the abdomen are by no means as active as they should be, and we find our patients labouring under various dyspeptic symptoms, the chief and most characteristic being an inability to digest fat. We often call this fatty dyspepsia, and you have frequently had it pointed out to you as one of the common symptoms of the dyspepsia of phthisis. Under these circumstances there is much reason to believe that the stomach acts very thoroughly, possibly for a time even more actively than in health, upon the albuminous food, but the fatty matters are scarcely, if at all, assimilated, and the starchy substances are partly undigested.

Arrangements of this kind cannot exist long without producing serious disorder in the system, and they call for well-directed action on the part of the physician. Of late, attempts have been made, when the pancreas is supposed to be inactive, to supplement its action by the administration of extracted pancreatine and pancreatic emulsion. This was first suggested by Dr. J. A. Flés; it has since been ably advocated in this country by Dr. Dobell of London. But I would have you first try the effects of remedies upon the pancreas itself, for Bernard's experiments teach us that we have one if not two valuable drugs in *ether* and *iodide of potassium* at our command, by which we can stimulate the secretion of this gland. The action of either in increasing the flow of pancreatic juice is so marked that Bernard used it frequently in his experiments to stimulate the gland, and always with success. Of this subject I shall have more to tell you in a future lecture; I merely indicate the fact now for your consideration. We have seen how the pancreatic secretion plays an important part in the assimilating process, and we have glanced at the manner in which dyspepsia is produced by the disorder of its functions. Before leaving this part of the subject, however, let me add, that in those states in which the flow of pancreatic juice is continuous, gastric digestion is occasionally impeded by the regurgitation of the secreted fluid into the stomach.

(To be continued.)

## RICHMOND HOSPITAL.

### CLINICAL SURGICAL LECTURES.

By JOHN HAMILTON,

SURGEON TO THE RICHMOND HOSPITAL, AND TO SWIFT'S HOSPITAL FOR LUNATICS.

#### LECTURE I.—PHYMOSIS.

We have had during the last two months six cases of phymosis in the hospital.

1. A man, in No. 6 ward, with inflammatory phymosis, from phagedenic chancre, which perforated the prepuce, requiring the prepuce to be slit up. When the chancre was exposed it was the size of a florin. He was put under mercury till salivation, and the improvement in the sore

was so rapid that he left, after having been in sixteen days, with a small granulating ulcer only requiring water-dressing, the prepuce merely showing a small slit where the incision had been made.

2. In the opposite bed, in No. 6, George Campbell, a dirty, half-witted fellow, with very bad inflammatory phymosis, the penis enormously enlarged, red, and œdematous; profuse, fœtid, oily-brownish discharge, tinged with blood; exquisitely tender. His general aspect sallow and wretched. There was a black spot on the dorsum of the prepuce, evidently over a phagedenic sore. Mr. Henry, the resident pupil, in my absence, seeing there was no time to be lost, immediately on his admission did what he had seen me do in the previous case, slit up the prepuce through the black spot, and came down on a large phagedenic chancre. He was put on calomel and opium. I saw him the next morning. There was a large flap of thickened prepuce hanging down, which I desired Mr. Henry to cut off, effecting complete circumcision. His mouth became sore, his general health much improved, and he left quite well in about a month.

3. A young man, in No. 8 ward, with phymosis, not large nor very inflammatory, but he could not draw back the foreskin to exhibit the chancres. There was profuse yellow discharge, and when the prepuce was a little retracted, a portion of a chancre was exposed at the lower edge of the orifice of the urethra at the frænum, and evidently extending down. He had enlarged glands in both groins, many and indolent. The chancre could be felt in the situation of the frænum, through the prepuce, hard. Five grains of grey powder were given three times a day, and injections of water, and afterwards of black-wash, ordered. His mouth became sore; he could then draw back the foreskin, though with some difficulty. Three chancres became visible—a large one over the frænum, which it had destroyed, and two others, small and granulating, on the glans. The large one was still unhealthy; it was touched with the solid nitrate of silver decidedly. All the sores were healed in four or five days, except a small portion of the upper part of the large one, but it healed entirely in two days after. Two of the glands—one in each groin—suppurated, were opened, and discharged some thick yellow pus; they gave no further trouble. He left the hospital to go to his friends, the glands in the groin still swollen and discharging a little.

Jan. 2, 1866: I saw him two months after for a gonorrhœa, but he was completely well of the syphilis.

4. A young policeman, with phymosis, not inflammatory, but arising from indurated chancres round the orifice of the prepuce—a bubo in the left groin. He left the hospital of his own accord a few days after admission.

5. A man, in the new ward, with acute phymosis and phagedenic chancre. The prepuce was slit up on the dorsum, where the chancre was felt to be. He was brought under the influence of mercury, and left the hospital at the end of three weeks quite well, a small notch alone indicating where the incision had been.

6. In No. 5 ward, a patient with chancres round the orifice of the prepuce and consequent complete phymosis. After slight salivation, the application of, first, the saturated solution of the nitrate of copper, and afterwards the use of the solid nitrate of silver, the chancres healed, and at the end of a month he could draw back the prepuce, but there was some induration at the orifice.

While these cases are fresh in your minds it may be profitable to consider the different forms of phymosis which the surgeon meets with, and the kind of operation suited to each. We are oftener called to treat that division which is called accidental than congenital cases of phymosis. I have never met with the prepuce entirely closed, as described by Petit, where the infant, soon after birth, is observed to be restless, irritable, and constantly crying, and the linen dry; and on examination the prepuce is found swollen out, transparent, and full of urine; a puncture with a lancet readily remedies the distress for the time.

Others at birth have the orifice of the prepuce so very small that the water not readily getting through it at each time of passing water the urine distends the prepuce, and finally irritates and excoriates its lining membrane and that covering the glans, and the two raw surfaces adhere, forming one of the most difficult cases of phymosis for operation, as it is very hard to divide the prepuce without wounding the glans, and after the division is accomplished there is still a most difficult and painful operation to perform—that of dividing the adhesions and peeling off, as it were, the prepuce from the glans. My colleague, Dr. Banks, sent me, some years ago, a case of this kind, where the adhesions, except in one or two points, were so close that, with difficulty, at one spot I could get in a small director between the prepuce and glans. I divided the prepuce, and afterwards, partly by cutting and partly by tearing, I separated the prepuce from the glans. The case terminated well. The contraction of the orifice of the prepuce not only prevents its retraction, but gives rise to such irritation that the surgeon is imperatively called on to operate.

Master C., æt. 12, was observed by his father to make water often and with pain, and it was found that the orifice of the prepuce was so reduced in size that when he tried to make water it only came drop by drop, while the prepuce itself swelled out like a little bladder, the urine escaping freer from the orifice of the urethra than it could get out from that of the prepuce. All this irritability and pain were removed by the operation.

Let me adduce another case where we are obliged to operate at once to get at a derangement which the phymosed prepuce conceals. I was sent for to a child of the farrier of Mr. Ferguson, the veterinary surgeon, who had had retention of urine for two days. I found the child in great pain and distress, the penis swollen and œdematous—the œdema causing the prepuce to be elongated to a great degree. I made a few punctures with a lancet into the swollen penis to lessen the swelling, but though the punctures caused a considerable exit of fluid, it was regenerated quickly again, and no effect produced. I then passed through the narrowed orifice of the prepuce a small gum elastic catheter with the stylet to try and get into the orifice of the urethra. I failed in this, but felt a sensation of grating, and on passing a probe I struck against a stone. It was likely, therefore, that a stone had become impacted at the end of the urethra. I slit up the prepuce and saw the end of a small stone sticking out of the urethra. With a forceps it could not be got out, the forceps constantly slipping from its polished oral end. With some difficulty I therefore passed a probe bent like a hook, and with some force I pulled out the stone. The urine immediately gushed out with great violence. The penis continued œdematous for a few days, but there was no further trouble in the case.

In cases of warts on the glans and round the corona and frœnum, covered by a prepuce which cannot be retracted, I have often operated. In these cases, through the orifice of the prepuce, the surface of some of the warts may be seen or felt like hard lumps through the prepuce. About two years ago a little boy was admitted into No. 5 ward, with phymosis and some yellow discharge and much irritation. I felt on the right side through the prepuce a hard mass, which, I thought, might be warts, though it was unusually hard. On slitting up the prepuce it turned out to be a thick flat piece of calcareous matter moulded on the side of the glans. You will find in Boyer some curious cases of very large masses of similar material in this situation.

In cases such as I have mentioned, where the prepuce is healthy, uninfamed, and non-adherent, the operation I perform is as follows:—I hold tightly, with a straight scissors-forceps, as much of the prepuce and its lining membrane as I wish to remove, taking care not to bring the skin of the penis too much forward or on the stretch, otherwise it retracts too much. I then cut off with a sharp straight bistoury the portion so seized. The integu-

ment runs back, while the lining membrane, not retractile, remains nearly stationary, as in Plate No. 1. I then slit

Fig. 1.

up with a scissors this inner membrane in the middle line, and as far as the edge of the retracted skin. The dotted line represents this incision. The next step is to fold over the lining membrane, which this slit allows to be readily done, so that its edge meets that of the skin, as shown in drawing No. 2. It is rarely necessary to put in any

Fig. 2.

suture as the lines meet so accurately; but should there be a gaping at any part a suture may be used. A little strip of lint spread with simple cerate is put round the penis at the cut line. The first part of this operation is like that recommended by Sir W. Ferguson; but the

second part, that of turning back the lining membrane to meet the cut edge of the skin, is a very material step, as it greatly expedites the healing. You have seen me operate in this way very often, and have witnessed the good results.

### NOTES ON ANOMALOUS ANATOMY.

By ALEXANDER MACALISTER, L.R.C.S.I., L.K.Q.C.P.I.,  
DEMONSTRATOR OF ANATOMY, ROYAL COLLEGE OF SURGEONS, IRELAND.

IN every department of Creation we find the prevailing principle to be unity in variety. The typical features of every class are modified differently in each of its component genera, and the characteristic marks of each genus are presented in varying modes of combination and arrangement in each species. The same general law we may even trace further in its operation, as it affects the individual organisms of every species; for, as there are scarcely two individual plants alike in shape, size, foliage, &c., in like manner there is a variation almost endless in extent to be found in the animal world. This is true most particularly among the higher and more complex groups of beings, as in these, from their intricacy of structure, there is much more scope for individuality of character than in the smaller and more simply constructed races, and thus structural variations are commoner among the vertebrates than among invertebrates, among mammals than among birds, reptiles, or fish, and in man than in any other mammal. In the human species, as no two individuals are alike in features, voice, or handwriting, so it is quite possible—nay, in the experience of anatomists, demonstrable—that no two are identical in anatomical arrangement, that here a muscle, there a nerve, and now an artery, will be found to vary from what is recognized as the type structure. In this, I think, we may find the clue to the many little discrepancies which are to be found in our standard works on anatomy, as mayhap the authors would correct their general notes by a few careful and painstaking dissections in which they might light upon modes of arrangement, perhaps not the most usual or typical. We will take one instance of this. In the accounts of the attachments of the pronator radii quadratus muscle, we find the usually accurate Harrison describing it as arising from the lower fifth of the ulna and extending to the lower fourth of the radius; while Cloquet, Cruveilhier, Jamin, and Marjolin, give its attachments as to the lower fourth of each bone. On the other hand, as far as my measurements have gone, the most usual and typical attachments seem to be those given by Ledwich to the lower fourth of the ulna and the lower fifth of the radius. As a general rule, we should regard as typical those characters which we find the most constant in the greatest number of individuals.

Anatomical variations in man occur more numerously in the vascular systems than in any other series of structures. Any one who has made injections of the lymphatics and veins knows how frequently they are to be found variable, or rather how comparatively seldom they are to be found similar or typical. As a rule, lymphatics are more irregular in arrangement than veins, veins than arteries. The muscular system in variation comes second to the vascular; and we may look upon the nervous as the least mutable of the three. Fascial variations are not of very common occurrence, but I hope soon to be able to publish several very interesting and surgically important cases of unusual arrangements of aponeurotic structures. In a paper laid before the Royal Irish Academy in the past session, I proposed a classification of muscular anomalies, based upon the admirable system of Mr. Wood, and I enumerated many varieties which had up to that time fallen under my notice. Since then new materials have been accumulating, and I have found many specimens of considerable interest to which I wish to direct attention.

Of muscles, which are not normally parts of the human frame, there are three which I will notice. The first

of these existed in a young female, and arose on the right side from the ilio-pectineal line immediately behind the attachment of Gimbernat's ligament, from this point it ran upwards and a little outwards, lying beneath the transversalis muscle, and upon the fascia transversalis, after crossing the deep epigastric artery, it terminated not far out from the median line, by being inserted into the fascia transversalis at a distance of two-thirds of the interval between the umbilicus and the pubis. To this fascicle the name Pubia-fascial might perhaps be affixed. Of the normal abdominal muscles on this subject I remarked a pyramidalis nearly reaching to the umbilicus, a supernumerary, supra-umbilical, linea transversa in the rectus, and a strong well-marked transversalis.

From the outer side of the origin of the extensor digitorum communis in the forearm of another subject, a small muscular band started and passed downwards, superficial and parallel to the tendon of the extensor secundi internadii pollicis, along with which it passed beneath the annular ligament in its third sheath, and was inserted in common with that muscle, the tendons coalescing opposite the base of the first phalanx of the thumb. A similar instance was noticed by Blandin, and the same arrangement exists in several mammals.

The palmaris accessorius muscle, many of whose mutations have been before noticed, occurred in a new form in both forearms of a strong well-developed male subject as a large expanded muscle, more than half the size of the flexor carpi ulnaris. It arose by two heads, one a tendinous, or rather fascial slip, from the point of the internal condyle of the humerus, superficial to the other flexor or pronator muscle. The second head arose fleshy and tendinous from the inner edge of the ulna under cover of the flexor carpi ulnaris, and extended nearly for the lower two-thirds of that bone. The two origins were separated by the ulnar nerve alone, as no ulnar artery existed in the subject. The insertions of the muscle were two-fold; first, by a tendon which was attached to the palmar fascia; and, secondly, by a much stronger band, likewise tendinous, which united with the abductor pollicis; as in one of the other cases quoted by me in the paper read before the Royal Irish Academy, this band was inserted into the outer side of the first phalanx of the thumb. In this subject the ordinary palmaris longus and brevis muscles were present and distinct. This accessory palmaris is, when existing, liable to many variations. Vicq-d'Azyr describes it as running from the coronoid process of the ulna to be inserted into the anterior annular ligament, and Rosenmüller has seen it coalescing with the flexor sublimis.

Of the duplication of normal muscles I have seen additional instances since I compiled my former list. One occurred in the case of the lesser pectoral, and was an extremely perfect example of this class of abnormalities, as the two strata were nearly equal in strength and development, and very closely corresponding in attachments.

The coraco-brachialis was the subject in the other instance, and here the additional portion sprang from the whole length of the inner or anterior aspect of the coracoid process under cover of, and extending posterior to, the insertion of the lesser pectoral. This muscle passed downwards, crossed over by the external cutaneous nerve, and lay first internal and then superficial to the normal coraco-brachialis; at the middle third of the arm it became tendinous, and lower down was connected closely to the natural coraco-brachial muscle, than which, however, it was inserted lower down by a round tendon, which lay internal and posterior to the brachial artery. This supernumerary part may perhaps be the homotype of that portion of the adductor magnus which detaches the round tendon, whose usual insertion is into the inner condyle of the femur.

Of the class of normal muscles with unusual origins there were some notable instances. One of these occurred in the case of the biceps. In the left arm of a subject there was—1st, a third or humeral origin for the muscle

springing from the bone external to the insertion of the coraco-brachialis, from which it was separated by the inner head of the brachialis anticus; 2ndly, a flat accessory tendon arose from the inner lip of the bicipital groove below the tendon of the latissimus dorsi, this after a short course joined the former or humeral head. In the right arm of this subject the first of these peculiarities existed, but the second was absent. A double coraco-brachialis co-existed with this anomaly.

In the left hand of a thin old male subject, the indicial tendon of the flexor digitorum sublimis became suddenly fleshy opposite the metacarpo-carpal articulation, and formed a belly two inches in length, which ended opposite the metacarpo-phalangeal joint in a rounded tendon, whose course and attachments exhibited nothing unusual. In this subject the lumbricales were quite normal and well developed. This variety seems to be a partial attempt at the digastric arrangement which I have more particularly described before, and which is to be found in Stenops.

One example of the splitting of normal muscles occurred in the instance of the flexor profundus digitorum, whose indicial portion was in a thin forearm perfectly differentiated from the remainder of the mass.

Of the other classes, as notable varieties have occurred to me since the formation of my list, but as an illustration of the frequently gregarious nature of abnormalities, I may mention that the last subject dissected by me showed the following peculiarities. The zygomatica minor was a slip of the orbicularis palpebrarum. The internal maxillary artery lay entirely behind the external pterygoid muscle. The two digastrics were united by the passage of the tendon across from one side to the other, the two anterior bellies being united and parallel, precisely the arrangement found in Macæus. A strong musculus risorius and a thin small zygomaticus major were present. The omo-hyoid had a large clavicular superadded to a suprascapular origin. There was an additional linea transversa in the rectus, and an enormously developed pyramidalis. The pubo-fascialis above described existed and was strongly marked. The posterior tibial artery was absent, and its place was supplied by the peronæal. The internal circumflex femoris was very large and came off from the obturator artery. The adductor magnus was split into two distinct parts, and the gluteus quartus of Meyer and Haughton (the ilio-capsular of Harrison) was of great strength. The psoas parvus was present and large. The rectus femoris had three heads; one from the anterior superior spine, one from the anterior inferior spine of ilium; and the third from the brim of the acetabulum. A peronæus quinque was present, and sesamoid cartilage in the tendons of the tibialis posticus and peronæus longus. An extensive junction was present between flexor longus pollicis and flexor digitorum longus, and the abductor ossis metatarsi minimi digiti of Huxley was very strong and separate. The infraspinatus secundus (Haughton et mini) was distinct and strong. The brachial artery divided opposite the upper border of the insertion of the coraco-brachialis into two branches of nearly equal size, one a dilated vas aberrans, somewhat similar to those described before, which terminated in the flexor sublimis muscle (DUBLIN MED. PRESS, vol. 11, p. 325); the other or trunk passed to opposite the coronoid process of the ulna, and there again divided into two branches, one the radial, which was very large and formed the whole of both the superficial and deep palmar arches, the other a short axis which gave off the anterior and posterior ulnar recurrents. The arteria articularis Meyer's and the anterior and posterior interosseous trunks. The triple attachment of the extensor primis interodii pollicis, described by Hood, was very distinctly marked, and a large coronoid head existed for the flexor carpi radialis separated from its condyloid head by the median nerve. A uniting band connected the extensores carpi radialis longior and brevior, and lastly, a few decussating fibres were present in the pronator radii teres. This last variety is of interest, as it was a step towards the X-

like state of the muscle mentioned by the American editors of "Meckel's Anatomy," or the double triangular state, described by Dr. Barton of the Philadelphia Hospital.

### INFLAMMATION FROM INSECT BITES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I think the following case worthy of record, owing to the unusually severe symptoms that followed such a trifling accident.—Yours, &c.,

CHARLES GARLAND, L.K.Q.C.P.I., L.R.C.S.I.

Newry, July 20, 1866.

Miss —, previously in good health, was bitten on the back of the hand by a species of fly at seven o'clock p.m., July 11th. During the remainder of the day and following night, the pain was very severe in the hand and along the arm to the shoulder; sleep absent.

12th: Erysipelatous blush all over hand, with considerable œdema extending to elbow, a feeling of coldness in limb, and general *malaise*.

The treatment consisted in confinement to bed, keeping arm stretched on a pillow, and using astringent and cooling lotions. Calomel and jalap in powder were also administered. Patient is now, July 28th, convalescent.

I have never seen nor heard of any case in which the symptoms ran so high as in the above, and I think it bears a strong analogy to similar cases occurring on the Continent. Had the patient, in this instance, been of bad constitution, a fatal termination from pyæmia, &c., would most likely have been the result.

### NOTES ON SOME CASES OF ECZEMA.

By J. S. A. CUNINGHAM, L.K.Q.C.P.I., L.R.C.S.I., &c.

#### II

(Continued from Vol. i., page 536.)

THE subject of causation has long been one of the most obscure departments comprised in the natural history of diseases—why one person, to all external appearances under the same hygienic influences, and surrounded by similar vital conditions, should escape the noxious *entity*—call it what we will, the product of "zymotic, cachectic, monorganic, metamorphic, or thanatic" influence—which lays his fellow on the bed of suffering, and may even extinguish the flickering lamp of life; while the other, more fortunate, pursues his accustomed avocations unscathed by the blasting breath of the fell-destroyer, and untrammelled with the thongs of debilitating disease, is truly, in the majority of instances, wholly inexplicable by any means hitherto made known to us by the inventive genius and far-seeing wisdom of our noble profession; in truth, if, perhaps, we except the action of most of the known active poisons as the efficient cause capable of producing a special action on the living economy, whereby the necessary changes indispensable to the continuance of vital activity are impeded or wholly suspended, thus producing tangible and easily recognized forms of disease, or the climax of all diseased processes—death; the etiology of disease is, even at the present day, very obscure, and in many cases entirely unknown to us. How long we may be destined merely to seek for, and by the aids of our ever-advancing art, endeavour to estimate the importance of the many varied, predisposing, and exciting causes which seem capable of favouring the production of diseases, without having arrived at the cause or causes whereby the subtle primordial change is produced, necessitating the development of a consequent deviation from that state most conducive to the healthy condition of the living organism, depends, I think, in a great measure on the scanty, and, in many cases, meagre records, we possess of most diseases. If, then, we would endeavour to throw the light of experience in no dim or fitful ray into the dark recesses of the production and early history of disease—thus indicating the

first step to its prevention and treatment, we should not shun the midnight lamp or the toilsome exertion of an over-wrought day, nor yet the chilling breath of criticism, but sustained by the *mens sibi conscia recti* endeavour by reasoning upon accurately observed facts to arrive at true and legitimate deductions, alike untrammelled by theory and unbiassed by personal considerations. It has been well observed "that the value of medical science depends wholly upon its connexion with medical art."\* It might, to be sure, be cultivated as an interesting subject of inquiry independent of this connection, but it derives most of its interest, and all of its importance and practical utility, from its agency in the prevention, mitigation, and removal of disease. These are its great ends and objects, and so far only as it attains them or ministers to them, can it lay claim to our veneration and regard as a blessing and a benefit to our race. It happens, however, that less confidence is felt in medicine as an art than as a science. It is precisely here in its chief end and purpose that it is said to fail. Physicians, it is admitted, may indeed understand the seat and nature of disease, but it is denied that they can, with any certainty or uniformity, control or cure it. Practical medicine, it is asserted, is altogether a haphazard affair of guess and conjecture, "doing good when this happens more by accident than according to any constant and fixed principles, and as often doing harm as good."

It shall be my endeavour to show that even in the case of eczema, belonging, as it does, to that class of affections termed skin diseases, so proverbially refractory under almost every method of treatment, is, when rightly understood, in most cases as easy of cure as intermittents by quinine, or chlorosis by ferruginous preparations.

That eczema is generally the result of irritation of some sort has been long recognized, and when the history of almost all the cases met with in practice comes to be inquired into, it will be found, in the great majority of instances, that the patient attributes the affection of the skin as an effect following on some form of irritation as its cause; thus it is often induced by irritating lotions and ointments. This is well exemplified in the following case which came under my notice a short time since. The patient, a healthy-looking and robust countryman, by occupation a blacksmith, aged about 40 years, was attacked with the affection on the back of the hands, wrists, and subsequently the greater part of the upper extremity became implicated in patches with the cutaneous eruption; there was much constitutional disturbance, with pain in the head and obstinate constipation of the bowels, pain in and enlargement of the lymphatic glands in the axillæ. The man, however, still continued to work, and shortly after the commencement of the eruption he applied at the dispensary in the neighbourhood and obtained an ointment which was to be rubbed on the affected patches night and morning, with an aperient draught *statim sumendus*. The application of the ointment caused intolerable itching, accompanied with a smarting sensation on and around the diseased parts. He still, however, applied it for two or three days more, but had at length to desist, the itching becoming intolerable, so that he could, with difficulty, refrain from "tearing off the skin," as he stated, when I saw him a few days after. Some of this ointment which he had preserved I found to contain a large amount of *tartar emetic*, so much, indeed, that if we may form any conclusion from the quantity contained in the half-drachm (nearly) which I obtained, the total in an ounce box-full must have reached no inconsiderable amount; indeed, the effects it produced—if we may believe the great irritation to have been caused by its action—were abundantly visible in the appearance of the erupti<sup>n</sup>, especially at the bend of the elbow of the right arm, where the vesicles had entirely disappeared, with the exception of a thin circle around the patch, which presented a heterogeneous mass of scabs and scales intersected with livid excoriations, and deeply cracked in the line of the articulation, exuding a bloody sanies, and bleeding when scratched, which the

patient could with difficulty refrain from doing momentarily; the other patches on the extremity were good examples of the form of the affection termed *eczema rubrum*, and presented an inflamed basis, with here and there small yellowish red crusts which must have been formed very rapidly, as the result of scratching caused *pro tem* their entire desquamation; but in a few hours the patches would again be found covered with scales as before, provided the patient did not disturb them by scratching, with the exception of a few patches presenting the true eczematous vesicular and scaly eruption (not confluent) on the chest and lumbar region of the back. The affection was confined to the upper extremities only, worse on the right than the left. The bowels being constipated, the treatment was commenced by ordering the following:—

℞ Olei ricini, ℥i.

Tincturæ sennæ, ℥ii.

Aquæ menthæ pip., ℥ss. M.

Fiat haustus statim sumendus.

And (having long since experienced the good effect of the following liniment in cases attended with itching of the skin, no matter from what cause produced, I determined to try it in this case; and I may add my expectations were not disappointed, as the *next day* the itching, which was so marked a feature, had almost entirely subsided, notwithstanding the continuance of heat and slight inflammation).

℞ Acidi hydrocyan. dil., ℥ss.

Bicarb. potassæ, ℥i.

Aquæ rosarum, ℥iv. Solve.

Fiat liniment. partibus affectis ter quaterve in die infricetur, et signetur, "Poison."

The next day the above draught not having produced the required effect, two drops of croton-oil were administered, which caused copious watery discharges, with great amelioration of the heat of skin and subsidence of the headache. On the following morning the more active treatment of the case was commenced by ordering the following:—

℞ Liq. arsen., m̄ij.

Infusi dulcamaræ, ℥viii. M.

Fiat mistura ejus unciam ter in dies post cibum capiat.\*

For a few days after the commencement of the arsenical treatment no decided improvement was visible in the eruption, if we except a cessation of the formation of any new crusts by the bursting of the vesicles; this may, however, have been caused by the patient not scratching the part, as the itching had then totally ceased to annoy him. A week after the first administration of the mixture the amount of liquor arsenicalis was increased to *forty minims* in the eight ounces, and two days after this to *six minims* in the ounce, to be taken thrice daily (*i.e.*, forty-eight minims of the liquor arsenicalis to eight ounces of the infusion of dulcamara). This latter was continued throughout the remainder of the treatment, and, with the exception of an occasional purgative when required, was the only medicine used. Under this treatment the patient steadily improved, and in just two months from the commencement of the treatment with arsenic the entire disease had disappeared, without one bad symptom having arisen during that time, although the patient had consumed a considerable quantity of the drug. If we allow sixty days as the entire time from the first administration of the arsenical solution to the period of perfect cure, we may thus tabulate the amount received into the system:—

\* To insure the requisite amount of the remedy being taken, and prevent accidents where medicines of a dangerous nature are prescribed to patients not under immediate and continuous observation, I am in the habit of ordering a one ounce phial (as in this case, or any other size that may be requisite) to be attached by a string to the bottle containing the medicine, and instructing the patient to measure out the small bottle-full at each period directed for taking the medicine, which has the advantage of obviating all chance of accident, and, in addition, we are able to convey to the most obtuse intelligence a clear conception of the amount to be taken at each time.

\* Bartlett on "Certainty in Medicine." Philadelphia, 1848.

|                                                                                                                                                              | Period. | Strength of mixture.      | Quantity taken. |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|---------------------------|-----------------|
|                                                                                                                                                              | 7 days  | m <sup>30</sup> to ℥viii. | ℥i. ter die.    |
| Liq. arsenicali                                                                                                                                              | 2 "     | m <sup>40</sup> "         | " "             |
| (grs. iv. As O <sub>3</sub> to ℥i)                                                                                                                           | 51 "    | m <sup>48</sup> "         | " "             |
|                                                                                                                                                              | Total.  |                           |                 |
| $\left. \begin{array}{l} m78\frac{1}{2} \\ m80 \\ m918 \end{array} \right\} = m1026\frac{1}{2} = \text{grs. } 8\frac{3}{4} \text{ As O}_3 \text{ (nearly).}$ |         |                           |                 |

In cases where arsenic is given for any length of time we are taught that "saturation" of the system by the metal may take place, it thus acting as a slow poison, and producing results in a chronic form, similar to those observed when administered in poisonous doses; but that the amount required to act thus must vary within wide limits has been frequently proved, and I think amongst ordinary cases observed in practice, if we take the precaution of administering an active purgative every alternate week, the chances of arsenical poisoning, even where the doses amounts to eight minims three times a day, will be reduced to a minimum. Another objection to the employment of arsenic in cases of eczema and skin diseases generally is its uncertain action—cases apparently getting quite well and in a few weeks or months breaking out as bad as ever, if not worse; not denying that such may occur without any obvious specific cause, still I think the returns of the disease is exactly similar to what takes place in all other affections (some "zymotics" excepted), which may be relieved, or cured if you will, at the time, but on a return of the patient to his accustomed occupation, or a recurrence of the primary cause which produced the disease in the first instance, should we be surprised to find the affection returned in all its pristine virility? or blame the non-continuous action of the remedies first used? If, then, we believe eczema to be caused by irritation internally, externally, or however produced, why, it may be asked, should it differ from other diseases which recur on a continuance or reapplication of the first exciting cause? (e.g., necrosis of inferior maxilla from exposure to fumes of phosphorus, black rot from inhalation of carbonaceous particles, colica pictonum from absorption of lead, &c.) Almost all diseases may be cured, indeed for a time, but let the patient be exposed afresh to the action of the deleterious substance—let the irritation be renewed, and the silent germs again put forth their noxious powers, and stimulated into new life cause the very same train of symptoms which at first characterized the disease. It is not otherwise with affections of the skin. We should not therefore blame the non-efficient action of the remedy employed, but seek to learn the hidden and often obscure latent cause which, having first given birth to the disease, may, by the action of medicine, be for a time suppressed, only on a future occasion to burst forth with renewed energy on a recurrence of the original producing cause.

(To be continued.)

#### PROF. A. C. POST'S NEEDLE DIRECTOR.

This instrument is designed to facilitate the introduction of insect pins for sutures in wounds of the face, and of other parts where it is important to secure an accurate adaptation of the edges of the wound.

It consists of a needle two inches and a quarter in length, of a diameter corresponding with that of a very large darning-needle, straight except at the point, where it is slightly curved to the extent of a quarter of an inch, and having a small flat handle at its proximal extremity. The curved portion of the needle is flattened, and has cutting edges. Throughout the greater part of its length the needle has a groove on the side corresponding with the convexity of its curve. In using the instrument, the needle is passed through the edges of the wound in the position which is to be occupied by the pin, and the pin is then slipped along the groove upon its under surface. By this means the most slender and delicate pin may be passed through the skin with perfect facility, and without being bent out of shape. As soon as the pin is introduced, the needle is withdrawn, and the pin is secured by a thread in the form of the figure. And the point of the pin is removed by cutting-pliers.

## Hospital Reports.

### MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

#### CASES UNDER THE CARE OF MR. PORTER,

SENIOR SURGEON TO THE HOSPITAL.

[Reported by ARTHUR WYNNE FOOT, M.D.]

(Continued from page 69.)

#### ANEURISM OF THE AXILLARY ARTERY.

Case 33.—During the present month a man, 67 years of age, was admitted into the Meath Hospital, under the care of Mr. Porter, having a pulsating tumour connected with the left axillary artery. He had been suffering for the last three weeks from severe pain felt along the inside of the left arm, and in the neighbourhood of the left elbow joint. The day before his admission he discovered a "lump beating" below his collar bone. On examination a tumour was found, about the size of a large walnut, with strong eccentric pulsations, occupying the first stage of the left axillary artery. A loud bruit de soufflet is audible in the tumour with the stethoscope, and its pulsations can be entirely arrested by pressure applied to the terminal stage of the subclavian artery, as it passes over the first rib. Mr. Porter remarked upon the interesting fact that this patient had last year been the subject of an aneurism of the right popliteal artery, which had been successfully treated by digital compression applied to the main vessel. The consolidation of the aneurism was accomplished in thirty-six hours and forty-five minutes. The patient's age, his previous history, and the condition of the coats of the superficial arteries make it probable that he is an example of the condition termed the aneurismal diathesis, from the facility with which dilatations of the arterial tunics become formed.

The constitutional tendency to the formation of aneurism is sometimes extreme, as in the case under the care of Pelletan, senior surgeon to the Hôtel Dieu, in which sixty-three aneurisms were found in the same body.

Having pointed out the various points of the diagnosis of external or surgical aneurism which this case well exemplified, Mr. Porter stated his intention of employing digital compression of the vessel leading to the tumour, as a means of cure; should this treatment not effect the consolidation of the aneurism, he will apply a ligature to the subclavian artery.

#### LARGE EPULIS ORIGINATING IN THE TOOTH SOCKET.

Case 34.—A female, 30 years of age, was admitted during the present month, under the care of Mr. Porter, with a large growth springing from the molar region of the right side of the lower jaw, disfiguring her appearance by the protrusion of her cheek, and interfering with mastication and articulation. About two years previously, the first molar tooth at the right side of the lower jaw became so loose that she pulled it out herself. Shortly afterwards a small cherry-like tumour was observed growing from the socket, this tumour became gradually larger until it attained its present size, that of a small hen-egg. It overlaps and conceals the adjacent teeth, investing both the lingual and buccal surfaces of that portion of the lower jaw, and encroaching upon the tongue and cavity of the mouth. The superior part of the tumour has become ulcerated from frequent pressure against the opposing teeth of the upper jaw, and the injured part is the seat of pain which is not severe, and has but lately occurred. The tumour possesses the same degree of firmness and vascularity as the healthy gum, and there is no glandular enlargement. Mr. Porter drew attention to the distinction between these kind of tumours and malignant growths in the same situation, and to the resemblances which an epulis in a

state ulceration, the seat of hæmorrhage and of suppuration, presents to malignant disease, remarking upon the origin of the disease in this case from the alveolus as being less common than that from the inter-dental gum, as in the case operated on by him in May. The woman's health being delicate, her confinement having taken place three weeks ago, any operation for the removal of the tumour has been postponed until she is stronger, as it will be necessary, on account of the size and situation of the disease, that the cheek should be partially slit from the angle of the mouth to give room for the extirpation of the growth.

## RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

### DR. LYONS'S CLINIQUE.

#### MISCELLANEOUS NOTES.

*Typhoid Fever.*—When carefully noted the clinique of the practical physician in hospital, as well as in private experience, will be found to present cases of true *typhoid* or enteric fever more commonly than is often supposed. Error or oversight in diagnosis may occur in either of two ways. In the one case, a patient, with fully marked symptoms of *typhic* prostration, *facies typhosa*, sordes on teeth and lips, and general hebetude, may be at first assumed to labour under ordinary typhus, and may be treated accordingly, no suspicions being awakened until later in the disease. The presence of diarrhœa, and it may be of melæna or grave symptoms of enteric or peritoneal complications, with long deferred convalescence, or it may be fatal issue at some interval between the thirtieth and sixtieth day makes known the true nature of this insidious malady. To those who believe with Dr. Lyons in the absolute necessity of much careful discrimination between typhus and typhoid fever, especially in regard to the all-important questions of special alimentation and medication, the importance of early diagnosis cannot be over-estimated. In the more insidious non-typhic forms of typhoid or enteric fever, the disease is not infrequently overlooked, and the patient is supposed to suffer from an attack of ordinary simple continued fever, unsuitable remedies or incautious regimen are employed, and the patient succumbs to the failure of art, not the gravity of disease.

The following case exhibits well marked the principal features of the first variety of enteric fever alluded to:—

J. McV., aged 19, a seaman, was admitted to the Hardwicke Hospital on the 20th June, 1866. He had suffered from "pains in the guts," as he expressed it, so early as the 4th June, but does not appear to have had rigors till a week later. He was much exposed at sea during part of this interval, and appears to have taken purgatives. On admission he was extremely low and prostrate, with much typhic depression, *facies typhosa*, and foul tongue, with sordes on teeth and lips. On the previous night the bowels had been acted on seven times, and there was much intestinal irritation, with ilio-cœcal gurgling. On close inspection four or five lenticular rose-coloured spots could be discovered on the abdomen, much obscured by the general dusky hue of the surface. The pulse was exceedingly weak, but not above 100 per minute.

In consideration of the state of typhic depression which he presented, this patient was placed on chlorate of quinine, in three-grain doses, with six ounces of wine; mild astringents were employed to check the diarrhœa; the abdomen was assiduously poulticed, and a rigid adherence to the use of milk and farinaceous diet was enforced throughout. Under this treatment he soon evinced manifest symptoms of amendment. The pulse fell to 88; the diarrhœa was speedily controlled; ilio-cœcal gurgling and tenderness on pressure in the abdomen disappeared; the typhic aspect gave place to a more sthenic condition, and convalescence began to be steadily established after the thirtieth day. Perseverance in the restricted milk and farinaceous diet

was enjoined until the fortieth day, when beef-tea with bread was found to be well borne, and in a few days subsequently the patient left hospital, a marked instance of the safe conduct of a case very unpromising at the outset through a protracted and treacherous malady.

Dr. Lyons regards this case as well exemplifying—

(a.) The combination of the state of *typhic* depression, with the specific intestinal lesion.

(b.) The value of regimen as an adjunct to medication in the management of the enteric lesion.

*Hay Fever—Hay Asthma.*—The rich and abundant meadow harvest of the present season has given rise to some well-marked cases of this singular pyrexial malady, associated as it usually is with more or less bronchial and, in some instances, general mucous irritation, and much nervous irritability and depression. Dr. Lyons records an instance of a family of nine persons being simultaneously affected by this disease. The affection is variously known as hay-fever, hay-asthma, heu fieber, frùhsommer-catarrh of the Germans. The odorous emanations of various grasses, of the rose under certain circumstances, and of ipecacuanha, are known as active agents in the production of a form of bronchial irritation, accompanied by a varying amount of pyrexial action in different individuals, and recurrent in the same persons under similar circumstances of season and exposure. To a like cause must be assigned instances of obscure and peculiarly irritable bronchitis, which are found to be rebellious to all treatment during the season of hay-making, and are only to be cured by total removal from the vicinity of meadows in the season of hay harvesting.

The disease is marked by the occurrence of constriction of the chest, cough, mucous râle, with more or less copious yellow expectoration, nervous excitability, and occasionally with smart fever, accompanied by subsequent depression, sleeplessness, wandering, or actual delirium. Expectorants, tonics, the citrate of quinine and iron, and more recently sulphur fumigations, have been recommended for the treatment of this affection. In some cases active measures of support and stimulation are required, and the tendency to asthenia has been occasionally, in Dr. Lyons' experience, such as to warrant grave alarm for the safety of the patient, and to call for a very bold use of stimulants.

## ADELAIDE HOSPITAL.

### CASE OF STRANGULATED FEMORAL HERNIA.

Under Mr. BARTON'S care.

[Reported by SIDNEY R. SMYTHE, Esq.]

ANNE A—, a native of Germany, 48 years of age, had a femoral hernia for twenty-six years, which she kept up with a truss. Upon the morning of Monday, 28th May, when getting up, she experienced great pain in the tumour, and had an inclination to be sick. She went to bed and used stupes, &c., but with only partial relief. Her symptoms becoming worse, Dr. Hayden of Harcourt-street, was at length summoned upon Thursday, the 31st, when, finding the hernia strangulated, and having in vain endeavoured to reduce it, he advised her removal to hospital. She wished to be taken to the Adelaide, so she was at once conveyed thither. Mr. Barton saw her at half-past seven o'clock in the evening, and upon examination found a strangulated femoral hernia on the right side, about the size of a small orange, tense, but not very painful. Vomiting frequent; pulse rapid and small. Considering that the hernia had been strangulated more than three days, Mr. Barton determined to operate at once, if the warm bath which was being got ready failed to relieve the symptoms. At ten o'clock, assisted by Mr. Morgan, Mr. Barton operated. The sac was opened, as it appeared too hazardous to omit an inspection of the contents. After about eighty-four hours' strangulation there was scarcely a drop of fluid in the sac; the contents were omentum, and a small knuckle of intestine, which was of a very dark purple

colour, but bright; the stricture was peculiarly hard, and required three or four cautious applications of the hernia knife before sufficient room was obtained for the reduction of the intestine, and when this was accomplished the omentum quickly followed. Two points of suture held the lips of the wound well together, the thigh was supported by pillows in the bent position, and a full opiate was then given, the patient having been under the influence of chloroform during the operation.

June 1st: Patient had slept several hours; tongue dry; pulse 88; abdomen full and tender on pressure. Eight leeches over tender part, afterwards a large poultice. Calomel gr. ii. and opium half a grain, to be taken immediately, and again at night.

2nd: Decided tenderness in right iliac region; pulse small and rapid; respiration very rapid. Calomel and opium given every four hours.

Upon the 4th the mouth was slightly touched, and the symptoms relieved, and the patient went on safely, her recovery being slightly retarded by the formation of mucus abscess in the wound; after this was opened the wound healed kindly, and a proper truss was applied.

## Foreign Medical Literature.

### CASE OF EPITHELIAL CANCER OF THE ŒSOPHAGUS, WITH PERFORATION OF THE AORTA.

Communicated by Dr. C. van WICHEREN.

Translated from the *Nederlandsch Archief voor Genees- en Natuurkunde*, Eerste Jaargang, Utrecht, 1865, p. 508.

By WM. DANIEL MOORE, M.D. Dub. et Cantab., M.B.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

THIS case is that of a patient whom I saw only a few hours before his death, when he was brought into the Royal Hospital. He had been long under the care of heer Lulofs, officer of health, and, through the kindness of my esteemed colleague, I am enabled to communicate the following, to which I shall have to add only in the main the results of the post-mortem examination:—

J. B., a subaltern officer in the battalion of Sappers and Miners, aged 49, was formerly addicted to the abuse of spirituous drinks, which he gave up only in the beginning of his illness. This dates from May, 1863, when he began to complain of pain in the region of the stomach, closely resembling gastralgia, and which was treated with narcotics and antacids. At first some improvement seemed to be obtained, but this was of short duration. About January, 1864, difficulty in swallowing solids supervened: the patient felt as if the morsel stuck for a while about half way down the œsophagus, and afterwards descended slowly to the stomach. At the same time there was occasional vomiting shortly after swallowing. The pain, which was always felt most in the epigastrium, a little to the left side, increased in proportion as deglutition became more difficult, and increased also with the vomiting.

The patient had long avoided the use of all stimulating food and drink, and now restricted himself, moreover, to taking food in a soft or fluid form, but as nourishing as possible, and also in sufficient quantity. As medicines he made use of oily and narcotic remedies, when the pain or vomiting was particularly severe, and these then produced for him some alleviation of his sufferings. The vomited matters, which consisted of the food he had eaten, mixed with much mucus, had so far never been bloody.

Notwithstanding that the difficulty of swallowing, pain and vomiting increased, the patient's general state continued very satisfactory, inasmuch as there was scarcely

any perceptible loss of power or emaciation; he could even daily attend to business. His appetite also long continued acute, although his tongue was now covered with a persistent greyish coating, and his breath was most disagreeable.

His condition now remained for a long time apparently unchanged, until on the 28th of August, after a movement of deglutition, he suddenly felt a most violent tearing pain along the course of the œsophagus, which was so severe that at first he dared not venture on the slightest effort at swallowing. Upon this, feverish reaction ensued, and the patient suffered for some days, partly in consequence of nearly total abstinence from food, from a feeling of weakness.

This particularly violent pain did not return, not even when the patient after a few days again ventured to use some fluid sustenance, which, contrary to expectation, was swallowed with much greater ease than before. The vomiting was also less frequent; the vomited matters now consisted, besides the remains of food, often of a mucopurulent, sometimes rusty-coloured fluid.

On the whole, therefore, the patient had for some time considerable alleviation. It is true the pain never entirely disappeared, but it lasted a much shorter time, and was, because the difficulty in swallowing was much less, less violent; he had a feeling as if the obstruction was in great part removed. He could, therefore, again use a sufficient quantity of food, of course only in the fluid form, so that his strength was once more restored, and the emaciation was not striking. His skin was indeed pale, but had no cachectic appearance.

This favourable change was, however, not of long continuance. At the end of September swallowing was again as difficult and painful as before, and the vomiting returned in a much greater degree. The use of food also became progressively more difficult, so that the patient's suffering now, for the first time, reached its highest stage. In the beginning of October the vomited matters were almost always tinged with blood. At last, on the evening of the 14th of that month, more than six ounces of blood was discharged in vomiting, with symptoms of great distress, which lasted all night. It was not, however, until the following morning that the patient called in medical aid, when another vomiting of blood ensued, and his state became very critical. He was then, at about ten o'clock in the morning of the 15th October, brought to the Royal Hospital, where we found him with distinct symptoms of internal hæmorrhage. His face was deadly pale, and had an anxious expression; his eyes were sunken; the lips and tongue were blanched; the extremities were cold, covered with a clammy sweat, and quivering; the pulse was extremely small; the patient was on the verge of complete syncope.

At about half-past eleven he again threw up, with great distress, and with violent straining, about fourteen ounces of arterial blood. The state of collapse now rapidly increased until about one o'clock p.m., when a tendency to vomit again manifested itself, with great distress, under which the patient sank, without the vomiting taking place.

*Post-mortem examination.*—The body was in good condition; there was distention of the epigastric region, with resistance on pressure, and a dull sound on percussion.

*Abdomen.*—The stomach was highly distended, and translucently red. After tying the duodenum, the stomach was opened along its great curvature, whereupon a large quantity of coagulated blood was discharged. The mucous membrane was everywhere normal, without ulceration or erosion. The rest of the abdominal organs presented no abnormality. When the intestines were removed the inferior cava and the aorta were seen on a level with the third and fourth lumbar vertebræ, diverted from their ordinary direction, and making a curve upwards. The cause of this was found to be a circumscribed tumour, of the size of a small hen-egg, situated between the vertebral column and the vessels, raising the latter, and being very firmly connected with both parts. The vessels themselves exhibited no morbid change. The lumbar portion

of the vertebral column, with the tumour connected with it, and the vena cava inferior with the aorta, were now removed, and set aside for further examination.

*Thorax.*—The lungs were sound; at the posterior part were tolerably firm adhesions between the pleura pulmonalis and costalis; the left lung was tolerably firmly connected with the middle portion of the œsophagus. The heart was free from valvular or other lesions. It was now removed along with the aorta, trachea, œsophagus, and stomach, which was accomplished not without difficulty, in consequence of the existence of very firm adhesions between the œsophagus and the vertebral column. These parts were also firmly connected to one another by very dense connective tissue.

On external examination, the œsophagus, just above the cardia, was seen to be considerably thickened, and throughout its entire inferior half it was very firm to the touch. Its calibre was so constricted that the finger could not be introduced from the cardia. The lymphatic glands around the œsophagus and the bifurcation of the trachea were enlarged, very firm to the touch, and were of a bluish black colour, from deposition of pigment.

After the heart was removed, and the aorta and œsophagus were laid open in the longitudinal direction, only the upper part of the œsophagus appeared to be still healthy.

From the level of the third dorsal vertebra to near (2½ centimètres, or '984" above) the cardia, the mucous membrane was almost everywhere destroyed, or was so loosely connected with the subjacent layers, that it was easily removable with the forceps. Here and there small coagula of blood were present between the remnants of the destroyed tissue. Where the degeneration began superiorly the calibre was very much constricted, as well as at the inferior part above the cardia. Between these constricted parts the canal was dilated posteriorly in the place where the œsophagus bends over the aorta. Here, in particular, not only the mucous membrane, but throughout a certain extent, the whole œsophageal wall, was destroyed. Opposite this place we now observed in the anterior part of the wall of the aorta a small opening, about a fourth of a centimètre in extent, partly covered by a thin membrane.

This opening communicated with the cavity of the œsophagus, by means of a canal, about a centimètre in length, directed obliquely downwards, which had formed in the connective tissue existing between the two parts. In the seat of the communication of the aorta with the œsophagus, the middle and outer arterial coats, as well as the whole œsophageal wall, were destroyed for about a centimètre around the opening. The inner coat was not affected, but appeared to be torn by the pressure of the blood flowing through, as the membrane which hung loosely over the opening was a continuation of the inner coat, and could be laid in such a manner over it as to leave only a small slit. The inner surface of the aorta exhibited in addition some flat, not white (atheromatous) spots.

On microscopic examination it appeared that the destruction just described was the result of cancerous formation, and precisely of epithelial cancer. The large cells, resembling scaly epithelium, were present in such preponderating number that we could perceive among them only a few other cells of irregular formation, with free nuclei. In many cells the nucleus was swollen out into a large cyst; here and there they were packed together in small heaps, or were arranged more or less concentrically.

Among the cells were seen a few streaks of connective tissue as remnants of the decayed tissue, and near the seat of perforation of the aorta were many corrugated elastic fibres, derived especially from the outer coat. Everywhere, both directly beneath the mucous membrane, and in the muscular coat and the surrounding connective tissue, between the aorta and the œsophagus, the same degeneration was met with. The enlarged lymphatic glands behind the œsophagus exhibited similar degeneration.

From the results of this investigation it was, *a priori*, probable, that the tumour in the lumbar region was also

formed by a similar production of morbid growth, and microscopical examination confirmed this suspicion. It consisted likewise exclusively of epithelial cancer, in the form of a circumscribed tumour, surrounded with an envelope of connective tissue, which had developed itself from the membrane attaching the great vessels to the vertebral column. Thin streaks of connective tissue ran as a wide-meshed stroma through the tumour, and between these the large, flat, rhomboidal cells were very beautifully seen.

In the part of the vertebral column, extending from the sixth thoracic to the third lumbar vertebra, no cancerous formation was to be traced in the connective tissue. There was consequently no extension of the process by continuity, but the cancerous tumour in the lumbar region was anatomically independent.

In the foregoing case the phenomena observed during life accorded with those discovered upon post-mortem examination. The formation, without any definite cause, of an organic constriction of the œsophagus in a man of a rather advanced time of life, who had formerly been addicted to the abuse of strong drink, would necessarily give rise to the suspicion that a cancerous degeneration lay at the bottom of the case, even if the symptoms of emaciation, loss of strength and colour, which usually accompany a chronic cancerous affection, were wanting.

While the dilatation of the œsophagus in the particular situation was gradually induced by ulceration of the cancer, it is very probable that the total destruction and perforation of the mucous membrane had taken place, when the patient on the 28th of August suddenly felt a violent rending pain in this part, whereupon for some time a remission in the symptoms ensued. Probably, too, the other coats were then soon after destroyed. Effusion of food into the mediastinum could not, however, take place, on account of the intimate union with the surrounding parts effected by means of condensed connective tissue. That the temporary improvement was not of long duration cannot be matter of surprise, as the cancerous formation could now freely progress in the connective tissue binding the œsophagus to the aorta, and could thus soon reach the arterial wall, whose destruction is a result of the same process.

Between the first vomiting of blood and death a comparatively long time elapsed, nearly twenty-four hours. As the perforation of the aorta took place, by laceration of the inner coat, the opening was at first only small and could consequently give exit to but little blood, which could now spread in the connective tissue between the œsophagus and the aorta, coagulate there, and so prevent for a short time any further effusion. These circumstances could, however, ward off the fatal hæmorrhage only for a short period. When for the third time a violent effort at vomiting occurred, all these obstacles were overcome, and the blood flowed freely through the œsophagus into the stomach, whereupon almost immediately death ensued.

From an anatomico-pathological point of view this case is not devoid of interest.

If the patients have passed the period of constriction of the œsophagus by not yet softened cancer, they almost always succumb in consequence of anæmic marasmus, before the process has accomplished greater destruction. More rarely does perforation of neighbouring parts produce communication with the cavity of the œsophagus. Of perforation of the trachea, of communication of the latter or of the lung with the œsophagus, different cases have been cited by earlier and later writers, among others by Lieutaud,\* van Doeveren,† Albers,‡ Vigla,§ Hartung,||

\* *Historia anatomico-medica*. Paris, 1767. Tom. ii., pars. iii. P. 310.

† *Observationes pathologico-anatomicæ*. Lugd. Batav. 1789. Obs. ii.

‡ *Erläuterungen zu dem Atlas der pathologischen Anatomie*. 2. Abtheilung, p. 219.

§ *Archives générales*, xii. 1846.

|| *Hufeland's Journal der praktischen Arzneikunde und Wundarzneikunst*, 1838. Bd. 86. St. G.

and others. There are also numerous examples of perforation of the aorta with effusion of blood into the œsophagus, but then in general the case was one of aneurism of the descending aorta, which burst after it had perforated the œsophagus. But perforation of the aorta, in consequence of cancerous ulceration, primarily proceeding from the œsophagus, is extremely rare. Only three cases of this kind do I find on record: one by van Doeveren,\* one by Bürger,† and the third by Pfeufer.‡ Bürger, in his case, distinctly mentions scirrhus degeneration and ulceration of the coats of the œsophagus as the cause. In like manner, carcinoma œsophagi is mentioned by Pfeufer; in this case there existed, moreover, communication with the trachea. Van Doeveren, however, does not speak of cancer, but attributes the ulceration he met with to inflammation. But perforating ulcers in the œsophagus occur only in consequence of the action of accidentally swallowed caustic substances or of sharp foreign bodies.

Also the simple perforating ulcer of the œsophagus, which Albers looked upon as the analogue of the *ulcus perforans ventriculi*, is referred by Förster and most recent investigators to the class of cancerous degenerations. We may, therefore, consider the observation of van Doeveren as a case of the same nature. According to the accurate description of the post-mortem examination, and the drawing which Sandifort§ gives of this case, it presents the greatest analogy to that observed by me.

As to the form of cancer, Förster, too, found the epithelial form thirteen times in sixteen cases of cancer of the œsophagus. Connected herewith is the rarity of secondary cancerous tumours in this disease.

### Abstracts of the Scientific Societies.

ROYAL SOCIETY OF LITERATURE.—July 4.—Sir C. Nicholson, Bart., in the chair.—Messrs. F. H. Petrie and E. Villin were elected members.—Mr. Vaux read a paper "On a Greek Inscription from Thessalonica," which had been procured by the Rev. D. Morton, through the kindness of R. Wilkinson, Esq., H.M. Consul, Salonica. This inscription is of much interest, as confirming the statement of St. Luke in the 17th chapter of the Acts of the Apostles, that Thessalonica was governed by officers, called *Politarchs*; a title, curiously enough, found in no work of classical times. Mr. Vaux traced the history of this inscription from its first publication by Muratori, in 1740, through the successive works of Pococke, Beaujour, E. D. Clarke, Leake, Swan, Cousinery, Boeckh, &c., and showed that, though some of the later copyists had recorded the inscription with tolerable fidelity, none of them had produced a rendering of it so perfect as that shown in the photograph sent to Mr. Morton by Mr. Wilkinson.—Sir Patrick Colquhoun read a paper "On the Nature and Origin of Romaic Greek," in which he pointed out that this dialect is, properly, the language of the lowest trading classes, and may be considered as a sort of Greek *Lingua franca*. It can hardly be held deserving the name of a language, nor would really be deemed to be so by any except the so-called "Modern Greeks." It has little or no connexion with the artificial language which has been invented by newspaper-writers, authors and the bar, and is wholly useless as the exponent of the ideas of any persons except the poorest and humblest classes.

ARCHÆOLOGICAL INSTITUTE.—July 6.—The Marquis Camden, K.G., President, in the chair. The noble chairman took occasion to remind the members that their approaching Congress in London, under the special sanc-

\* *L. c.* Obs. i.

† Rust's *Magazin für die gesammte Heilkunde*. Bd. xx., 1825. Heft. 2, p. 348.

tion and patronage of the Queen, would present features of unusual attraction. Her Majesty had been graciously pleased to direct that Windsor Castle should be thrown open to the Society. Lord Camden hoped that the opening meeting in the Guildhall, on the 17th inst., would be graced by the presence of H.R.H. the Prince of Wales. The Hon. W. O. Stanley, M.P., gave a short notice of certain vestiges of the earlier occupants of Anglesey; he described some very ancient interments brought to light, about 1860, on the estates of the late R. Trygarn Griffith, Esq., at Carreglwyd. The bodies, which had been of unusually small stature, had not been burnt; they were deposited in rudely formed cists of stone, probably covered over by a sepulchral hillock. According to popular tradition, a great conflict took place near the spot between the inhabitants and the Danes. A large upright stone still marks the battle-field. Mr. Stanley placed before the meeting a photograph of a very elaborately ornamented urn found at Rhosbirio, in a grave closed in by slabs of stone; there were no ashes or bones in this beautiful vase, which is of the class designated by Sir R. Colt Hoare and other antiquaries, "drinking cups," doubtless used as depositories for food in the tomb. Specimens have been found in Derbyshire, Yorkshire, and Scotland; none had hitherto, as Mr. Stanley stated, occurred in Anglesey or North Wales. Prof. Buckman read an account of implements and weapons of flint found in Dorset, especially on his own farm at Bradford Abbas; "cores" of flint from which flakes have been struck off, also knives, arrow-heads and other relics, of which specimens were shown, occur in abundance. Of these the Professor offered a classified arrangement. Some of the arrow-heads show great skill and perfection in manufacture, and are assigned to an early period—no barbed specimen having been found. Many objects have been collected that may have served, probably, in scraping skins; others have been used as hammers, or implements of uncertain purpose. Various flints, undoubtedly wrought by man, are to be found in several parts of Dorsetshire. Mr. F. Boyle read a memoir on the ancient tombs of Nicaragua, and on the races that seem to have occupied that district of Central America. He pointed out the characteristics and distinct funereal usages of these peoples, the Chontals, by whom the mountains were inhabited, the Caribs, and the Toltecs—the latter having been the early occupants of the shores of the great inland lake of Nicaragua. Mr. Boyle described the examination of several remarkable burials, and brought numerous relics that throw light on the arts and usages of the early Indian races at a very remote period.—Mr. B. Williams invited attention to a Roll, belonging to the Hon. Fulke Greville, and showing the state of the lordships, manors, &c., in the Marches of Wales, 10 Henry VII., as enrolled in the Court of Exchequer; a document of singular interest in regard to the conditions of the Principality and adjacent counties in the fifteenth century.—A brief account was given, by Mr. G. Scharf, of the examination of the grave, apparently of one of the early abbots of Westminster, accidentally brought to light immediately in front of the high altar. A chalice and patin of base metal, with remains of the crosier found in the tomb, were shown by the Dean of Westminster, and called forth some remarks from Mr. Franks in regard to the usages connected with the interments of abbots and dignitaries in the Middle Ages.—Mr. Scharf also read a paper "On the curious historical Picture now exhibited at South Kensington, and hitherto regarded as portraying Queen Elizabeth's Visit to Hunsdon House in 1571." He pointed out, however, that it really represents the Queen's visit to Blackfriars in 1600, to do honour to the marriage between Anne Russell, grand-daughter of the Earl of Bedford, and Lord Hertford; and it is recorded that Elizabeth was conveyed from the water side in a litter borne by six knights. Mr. Scharf proceeded to identify the distinguished persons who appear in this remarkable painting, which was executed, as he believes, by Isaac Oliver, the celebrated miniature painter, long resi-

dent in Blackfriars.—Mr. J. Gough Nichols offered some remarks on the locality of Blackfriars, as seen in the picture; the details may not be given with much reality; but the house of Lord Cobham, in which the Queen was entertained, seems to be shown. It was afterwards known as Hunsdon House, and was the scene of a memorable catastrophe, by the fall of one of the floors, when an assemblage of Roman Catholics had congregated, in 1623. The house stood near the theatre in which Shakspeare was a partner. The site is now occupied by the printing-offices of the *Times*.—An account of an Anglo-Saxon cemetery, found at Melton Mowbray, and of various weapons and relics accompanying the numerous deposits, was sent by Mr. T. North of Leicester.—Mr. J. B. Waring exhibited a large series of drawings of stone monuments and illustrations of the ornamental art of the earliest periods in various European countries.—Mr. Hewitt brought some large maps of Eastern China, obtained in that country by Colonel Gordon, R.E., and found to be of the greatest precision in their details.—Mr. Dodd contributed some Italian and German MSS. of the fifteenth century; and Mr. J. Rogers sent a large medal of rare occurrence, found at Carminow, in Cornwall.

CHEMICAL.—July 5.—Prof. W. A. Miller, M.D., President, in the chair.—Mr. J. Yates exhibited and described the new standard mètres of glazed porcelain which have been recently prepared by Mr. Cassella, for the Weights and Measures Committee of the British Association. They are said to be correct to 1-5000th part of their length—show in a conspicuous manner the yard and mètre, with their respective subdivisions in juxtaposition—and are intended to serve as mural tablets.—Prof. A. W. Williamson then explained the principles of a new symbol notation adapted to the representation of organic compounds, which was criticized by Sir B. Brodie and Profs. Debus Frankland and Odling.—Mr. W. Thorp read a paper “On the Reduction of the Oxides of Nitrogen by Metallic Copper in Organic Analysis.”

#### AMENDED MEDICAL ACT.

A DEPUTATION, consisting of Dr. Burrows (England), Dr. Aquilla Smith (Ireland), and Dr. Andrew Wood (Scotland), had an interview on Tuesday with Mr. Walpole, Home Secretary, with a view to the amendment of the Medical Bill. The Medical Amendment Act, framed by the Council, and approved by Sir George Grey, was discussed. The Secretary of State gave a most patient and attentive hearing to the deputation. He had long been aware that the Medical Act of 1858 required amendment. He would look carefully through the amended Bill proposed by the Medical Council, and, if there had been time, would have attempted to pass a measure this session. He feared this was impracticable, but he should be prepared to confer with the President of the Council during the autumn, and prepare a more matured Bill for the ensuing session. The Secretary of State expressed his readiness, as far as possible, to meet the wishes of the Council, and promised to undertake the charge of the amended Bill.

### Reviews.

A PRACTICAL TREATISE ON THE DISEASES OF THE TESTIS, AND OF THE SPERMATIC CORD AND SCROTUM. By T. B. CURLING, F.R.S., Surgeon to the London Hospital, &c. Third Edition. Pp. 609. London: Churchill and Sons. 1866.

TEN years have elapsed since the appearance of the second edition of this excellent treatise, and more than twelve years intervened between the publication of the first and second editions. During the long period of two-and-twenty years Mr. Curling has therefore been accumulating materials for the illustration of the special subject with which his name is so honourably associated, and to which he has devoted the acuteness of a highly cultivated mind, and the practical experience gained among private patients and in the wards of a large hospital. The appreciation of Mr Curling's labours among our French neighbours may be inferred from the fact, that M. Gosselin, Professor of Surgical Pathology in the Faculty of Medicine of Paris, translated the second edition into French, and accompanied his translation with many valuable notes, of which Mr. Curling has availed himself in his present edition.

The increase of the matter in the book is indicated by the number of pages, which is greater by ninety than in the second edition, and the work has been thoroughly revised, and additions have been made to most of the chapters. The new subjects introduced are—Inguinal Hydrocele, Sterility, and Congenital Vascular Tumours of the Scrotum. Inguinal hydrocele is the name given to a collection of serum round a testicle, detained in the inguinal canal, or outside the external abdominal ring, and enclosed in a distinct tunica vaginalis. This affection is rare, and is very liable to escape detection during life. The chapter on Sterility extends to nineteen pages, and is a very important one. It describes successively the different conditions which may cause this affection in the male, and Mr. Curling insists strongly on its being a necessary consequence of obstruction in the excretory ducts of the testicle. He introduces a number of interesting cases in corroboration of this view, and although it can scarcely be said that he has quite decided the question, yet it must be admitted that the cases adduced very strongly support his position.

The well-worn subject of spermatorrhœa is discussed with great ability by Mr. Curling, and we need scarcely state that his opinions on the subject are entitled to the greatest attention. We should also remark that in this and other subjects treated in the work, in which some authors might be tempted to transgress the usual rules of propriety, Mr. Curling's language and precepts are marked not only by the soundest professional principles, but by the dictates of a pure and exalted morality.

We can only state, in conclusion, that every novelty, either in pathology or practice, connected with the affections of the testis, has been carefully recorded by Mr. Curling, and that the work is copiously illustrated with excellent wood engravings, and we cordially recommend the present edition to the notice of the profession.

ON DROPSY AND ITS CONNEXION WITH DISEASES OF THE KIDNEYS, HEART, LUNGS, AND LIVER; as well as some other Diseases of those Organs without Dropsy. Illustrated by numerous Drawings from the Microscope. By W. R. BASHAM, M.D., Physician to the Westminster Hospital, &c. Third Edition. Pp. 437. London: Churchill and Sons. 1866.

THE last edition of this book being out of print, and a recent publication by Dr. Basham on the “Significance of Dropsy,” having been received with favour, the author has been induced to revise and re-arrange the original work, and to incorporate with it the chief part of the text of the other volume, which, in fact, consisted of the “Croonian Lectures” delivered before the Royal College of Physicians. The title page is so copious, that the subjects discussed and explained in the text may be perceived at a glance, and it will be observed that they not only include all those diseases of which dropsy is a symptom, but also many which are unattended with that complication. The illustrative plates are very numerous and well executed, and indeed they constitute a complete *embarras de richesse*, so frequently are the same conditions repeated and displayed. The objection which Dr. Basham states has been made by some friendly critics that the illustrations of the tube-casts and cells are too clearly defined is not without some foundation, but the reasons given in explanation are to a great extent satisfactory. It is better, after all, if there be an error, to err on the side of too great distinctness than to fall into the opposite extreme, which is not infrequent in drawings of microscopic objects.

Dr. Basham's work, in its present enlarged form, constitutes a very handsome volume, containing a great mass of practical information, and is plentifully illustrated with cases. The drawings, instead of being placed at the end or scattered through the book, are placed together at the beginning, and opposite to each plate is a page explaining the figures.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 25, 1866.

### THE CASE OF DR. ALFRED WM. WARDER.

A MYSTERIOUS case, involving a suspicion of the double crime of murder and suicide, has lately occurred at Brighton, and has received a due amount of notice in the public journals. It seems to be fully understood that Dr. WARDER poisoned his wife, and it is beyond all doubt that he poisoned himself, and a coroner's jury has decided that he did so when in full possession of his reasoning faculties. He has accordingly been buried without any religious ceremony, in the darkness of night, and his property has become confiscated to the Crown, although we believe that the legal advisers of the Sovereign do not usually alienate the property in such cases from the representatives of the deceased. We have no desire whatever to become the apologists of Dr. WARDER, of whose antecedents we know but little, but we may be excused for the expression of some scepticism as to the facts either of the murder of the wife or of the felonious suicide of Dr. WARDER himself. It has been stated in the newspapers that Dr. WARDER was "a distinguished toxicologist," but if so, we must confess our own ignorance of his having achieved any such distinction; still it is admitted that he lectured some years since at the now defunct Grosvenor-street School of Medicine on Forensic Medicine. In reference to this latter statement we are informed by the *Lancet*, which probably has some knowledge of the facts, that "he tried for a short time to hold the Forensic Chair, but that he was an utter failure, and simply showed that he really knew nothing of the subject." This reminds us of the story of the Scotch newspaper which informed the public that Sandy MacPherson who was hanged for sheep-stealing in the middle of the last century, was not a Scotchman, but was born in Carrickfergus. Whatever might have been Dr. WARDER's shortcomings as an authority on Forensic Medicine and Toxicology, it appears from the *Medical Directories* that he held the position of Professor of that branch of Medical Science for ten years, from 1844 to 1854, which was certainly a sufficiently long period for his colleagues to estimate the value of his teaching.

As to the transactions at Brighton which have lately excited so much attention, we desire to express our concurrence in the general sentiment of approbation manifested towards Dr. TAAFE, for his efforts to unravel the

mystery in which the case was shrouded; but we can by no means jump at the conclusion that Mrs. WARDER was poisoned by aconite administered by her husband, even although that view was advocated by no less eminent an authority than Dr. TAYLOR, and adopted by the Coroner's jury, and endorsed by the *Daily Telegraph*. There seems to us to be nothing but negative evidence to support any such conclusion, although we by no means assert the innocence of Dr. WARDER. As to the circumstances attending the suicide of the wretched man himself, we confess that we are by no means so well satisfied as the Brighton jury and the *Daily Telegraph* appear to be, that it was a case of *felo de se*, although we do not advocate the view of his insanity. All we desire to point out is that no poison was detected in the body of Mrs. WARDER, and that it was not proved that any was administered to her; and as to the sanity or insanity of Dr. WARDER, the crucial test proposed of a post-mortem examination of his brain is simply no test at all, inasmuch as the records of lunatic asylums all tend to prove that no constant morbid indications are observed after death in the brains of lunatics, and on the other hand, innumerable cases are found in which disease of the brain is clearly traced after death where no mental aberration has been observed during life. We may also mention incidentally, that no conceivable motive can be assigned either for the murder of the wife or for the suicide of the supposed murderer, for if the statements in the newspapers are true, WARDER appears to have been in the possession of considerable property at the time of his death, and his wife's murder could have been of no advantage to him. He may, however, have perpetrated the crime for the mere gratification of a cruel propensity, and such cases are by no means uncommon.

### THE QUEEN'S UNIVERSITY IN IRELAND.

THE discussions which have lately taken place in the House of Commons in respect of the grant of a New Charter to the Queen's University in Ireland have been read with much interest by the Medical Profession in Ireland, and more especially by those engaged in teaching, or connected with our Medical and Surgical Licensing Corporations. The matter certainly involves the most serious consideration, not solely for the profession in Ireland, and our readers ought to be kept *au courant* with what has been and is about to be done.

It is almost needless for us to recapitulate the first circumstances of the Queen's University. Briefly we may say that the University itself has been simply a central examining and governing board, sitting by its Senate in Dublin Castle. It has granted hitherto the Doctorate in Medicine and the Mastership in Surgery, at the fee of £5 for each qualification, but though these licences have been taken by a considerable number of candidates, still the results attained have been very unworthy of the character of a great National University, and the system has proved a complete failure as regards the education

of "the million," to meet whose requirements the Queen's Colleges were erected. In the hope of attracting a large number of students from the neighbouring countries, Medical Schools had been established and maintained in Belfast, Galway, and Cork, at a very serious expense for the salaries of Professors, and by the Charter a protective system was provided for the advantage of these schools, a residence for three months at one of these Colleges being made compulsory on all candidates for degrees.

The response of the public to this invitation on the part of the Government has grievously disappointed the expectations of the founders of these institutions, and the experience of several years, which has been passed, has distinctly shown that local medical education "won't pay." Of the three schools Belfast has been the most successful, Cork second, and Galway last; indeed, this latter School may be said to have vegetated for its term of existence on the Dublin students, who, having plenty of time and little money at their disposal, went there to eat their dinners, and returned to pass at the Castle, obtaining a full Medical Doctorate for £5 instead of £15, the cost of the licence of the College of Physicians.

To meet this indisposition to accept the degrees of the Queen's University, its friends (and notably Sir R. PEEL) offered every blandishment in their power to students, by offering for their acceptance numerous money prizes, exhibitions, and scholarships, to pay for which a great national subscription was inaugurated. Our readers will have learned for themselves, from allusions to the matter from time to time in the House of Commons, that the proportion of these prizes to the number of students was ridiculously large—in fact, about one prize, exhibition, or scholarship to every four students, and yet it totally failed to recruit the numerical strength of the University. The fact was, that the original speculation was badly calculated: three medical schools could not live on the patronage of extra-metropolitan students, and the Queen's University had to earn for itself the prestige which was already amply possessed by Trinity College, the Royal College of Surgeons in Ireland, and the College of Physicians. The compulsory residence at the Queen's Colleges was, in fact, an incubus on the Queen's University, and the late Government determined to throw it off, and leave the local institutions to take care of themselves. With this view the Supplemental Charter was drawn up, and received the assent of Her Majesty, abolishing the essential term of residence, and throwing open the portals of the University to all comers, no matter where educated.

Our readers are, of course, in full possession of the circumstances under which the new Charter has been completed, and it is not relevant to our observations to enter into the dispute between Sir G. GREY and Mr. GLADSTONE, on the one part, and Sir ROBERT PEEL on the other, as to the propriety of the course adopted.

It is a matter of doubt whether the Charter is to be

regarded as a *fait accompli*, and its provisions irrevocably settled. About ten days since the Senate of the Queen's University met at Dublin Castle for the purpose of considering the course to be adopted, and a very animated debate took place. The Queen's College interest was numerously represented, and Sir ROBERT PEEL, as the spokesman of that section of the Senate, vehemently urged the complete repudiation of the new Charter, urging, as we are informed, that it had been enacted irregularly and unconstitutionally, and attributing in so many words the perpetration of a "fraud" to Mr. GLADSTONE. The Right Hon. Baronet, having embodied his observations by a motion of protest, Sir DOMINIC CORRIGAN addressed the Senate in support of the Charter generally, and more especially against Sir ROBERT PEEL's motion and its phraseology. After considerable discussion, the motion was withdrawn, and a second proposal for the postponement of the question till next October was passed by a majority of 11 to 3. The adoption of the Charter is therefore in abeyance for the present, and an opportunity will be afforded to Sir ROBERT PEEL to obtain explanations from the members of the late Government, and, if possible, to persuade the new Ministry to rescind the act of their predecessors.

What the fortune of the Queen's University and of Medical Education in Ireland may be will be very seriously influenced by the determination as to whether the New Charter stands or falls. In the first place, it admits of great doubt whether the Senate or the Queen's Colleges have any option whatever in the matter or can decline to accept the proposed arrangement should the Ministry be determined on carrying it out. Should they be so, it does not seem to us that the profession or the public at large can lose anything by the abolition of the local Medical Schools of Belfast, Cork, and Galway, and the University itself must gain much by the abolition of a restriction which has hitherto prohibited the growth of its influence. The Schools have been useful as fostering provincial surgery, and in so far their immediate *locale* will suffer loss, but, as educational establishments, their existence has been always a sickly one, and their demise cannot be of great import.

It is most earnestly to be hoped, however, that the provisions of the new Charter will be carried out so as to guard against the flooding of Ireland with cheap degrees and the demoralisation which the same system has effected elsewhere. The smallness of the fee itself is a source of danger. Now that the requirements which have checked its abuse have been withdrawn, and if the University allows its repeatedly evinced appetite for numerous graduates to induce it to relax its vigilance, the ruin of the profession and the depreciation of the value of its own degrees must be the inevitable result.

A SUPPLEMENT to the *London Gazette* of Friday week contains an order in Council directing that the provisions contained in the Diseases Prevention Act shall, from and after the 14th inst., be put in force throughout all England.

## NOTES OF LONDON HOSPITALS AND LONDON PRACTICE.

THE hospitals at present look "like some *marvellous* halls deserted" rather than what they were in November, or in the new start of student life after the Christmas vacation; yet there is much to give us pause as we pass along though our vigorous friends, the students, vote the thing of "walking" the wards a bore this heathenish hot weather.

A very remarkable course of lectures by Dr. Andrew Clarke, not yet finished (as there are two more to be delivered), has been perhaps the greatest novelty of the season. We are told pneumonia (the old inflammation of the parenchyma of the lung, cured by bleeding and salivation by calomel), is not an inflammation at all, but a kind of passive œdema; that there is no parenchyma in the lung; and that the patient usually gets well in spite of the mischievous effect of calomel and bleeding, a wiser but a weaker man: as our friend Mr. Skey would say in things surgical—mammary abscess to wit—there is a local *remora* from debility to be remedied rather by bark, ammonia, and wine.

Summer brings us many visitors in the wards, with whom it is pleasant to exchange notes and feelings. Of these Professor Keith of Edinburgh, the eminent ovariotomist beyond the Tweed, has set us thinking this month again about that formidable and still misunderstood and a little misrepresented operation. Keith has had forty-four ovariotomies with thirty-three recoveries, and meeting him in the instructive and excellent clinique of Mr. Baker Brown, who has had lately a run of good cases (fifteen, one after another, without a single death), it was important to note what advances in diagnosis and securing the pedicle or adhesions has been made. Our friend, Dr. Tyler Smith, it was said, has had thirty operations and twenty recoveries, and something like fifty other cases which have come under the notice of Keith, had a mortality of about 75 per cent. It is too painfully evident that everything depends on the diagnosis as to whether the case is one free of adhesions, free of malignant or uterine complications, or one of simple unadherent ovarian growth—not tapped too often—we must admit we have individually seen ovariotomies commenced that frighten us: the adhesions so formidable, the complication, with malignant growth of uterus or ovary so extensive, that death was inevitable. We have seen also cases, it is only fair to add, pronounced fibrous growths of uterus (one case dogmatically asserted to be *pregnancy*) yet turn out at the last moment typical specimens of simple ovarian tumour, and recover without a bad symptom; but, like lithotomy, we always feel a relief when the operation is two-thirds finished, and a good prognosis may be offered.

The death of the late Mr. Toynbee has produced an amount of gloom and sorrow in the profession in London that we have seldom or never observed before. Few men were so generally esteemed; and, whether we regard him as he was, as one of our best microscopists, one of our most benevolent helpers when any good work was afloat, his life was in every aspect admirable. We abstain on purpose from any exact details as to his various appointments or writings, as they cannot fail to be published already; indeed, one of the daily papers, *The Telegraph*, gives a touching and striking leading article on the case, equal to anything in any of our own journals.

If ever there was a man to whom the words of Pliny were applicable it was poor Toynbee, ever thus foremost in any benevolent design for the weaker portion of the profession, ever with a smile and manly recognition of what is true and of good report, but the hand of death is ever premature, and in his case fatally so. Those who labour for humanity with useful work, to such death comes too soon; it finds them amidst some unfinished design, *acerba semper et immatura mors, et quæ semper inchoatum aliquid abramsiat*, &c. This was truly his case. The tale told by Dr. Markham, who first saw him after the fatal event, is one of great interest. Two papers by the side of the couch on which he lay; on one was written the result of some experiments through the Eustachian tube with chloroform vapour, pure and simple, while the other paper (his death warrant) has only writing for a blank to be filled up as to the effect of prussic acid vapour.

Much doubt existed at the inquest as to whether the death was due to chloroform or to prussic acid. The post-mortem told almost nothing, as the body had already undergone rapid decomposition when it was made. Dr. Charles Kidd stated in evidence, corroborated by Dr. Leared, that prussic acid would probably have caused a struggle, and also have left traces of odour, as also reddening of the mucous membrane of stomach; the jaws would be clenched, lungs congested, pupils dilated, heart empty, &c.; whereas, under chloroform, the right side of the heart is nearly always engorged, stomach normal, pupils contracted, nor does chloroform at all accumulate in the system as some suppose. Dr. Kidd also stated that a year and a half ago he consulted Toynbee in a case of a lady with nervous deafness where he wished for a trial of electricity, but the deceased, to Dr. Kidd's astonishment, strongly recommended chloroform, which actually did the lady good. Dr. Kidd also mentioned that a case almost similar occurred not very long ago in the country, where an insurance office refused to pay a policy, as it was thought chloroform for suicide had been taken; but Dr. Kidd, from the post-mortem alone, was led to the conclusion that chloroform had not been taken, as the after-death appearances of death from chloroform, when the necropsy is made so as not to empty the vessels of the head first, are nearly always uniform, and certainly so in hundreds of experiments on animals poisoned by chloroform.

It is probable, in a word, Toynbee fell a victim to what are called "mixed vapours." The last death in America recorded is also of that nature, and the intensely deleterious prussic acid, in place of getting into the middle ear, had reached his lungs.

Of other subjects of the week we have had heavy debates by Moxon on the nature of "Vital Force;" a curious offer of twelve casks of wine to the London hospitals by a Frenchman; the Griffin Testimonial, so nobly earned and at last presented to our indefatigable friend; we have had Mr. Disraeli on the crying abuses of London workhouses, which he and Lord Derby (an Augean stable! verily) purpose to cure. We have had Dr. Taylor and Dr. Wilkes at Brighton about a wretched post-mortem of a lady supposed to be poisoned; we have the order of the Bath for Sir James Clark, M.D.

~~~~~  
In Bergen there are two large hospitals devoted exclusively to the treatment of patients suffering from a peculiar form of disease brought on by eating badly cured fish. The disease is a mixture of leprosy and elephantiasis

Parliamentary Intelligence.

HOUSE OF LORDS.

JULY 12TH.

LAW OF CAPITAL PUNISHMENT AMENDMENT BILL.

This Bill, as amended, was considered.

Lord CRANWORTH, in rising to move certain verbal amendments, said that among the crimes for which persons were to be delivered up to foreign countries was that of murder, but not that of manslaughter. Now if the word "murder" were to be changed in any degree, questions would arise in those countries concerning the legality of delivering up certain persons now handed over to the officers of justice of those countries. He, therefore, proposed to insert a clause to the effect that nothing in the Act shall be deemed to alter or effect the word or meaning of the word "murder" as far as the extradition treaties in question are concerned.

This and the other amendments proposed were agreed to, and the Bill was read a third time and passed on Friday.

JULY 13TH.

THE FACTORY ACTS.

Lord DERBY, in reply to a question from Lord Shaftesbury, announced the intention of the Government to consider an amendment of the Factory Act in relation to the employment of women and children in various manufactures to which the present Acts do not apply, but intimated that the measure, which was in course of preparation by the late Government, was not sufficiently advanced to permit of any action being taken in the present Session.

JULY 17TH.

The following Bills received the Royal assent:—Drainage Maintenance (Ireland), Burials in Burghs (Scotland), Lunacy Acts (Scotland).

The Dogs Bill was read a second time.

HOUSE OF COMMONS.

JULY 17TH.

Mr. WALPOLE, in reply to Mr. Henley, said that he proposed to take the Public Health Bill, if possible, on Thursday next.

VACCINATION BILL.

The right hon. gentleman, in reply to Colonel Barttelot, said he would state, on Thursday, the course which the Government intended to pursue on this Bill.

MEDICAL OFFICERS AND WORKHOUSE SCHOOLS (IRELAND).

Sir H. BRUCE asked the Chancellor of the Exchequer whether he proposed to relieve the Irish poor-rates from the payment of medical officers and the expenses of workhouse schools; and if so, when.

The CHANCELLOR of the EXCHEQUER said the question put by his hon. friend referred to the circumstances which were brought before their notice by the motion of the hon. member for Meath. Having been in favour of that motion he should certainly be ready to take all the steps that were necessary to afford the relief which appeared to be justly required. All he could do was to give instructions to that effect when the next Estimates were prepared.

MEDICAL OFFICERS OF THE ARMY AND NAVY.

Mr. NICOL asked the First Lord of the Admiralty whether he had any objection to lay before the House the report and evidence of the commission on the position of the medical officers of the army and navy, presided over by Vice-Admiral Sir Alexander Milne, of which a summary had appeared in the public papers; and whether it was intended to adopt the recommendations of the commission in favour of the medical officers of the Royal Navy.

Sir J. PAKINGTON replied that, so far as the navy was concerned, he should have no objection to lay upon the table the report of the commission; and as to the latter part of the question, whether it was the intention to adopt the recommendations made, he would say that it was the intention to adopt those recommendations, and that he would that evening lay on the table a supplementary estimate to carry them into effect.

SICK WARDS IN WORKHOUSES.

Mr. FAWCETT asked the President of the Poor-law Board whether it was the intention of her Majesty's Government to introduce during the present session any measure for improving the sick wards in the metropolitan workhouses;

and further, how it had happened that Mr. Farnall and others, whose duty it had been to inspect these workhouses, had not made known the lamentable condition of these sick wards until attention was directed to the subject by non-official persons.

Mr. HARDY replied that the Government did not intend during the present session to bring in any measure on the subject. He could assure the House that the condition of the sick wards in the metropolis would receive his best attention, and for that purpose he proposed to deal with the question under the powers conferred by law on the Poor-law Board. They were in his opinion very ample, but he wished to act in complete harmony with those guardians who had the charge of the sick wards of the metropolis. It might be necessary to ask for further power to make alterations and improvements in these wards, for at present it only extended to £50, and he proposed to make it £500. The powers possessed at present by the board enabled them to appoint medical officers and nurses, and to regulate their salaries; and without wishing to make any reflection on anybody, he pledged himself to the House that he should use his endeavours to remedy the evil. With respect to Mr. Farnall, a return would shortly be laid on the table which would give information as to his visits to these wards, and the general efficiency of the officers of the Poor-law.

WORKHOUSE INFIRMARIES IN LONDON.

We have much pleasure in reprinting from a late number of *Aris's Birmingham Gazette* the following sensible remarks:—

"MEDICAL RELIEF OF THE POOR.—This subject has been so fully discussed that everybody who cares about it has formed an opinion. Some of the guardians profess to see no necessity for changing the present system. Well, it would be useless to reason with men who think a penny farthing a week enough to provide medicine and a doctor for a sick man. We shall repeat the facts again, so that if the public do not heed them it will not be for want of our reiterating them. The parish medical officers are allowed fourpence for each case (*vide* Mr. Delany's speech at the committee meeting on Wednesday). The average duration of illness is three weeks. The allowance is therefore fourpence for medical attendance and medicine for three weeks. We hope we have not any readers who are unconvinced by this one fact alone that the present system of medical relief requires to be changed. We ask again, as we have already asked repeatedly without receiving an answer, how is it that at the Workhouse Infirmary, which is under the management of the Board of Guardians, the cost of each patient form medicine only (not including medical attendance) is a shilling and elevenpence, and how is it that medicine for each patient at the General Hospital costs three shillings, if the sum of fourpence is sufficient for medical attendance and medicine for an out-door pauper? It is really discreditable that it should be necessary to argue on such a question. Let the public either provide for the poor, or frankly say they will not. Why tax themselves, as they do at present, for the sake of upholding a mere form, without the substance, of relief? As to the establishment of a central dispensary, we are not wedded to that or any other system; but we object *in toto* to the plan of paying the medical officers a fixed sum and requiring them to provide the medicine. It is unfair to the medical officers themselves, because the amount of their remuneration ought to be no mere lottery, dependent on the cost of the drugs which may happen to be required during a given period: and unfair to the poor, because there will occasionally be dishonest medical officers (there have been rebellious angels), in which case the proper medicines will not be supplied. We have confidence in the good sense and humanity of the majority of the Board, and believe they will, in spite of opposition, agree to a system of medical relief which can be approved by conscientious men who really think about and care for the subject. They will hold no high place in the estimation of thoughtful and humane men so long as the present rotten make-believe system exists."

THE CHOLERA AT AMIENS.—The heat experienced on Sunday and Monday, as well as the disturbed state of the atmosphere, have exercised an unfavourable effect on the cholera patients at Amiens. The number of deaths has increased, being 55 for the two days—24 for the former and 31 for the latter.

Correspondence.

GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg now to submit my balance sheet in connection with the above. The fund was started "for the object of—firstly, defraying the outstanding expenses pertaining to Mr. Griffin's Poor-law Medical Reform Fund; and, subsequently, enabling our whole body to present him with such a testimonial as might be determined upon."

The first part of the object has been provided for by debiting the fund with £15 5s. 6d. In a letter addressed June 29, 1864, to the subscribers of the Poor-law Medical Reform Association, it appears that this balance was then due to Mr. Griffin. The second part was consummated on the 5th inst., at the Freemasons' Tavern. I have only to add that, in addition to the above £15 5s. 6d., there was a further balance in hand of £48 8s., which I have also forwarded by cheque to Weymouth. An engraving of the *Epergne* will, I trust, be in *The Illustrated London News* of Saturday, the 28th instant.

Robert Fowler, Treasurer, in account with
THE GRIFFIN TESTIMONIAL FUND.

				Balance -	48	8	0
	£222	9	6		£222	9	6

I hope you will now allow me a short space to state that I feel the time has come for me to resign the post, which for the last seven and a half years I have held, as Secretary to the Metropolitan Poor-law Medical Officers. Public and private avocations alone compel me to this. The fulfilment of the undertaking of presenting a testimonial to Mr. Griffin, I have long intended should be the termination of my active clerical labours. It is therefore but right that to those brother medical officers, who for some years have looked upon me as their representative, I should give an account of my past stewardship.

For many years the medical officers of the three city unions had been in the habit of holding monthly meetings to compare their experiences, and determine upon a common course of conduct in matters parochial, sanitary and sanatory, affecting their several appointments.

Dr. Lobb, late of the East London Union, was for many years the honorary secretary. Circumstances necessitated the dissolution of the Association, when very shortly afterwards the then President of the Poor-law Board (Hon. Sotheron Estcourt), in honourable fulfilment of his promise, promulgated his "Heads of a Scheme for a suggested New Arrangement of Medical Relief."

On January 3, 1859, by the united wishes of a preliminary committee, subsequently ratified by the unanimous vote of a general meeting of the Metropolitan Poor-law Medical Officers, I assumed and have ever since retained my representative position. The resolutions submitted by the committee to this general meeting were unanimously adopted. After four subsequent committee meetings, the course of action eventuated in a numerous deputation, which was introduced to the Poor-law President by Earl (then Lord John) Russell, accompanied by many other members of Parliament. The deputation clearly showed the President

that, through the alterations suggested, not only would our independence of action have been very vitally threatened but our professional honour and honesty would have been sorely tempted by the intended rivalry and competition. The President was convinced of the inacceptability of, and withdrew, his scheme.

Two other committee meetings were held that year. In 1860 five committee meetings were held to watch the progress of Mr. Pigott's Bill, which, by reason of the opposition of the guardians, he was compelled to withdraw.

In 1861 ten committee and sub-committee meetings were held, to devise a course of action in reference to the Select Committee moved for by Mr. Villiers to inquire into the administration of the Poor-laws.

At a general meeting, held on May 10, 1861, the statement (*vide Medical Circular*, May 22, 1861) of the committee was adopted "as the embodiment of the collective opinions of the Metropolitan Poor-law Medical Officers;" and Mr. Villiers was respectfully solicited "that certain members of the latter body be called before the said (Parliamentary) Committee, in order that they be examined on the several points contained in such statement." Of the six names forwarded, the Select Committee called upon two only—Dr. Rogers and myself—to give evidence during the last half-hour of the last day the Committee sat. Our evidence appears in the Fifth Report on Poor Relief (England) 1861; and in the Appendix to the same appears also a memorandum delivered in by myself, and which, though incorrectly and imperfectly transcribed, goes more into detail than did my evidence in chief, by reason of the very short time allowed me to speak.

In 1862 I was again examined by the Select Committee.

Of this examination it now only becomes me to say that at the very first of our two last committee meetings in 1862 I stated that, as I could no longer conscientiously advocate the per-case system of payment, to which I was of opinion the committee had pledged itself in the Statement delivered in to the Parliamentary Committee, I tendered my resignation. I added that "as my strongly expressed convictions may tend to fetter your future actions, and may conduce to the damage of the good cause, I feel that I ought no longer to hold office, and am not fit to be your representative." Nevertheless, the following resolution was carried unanimously:—"That the thanks of this committee be given to Dr. Fowler for his energetic exertions in behalf of the cause of the Metropolitan Poor-law Medical Officers, and that he be requested to continue the duties of the office of Hon. Secretary which he has so ably fulfilled."

I must now, however, again most firmly tender my resignation. The "good cause" will most assuredly suffer if it remains longer in my hands. I have no time to devote to the active duties of its metropolitan secretaryship. I hope ever to take a lively interest in the question, and shall be at all times delighted to aid in any way that my now little leisure will admit of.

It would be presumptuous to assume that the Committee of the Metropolitan Poor-law Officers then must necessarily collapse by my resignation. Should an occasion arise, I know that they who have so ably worked with me during the last seven and a half years, would not hesitate to follow a well-trusted leader.

It is right that it should be known, that during the whole period of its existence, the expenses incidental to the proceedings of the committee have been entirely met by contributions from the metropolitan men alone, without in any one instance trenching upon the funds of Mr. Griffin's Reform Association.

Now, in conclusion, let me first, as Treasurer and Hon. Sec. to the Griffin Testimonial Fund, most cordially thank the Committee, and especially the excellent Chairman,

Henry Blenkarne, Esq., City of London, for the time they have given me during half a dozen successive meetings; and especially let me express my most grateful obligations to the above 400 subscribers, who have so liberally enabled me to successfully prosecute what I two years ago undertook.

Secondly, as Hon. Secretary to the Metropolitan Poor-law Medical Officers, permit me to say that for the attention shown to my suggestions, for the invariable kindness always and universally displayed towards me, I sincerely and most cordially thank them all, collectively and individually, and hoping ever to remain in their very good remembrances, I subscribe myself ever theirs, truly and obliged,

ROBERT FOWLER.

145, Bishopsgate-street, Without,
July 16, 1866.

MEDICAL FEES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I am sure that every medical man in England and Ireland as well as in Scotland will be pleased with your remarks in the last number of your influential journal, given under the heading of "Medical Fees in Town and Country." Your observations cannot be too highly valued. If the public understood what fees their medical adviser expected previous to a long attendance, it would save a great deal of unpleasantness on both sides. There is no doubt that patients ought to pay their physicians and surgeons in proportion to their means, and a scale of fees drawn out on this principle would be highly advantageous to the public and the profession. You say very truly in your leader of the 18th instant—"Advocates have their retaining fees, the amount of which they fix for themselves. Writers have a regular and fixed scale of charges, but medical men take off their hats and beg." You likewise add—"Why should only one of these professions (meaning the medical), and that not socially the highest, decline to state what it deems their service worth?"

Some time ago there was a committee appointed by three of the medical bodies in Glasgow to examine and report on the subject of medical charges. The report, stating a fixed table of fees according to the incomes of individuals, will be found in THE MEDICAL PRESS, December 23rd, 1863. I think if you were to republish this document it would afford a useful example for future legislation, if the Colleges in Ireland would take up the matter as they ought to do for the guidance of the profession.—I remain, yours truly,

A SUBSCRIBER.

July 21st, 1866.

Notes on Current Topics.

THE CHOLERA.—As we ventured to predict last week the cholera has continued to spread. At Liverpool there have been several severe cases in the town, in addition to other deaths in the workhouse. An outbreak has also occurred at Newcastle, another at Sunderland, and a very terrible epidemic is raging at Llanely, and the neighbourhood. One of the worst cases was at Newcastle. It appears that the steamer *Otter* came into that port from Antwerp last Monday about half-past eleven o'clock. The mate of this vessel, 45 years old, went to his home in Gibson-street quite well. There had been no illness on board during the voyage. He went to bed at eleven p.m. At 12.30 was awoken by violent cramps, and these were followed by sickness and purging. He died at three p.m. the next day, having experienced all the symptoms of the most violent Asiatic cholera. It was in the same street that the first case of cholera occurred in the epidemic of

1853. At Sunderland the barque *Emander* arrived from Stettin with the captain suffering from cholera. He was taken to hospital and the vessel disinfected.

In the workhouse of Liverpool up to Thursday evening there had been eighteen deaths, and there remained in the house fifteen cases, many of which seemed likely to be fatal. The Liverpool Health Committee have adopted the recommendations of the corporation medical officer (Dr. Trench) to employ additional men in scavenging and removing filth, and to sprinkle the houses of the infected districts with carbolic acid.

London is also threatened. It has been stated that the *Queen of the Colonies*, having Asiatic cholera on board, was towed last Thursday afternoon from Gravesend Beach to the Lower Hope. Several fatal cases are reported in the eastern districts of the metropolis. The Limehouse Board of Works has issued large posters recommending cleanliness and disinfection, advising what food to avoid, and pointing out what remedies may be resorted to. In Mile-end, old Town, six deaths were registered on Wednesday last. In Stepney Union there have also been several cases. Lastly, a fully reported case has been described at the London Hospital.

On the Continent there is no improvement. Amiens, which may be taken as a specimen, added twenty-four deaths on Sunday week and thirty-one on the Monday after to the fatal record. Both days were very hot, and the weather unsettled.

POLLUTION OF RIVERS.—The Royal Commissioners have made some preliminary inspections in Leeds, Huddersfield, and Bradford. It appears that about two millions and a half of skins are dressed and tanned annually in Leeds and the neighbourhood. The fluid refuse, together with the entire sewage of Leeds, is turned into the rivers. On the meadows below the main outlet of the Leeds sewers all the live stock perished by the cattle plague. At Bradford the canals are foul with sewage and the waste fluids of the woollen factories. The same may be said of Huddersfield. In fact, all the streams of the manufacturing districts are polluted by the refuse from the factories, the dye-houses, the sewage of the towns, and even by the cinders from the steam-engines at work. Nothing is deemed improper for these receptacles. It is to be hoped, Her Majesty's Commissioners may be able to devise a remedy for this state of things.

COMMONS NEAR LONDON.—Mr. Peck has offered (through the Commons' Preservation Society) four prizes for Essays on the Preservation of the Commons in the neighbourhood of London; two prizes of £50 and £25 for the two best Essays on the Sanitary and Moral Aspects of the question; and two others of £100 and £50 for the first and second Essays treating of the Legal and Historical bearings of the question. The Sanitary Essays to be in length about 35 pages, and the Legal Essays about 75 pages of the size of the *Edinburgh Review*.

FARRINGTON GENERAL DISPENSARY.—The anniversary dinner of this charity took place at Radley's Hotel, New Bridge-street, Blackfriars, on Monday last. The Lord Mayor in the chair. A subscription list of £470 was announced during the evening.

ARCHAEOLOGICAL CONGRESS.—Several interesting

meetings have been held in London by this body. Mr. Beresford Hope's address upon "London Past and Present" opened the Architectural Section. Dr. Guest has devoted a discourse to Cæsar's passage of the Thames, stoutly maintaining opinions that differ much from those of the Emperor Napoleon. On Thursday Dr. Stanley gave a sketch of Westminster Abbey in the Chapter House of that old Cathedral. Here, also, Mr. Gilbert Scott read his paper on the "Architecture of the Abbey." In the evening Mr. Hepworth Dixon lectured at the Museum, Jermyn-street, on the "Tower of London." At the Royal Institution Mr. G. Scharf discoursed "On the Historical Paintings at Windsor and Hampton Court." A number of other papers read, lectures given, and visits made, fill up the programme. There only needs to mention the special sermon on Sunday by the Very Rev. Dean Stanley in Westminster Abbey.

BRISTOL ROYAL INFIRMARY.—Among the list of contributions last week to this charity we note, "from a lady who takes a deep interest in the welfare of the Bristol Infirmary, £1000."

BAKE-HOUSES.—The Government Report on the Bake-houses Representation Act for the year 1866, has been just issued. Great improvements as regards the health of the workmen in England and Scotland have been effected. In Dublin the Act has been zealously worked, but it has not been applied in any of the other twenty Irish towns to which it bears reference. The reply from one city was, that there was "no board of health which the Mayor was aware of." No facts could better exhibit the uselessness of permissive sanitary legislation for this country.

SANITARY STATISTICS.

MR. W. LUCAS SARGANT, who has frequently distinguished himself as the critic of plausible theories based upon an incorrect or careless application of statistics, has lately pointed out, in a letter to the *Manchester Guardian*, a serious mistake which occurs in Dr. Morgan's pamphlet on "Deterioration of Race."

"Dr. Morgan," says Mr. Sargent, "infers that the fecundity in Manchester is less than half that of Hertford. He asks us to believe that vice and disease produce such enervation as to issue in this diminution of child-bearing. I am happy to be able to show that the notion is fabulous. Dr. Morgan's statement at page 23 is as follows:—'In the next table the marriage and birth rates for the years 1860 and 1861 in the four cities are compared with those in the agricultural counties. It shows unmistakably that natural increase of population is materially influenced by different conditions of life. We find, for example, that in Manchester the average number of marriages was in the years 1860 and 1861 18.5 in every 1000 of the population; whereas there are some counties, such as Hertford, in which the rate did not exceed 5.8. On the assumption that the fecundity of the population would bear a certain fixed ratio to the number of marriages, we should anticipate a proportionately wide difference in the birth-rate of the two places. Such, however, is not the case, for in Manchester the average number of births was 37.5; in Hertford, 30.5. In other words, while the marriages in the city were nearly fourfold more numerous than in the agricultural county, the births there only exceeded the latter by about one-sixth. In Manchester there were but two children to every married couple; in Hertford, five.'"

"Nothing seems more convincing. Here are in Manchester two children to a marriage, and in Herts five to a marriage; then the fecundity of marriage is in Manchester less than half what it is in Herts. Convincing as this seems, it is really fallacious. The error consists in the confusion of marriages with married couples. It is obvious, when once suggested, that a place may have many

marriages celebrated in it of couples who come in to be married and go out again to live. I happen to have gone through this calculation before, and to have discovered the ambiguity of the result. (*London Statistical Journal*, March 1865, page 121, column 12.) I find that the births in ten years to 100 marriages were, in Manchester, 201; in Salford, 928; in Oldham, 585; in Bristol, only 175. It then occurred to me that probably the Salford people came into Manchester to be married, and went back to Salford to live; and that thus the marriages were registered in Manchester, the births in Salford.

"The question then arose, How many couples of breeding age there were in Manchester. and how many in Salford, and what proportion the births bore to these? I owed this notion to my friend Mr. J. T. Danson, of Liverpool. I found results much less abnormal. Taking, by the census, each 100 married women of 20 to 45 years old, it turned out that the ten years' births were, in all England, 299; in Manchester, 300; in Salford, 305; in Birmingham, 313; in Oldham, 305; in York, 306. In Liverpool the number was only 252; but I assigned reasons for believing that the register of births there was not to be trusted.

"It appears, therefore, by this reasonable mode of calculation, that the fecundity of Manchester is equal to that of the whole kingdom, town and country together; but that it is rather below that of some of the great towns. In this result there is nothing remarkable; and it is different indeed from the one obtained by Dr. Morgan. Manchester has vice and disease in unfortunate abundance, but these scarcely affect the fecundity of married people."

As this statement of Dr. Morgan's has been frequently quoted, and specially alluded to by some of his too trusting reviewers, we are happy to give publicity to Mr. Sargent's criticism, especially as it points out the danger of hastily forming theories from insufficiently tested statistics.

THE CHOLERA.

THE report of Dr. Simon to the Privy Council on the Public Health, contains an interesting chapter on the cholera. Believing in the contagiousness of the disease, Dr. Simon says:—

"The doctrine on this subject, which in my opinion deserves in the present state of knowledge to be accepted as practically certain—sufficiently certain, I mean, to be made the basis for precautionary measures—may be stated in the following propositions:—That when cholera is epidemic in any place, persons who are suffering from the epidemic influence, though perhaps with only the slightest degree of diarrhœa, may, if they migrate, be the means of conveying to other places an infection of indefinite severity; that the quality of infectiveness belongs particularly, if not exclusively, to the matters which the patient discharges, by purging and vomiting, from his intestinal canal; that these matters are comparatively non-infective at the moment when they are discharged, but subsequently, while undergoing decomposition, acquire their maximum of infective power; that choleraic discharges, if cast away without previous disinfection, impart their own infective quality to the excremental matters with which they mingle in drains or cesspools, or wherever else they flow or soak, and to the effluvia which those matters evolve; that if the cholera-contagium, by leakage or soakage from drains, or cesspools, or otherwise, gets access, even in small quantity, to wells or other sources of drinking-water, it infects in the most dangerous manner very large volumes of the fluid; that in the above described ways even a single patient with slight choleraic diarrhœa may exert a powerful infective influence on masses of population among whom perhaps his presence is unsuspected; that things, such as bedding and clothing, which have been imbued with choleraic discharges, and not afterwards fully disinfected, may long retain their infectious properties, and be the means of exciting choleraic outbreaks, wherever they are sent for washing or other purposes."

Speaking practically, Dr. Simon has no doubt that quarantine, conducted with extreme rigour, and with the precision of a chemical experiment, will keep cholera out of any part of Europe in which the extremely difficult conditions can be fulfilled. He is quite satisfied it ought to keep the disease out of England.

THE SUICIDE OF DR. WARDER AT BRIGHTON.

LAST week the Brighton borough coroner (Mr. L. Black) held an inquest at the Bedford Hotel, Brighton, on the body of Dr. Alfred William Warder, who poisoned himself by swallowing about half an ounce of prussic acid while in bed in the hotel on Monday night. Deceased was for some years Lecturer on Medical Jurisprudence at the School of Anatomy and Medicine, adjoining St. George's Hospital, London, and Medical Officer to the North District and Workhouse of St. Luke's, Chelsea. In 1858 he lived at Uxbridge, in 1859 at Ottery St. Mary, Devonshire, and in 1860 at Ethell, Wooton under-edge, Gloucestershire. His residences are not further given in the Medical Directory; but his second wife died at Campbelltown, Scotland. It is said she had been married to him for only eight months, and the unfortunate lady whose death is now being inquired into was his wife for but five months.

Mr. Stuskey, solicitor, Brighton, watched the case on behalf of Mr. Branwell; and Mr. Eland of Trafalgar-square, London, attended to represent Miss Gunning of Brompton, to whom deceased has confided the care of his four children, the offspring of the first marriage.

The jury viewed the body as it lay in bed in the position described by Dr. Pickford.

Mr. Richard Branwell was the first witness sworn. He deposed—I am a surgeon residing in Cambridge-road, Hove. The deceased had married my sister about five months ago. He was a doctor of medicine by profession. Did not know the age of deceased exactly, but thought about 45 or 46. The marriage was without the knowledge of our family or without the idea that any such step was contemplated, and he was an entire stranger to me till he came to Brighton. He came to Brighton about the middle of May; my sister was then with him. She died on the 1st of July. It is a fact that an inquest is now pending, and not concluded, on her body; also that an analysis of a portion of her remains was ordered by the coroner. Last saw Dr. Warder at the funeral of my sister on Saturday; but did not then speak to him. That was the last time I saw him alive. I identify the body lying up stairs as that of Dr. Warder. I had never observed in him any symptom of insanity. He was a remarkably cool and collected man.

After several other witnesses had been examined,

The Coroner said he thought the best course to adopt would be this—he would consult with the jury alone, and possibly in a few minutes they would be able to come to a decision on the question whether they would adjourn or not.

The jury consulted together for a considerable time, and on the readmittance of the public,

The Coroner intimated that the jury thought, even assuming Mr. Eland's statement as proved, that could not influence the decision as to the state of deceased's mind at the time of his death. That would be that he was not insane. However, they were willing to adjourn in order that Dr. Pickford might make a post-mortem examination, and especially of the brain, to see if there was any organic disease there. The inquest would be adjourned till tomorrow for that purpose. Supposing the brain were found healthy the jury would be fortified in their present view—which was, that deceased was of sound mind when he destroyed himself.

The inquiry was then adjourned to the following day, when

Dr. Pickford detailed the result of the post-mortem examination. Deceased's brain structure was normal and healthy, and its substance exceedingly firm. There was an absence of all evidence of disease of the brain or its investing membranes. There was an odour of prussic acid in the contents of the stomach.

Dr. Taaffe proved that he tested for prussic acid in the contents of the stomach, and found it by both Scheele's test and Liebig's sulphur test. During his four or five weeks' attendance on Dr. Warder's late wife he had never

observed even the slightest symptom of insanity about him. He had frequently talked to Dr. Warder about Mrs. Warder's illness, and considered him perfectly sane. After the post-mortem examination of Mrs. Warder's body Dr. Warder asked him for a certificate of death, and when he refused it drew attention to the appearances of the liver and brain as being sufficient to account for death. Dr. Warder also said he wished the body buried immediately, saying he did not think it would keep this hot weather.

The jury returned a verdict of *felo de se*.

The coroner ordered burial accordingly.

Mr. Eland, solicitor, suggested that the property of the deceased had been given in trust to Miss Gunning, and claimed it on her behalf for the benefit of the children of the deceased.

The coroner recorded the claim on the inquisition, leaving the law officers of the Crown to act as they might be advised.

BOW STREET.

LUNATICS IN WORKHOUSE HOSPITALS.

Matthew Crozer, an alleged lunatic, was brought before Sir Thomas Henry, the chief magistrate, on the application of Dr. Rogers, the medical officer of the Strand Union, for an order to remove him to an asylum.

Dr. Rogers observed that this was one of a class of cases in which he was frequently embarrassed by the want of proper information. A lunatic, or alleged lunatic, was brought to the workhouse gate by a constable, who handed in with him a note from the divisional surgeon, recommending his examination, as he appeared to be of unsound mind. The constable then walked away, without giving any further information as to the circumstances under which the person had been brought to the station. Many people seemed to suppose that a medical man, on the first view of a patient, intuitively perceived everything that was the matter with mind and body, but he (Dr. Rogers) could assure them that he had no such miraculous instinct. It was frequently almost impossible, without some clue to the nature of a patient's illusions, to discover that he was of unsound mind at all; a fact which some lunatics are very skilful in concealing. On a recent occasion a man was brought to the workhouse in this way, and after a long conversation he (Dr. Rogers) was unable to discover any illusion. After a renewed examination on the following day, he (Dr. Rogers) came to the conclusion that the man was of sound mind and was about to discharge him, and had left the ward to give orders to that effect, when, thrown off his guard by his apparent success, he made some absurd remarks to the ward master. The latter called him (Dr. Rogers) back and told him what the man had said. With this clue to the nature of the mania, which the patient had concealed for forty-eight hours, he (Dr. Rogers) discovered that he was a most ferocious and dangerous madman. The present was not so extreme a case, still the constable, though he was the same officer who had taken the patient to the station-house, gave no information as to the circumstances.

Sir Thomas Henry said that in future the officer who knew most of the circumstances must go to the workhouse, and give every information as to the case.

Dr. Rogers then stated the result of his own examination of the patient, from which, and from the man's own replies to the court, his insanity became painfully apparent.

Sir Thomas Henry granted the order.

DOCTORS FOR THE PRUSSIAN ARMY.—Applications have been made to the Prussian Embassy by English gentlemen wishing to enter the Prussian army, and by physicians, surgeons, and other medical men, offering their services for the duration of the present war, it is made known by the Prussian Embassy in London, that the admission of physicians, surgeons, and medical men in general, is a matter for the consideration of the General Staff Physician of the army, to whom applications are to be made at Berlin.

LATEST NEWS OF CHOLERA.

Two fresh admissions to the cho'era ward at Liverpool Workhouse on Saturday. Four more deaths on that day, making up forty-three cases, of which twenty-eight have been fatal since the 10th, nine cases of these remaining are reported convalescent. A case took place in Gregson-st on Saturday, a district up to that time quite free. The Bank Hall warehouses are now ready for occupation.

In Cheshire there is no amelioration, and cases have been reported in localities hitherto uninfected. Between thirty and forty serious cases remain under treatment at Winsford, and the whole population is suffering from diarrhoea.

Medical men in London report a considerable number of isolated cases.

On Saturday it transpired that the disease was spreading rapidly in East London. Several deaths had occurred in the principal London Hospitals. At the London Hospital cases were still coming in, and thirteen or more deaths had taken place. In Stratford ward sixteen deaths were registered by Dr. Vallance during the week; one died in six hours, another in ten from the attack. Dr. Morris had had nine cases in Canning Town and Plaistow during the same period.

The medical officer of the district, at a meeting of the board, held on Thursday night, reported forty-four cases in all. The board sat till a late hour at night, and resolved on putting in force the "Diseases Prevention Act," and carrying out the recommendations of their medical officer.

At Bethnal-green the disease is unchecked, and great complaints are being made at the absence of sanitary supervision. It is to be hoped some immediate steps may be taken to remove the filth, and enforce in the strictest manner the provisions of the Sanitary Act. The London Hospital, situated in the centre of this district, continues to receive fresh cases, and a ward has been fitted up expressly for this purpose.

In our ports there is no amelioration: at Liverpool a house-to-house visitation has been commenced; and large warehouses outside the town, at Bank Hall, have been taken to afford accommodation to families stricken with the disease.

We regret to announce that the disease has now appeared at Southampton, more than forty deaths having occurred.

Winsford, in Cheshire, is also the scene of another outbreak, above fifty cases, many fatal, occurred last week.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.---At a general meeting of the Fellows held on July 18th, the following gentlemen, having undergone the necessary examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—

Bateman, Francis, Canterbury.
Clothier, Henry, Wilmington-square.
Gill, John, Guy's Hospital.
Gorton, Jas. Keith Jeanneret, Sheffield-gardens, Kensington.
Horton, Henry James, Wrentham.
Kenyon, George Arthur, Soho-square.
Leonard, Frederick Lewis, Royal Navy.
Low, Alexander James, St. John-street-road.
Ramsford, Gifford, St. George's Hospital.

At the same meeting, it was reported by the Examiners that the following had passed the *primary* examination for the Licence of the College:

Frank Henry Laking and Jas. Frederick Parry McConnell, of St. George's Hospital; William James Bennett, Charles John Sells, William Bevan Lewis, Benjamin Walker, George Rootes, and George Stokell, of Guy's Hospital; Edward Withers Minter, John Lloyd, and David Havard, of University College; George Amsden, of King's College; James Marc Taylor, of Wednesbury.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.---The following gentlemen passed their Primary Examinations

in Anatomy and Physiology at a meeting of the Court of Examiners on the 17th inst., and when eligible will be admitted to the Pass Examination:—

Alfred Cuff, F. R. Rouse, H. C. Gill, Tempest Anderson, and A. P. Hurlstone, students of University College; Charles Lewis, J. D. Mason, A. R. S. Perkins, and Thomas Brockwell, of Guy's Hospital; Lawrence Clapham, E. S. Angove, and C. B. D. Duncombe, of St. Bartholomew's Hospital; H. A. S. Prosser and James Bradley, of Birmingham; M. F. Reilly and Thomas Wilson, of Dublin; G. C. Rigby and William Drinkwater, of King's College; W. J. Donor, of Philadelphia; P. R. Hyccock, of Edinburgh; James Ridley, of Newcastle; G. H. Jackson, of the London Hospital; Augustus Wells, of Hull.

The following gentlemen passed on the 18th inst:—

T. W. Evans, Lewis Edwardes, M. O. Coleman, R. J. Shepherd, W. F. Flowers, and A. S. Atkyns, students of Guy's Hospital; Henry Cass, J. P. Bartlett, W. R. Gowers, and C. C. Whiteford, of University College; Valentine Folwell, F. G. Guy, and S. L. Trevor, of King's College; L. M. Griffiths and C. B. Bernard, of Bristol; Joseph Moore and F. A. Fisher, of St. Bartholomew's Hospital; G. F. Jones, of the London Hospital; A. H. Newth, of St. Thomas's Hospital; D. W. Ferguson, of the Westminster Hospital; Frederick Woolhouse, of Sheffield; G. Purdey Field, of St. Mary's Hospital.

It appears that of the seventy-two candidates who offered themselves for this examination twenty-seven failed to acquit themselves to the satisfaction of the Court, and were consequently referred to their studies for three months; one candidate had an additional three months, having been discovered copying from a gentleman undergoing the written examination. The last *pass* or surgical and pathological examination for the diploma of membership of the College this session will take place on Saturday next.

APOTHECARIES' HALL.---The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on July 12th:—

Read, Arthur Walter, Arden Lodge, Coventry.
Simpson, John Henry, Fore-street, E. C.
Thomas, Owen Roberts, Liverpool.

The following gentlemen also on the same day passed their first examination:—

William Kepling, John Lloyd, David Havard, Thomas Richardson Loy, and Edward Withers Minter, of University College.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

Names of candidates who passed the Major Examination, July 18, 1866, as Pharmaceutical Chemists:—

Dumolo, John Thos., Birmingham.	Green, James Samuel, Braintree.
Forth, William, Bridlington-quay.	Hunt, Charles, Bristol.
Hodgson, William Henry, London.	Jones, William, Shrewsbury.
Pullin, Wm. Henton, Atherstone.	Kinch, C. J., Henley-on-Thames.
Cable, George Hughes, Dunmion.	Padwick, John, Christchurch.
Coleman, Alfred, Norwich.	Sandell, Thomas O., N. Hoxiter.
Corner, Robert, West Hartlepool.	Sharp, J. J., Newcastle-on-Tyne.
Doughly, Edward Thos., London.	Squire, Peter Wyatt, London.
Elliot, George, Rotherham.	Watts, Charles C., Richmond, S.W.
Farries, Thomas, Driffield.	Yates, Robert, London.
Goulden, Edward B., Walworth.	

THE ALKALI ACT.---Dr. Angus Smith has a satisfactory report on the Alkali Act of 1863. The escape of muriatic acid gas averages only 1 0889 over the kingdom; five hundred tons of the gas are evolved per day, and five tons escape, above thirty tons of dry acid per week, equal to rather more than three times that weight of liquid acid as sold. In 1864 the amount of escape was forty-three tons per week. In many works the condensation is complete. There has been no prosecution under the Act. At Oldbury the gardens suffered, and an individual brought an action, but no unlawful escape of muriatic acid could be detected.

TESTIMONIAL TO MR. E. CANTON.---The students of Charing Cross Hospital have just united to show their respect for the above distinguished member of the medical profession by presenting him with a testimonial, on his retirement from the office of lecturer on anatomy. The testimonial consisted of one of Ross's best microscopes. Mr. Canton, in returning thanks for the gift, dwelt, amongst other things, upon the vast improvement in the manners, habits, and dress of medical students since the days when they were described by the late Albert Smith.

The thirty-seventh annual festival of the Farrindon General Dispensary was held at Radley's Hotel, New Bridge-street, Blackfriars. Since 1828, 216,000 cases have received relief. Upwards of 15,607 cases were attended in the year ending March, 1866.

THE ITALIAN ARMY.---Signor Testa, the Neapolitan surgeon, has left Naples for the camp, in order to superintend the host of young practitioners who have already

joined. Great activity prevails in Naples in collecting money, lint, and bandages for the combatants and their families. The hospitals at Brescia are full of wounded men.

The number of paupers relieved last year in England and Wales on the 1st of January last was 924,813; the number on the corresponding day in 1865 being 783,661.

A MAN committed suicide the week before last, in Soho, by taking a large quantity of cyanide of potassium.

CONVALESCENT HOME, STILLORGAN.—A meeting of the committee of this institution was held on Thursday at 59, William-street, the Hon. Judge Berwick in the chair. Present—Dr. Croker, Dr. Wright, Messrs. Thomas Pim, Alexander Parker, Frederick Stokes, William Hogg, and William M. McCay, hon. secretary. Mr. Butler, architect, having submitted revised plans of buildings proposed to be erected, same were approved of by the committee and adopted, and directions were given to have the specifications at once prepared, and advertisements inserted in the newspapers inviting tenders for the erection of the buildings. The secretary reported that the subscriptions received now amounted to above £1600, and the committee adjourned to Monday, the 23rd July, to receive and open the tenders for the buildings.

Notices to Correspondents.

Mr. Griffin.—The letter is inserted.

The General Medical Council.—We have received the Reports of the Visitation of Examinations conducted by the Qualifying Bodies.

P. Q.—The Report was not published in this Journal, and we cannot, therefore, contradict the statement alluded to.

Dr. W.—The matter is altogether of a private nature, and cannot be discussed with propriety in a medical journal.

F.R.C.S.—The communication will be acceptable.

M.D.—The letter is received.

Dr. Andrew Paul.—The case will be acceptable.

The Pharmaceutical Society of Great Britain.—The note has been received.

Mr. C.—The Prize Essays on Vivisection have been received.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.
DEAR SIR.—In reporting my case of "Scrotal Hernia Complicated with Orchitis," in your last weeks' number, you were inadvertently led into a mistake as to the quantities of the ingredients which formed the mixture I prescribed—

R Liq. ammon. ant. ʒi.
Aq. lauro cerasi, ʒiss.
Tinct. hyoscyami, ʒii.
Vini antimonalialis, ʒiss.
M. Ft. mist. &c.

Whereas, if you will be good enough to refer to the manuscript of my case, you will find the quantities were the following—viz.:

R Liq. ammon. ant. ʒi.
Vini antimonalialis, ʒiss.
Tinct. hyoscyami, ʒij.
Aq. lauro cerasi, ʒiss.
Aqua camph. ad. ʒviij.
M. Ft. mist. &c.

Hoping you will be kind enough to make this correction in your next impression, I remain, yours faithfully,
W. JOSEPH HEPBURN.

WEEKLY METEOROLOGICAL REPORT FOR THE
WEEK ENDING JULY 21st, 1866.

BIRTHS.

HUGHES.—On the 17th ult., at Kirkdale-road, Liverpool, the wife of Eben. Hughes, M.D., of a son.

DIPLOCK.—On the 22nd ult., at Western House, Oakley-square, the wife of T. B. Diplock, M.D., of a daughter.

CHILD.—On the 23rd ult., at Oxford, the wife of Gilbert W. Child, M.D., of a son.

SKEGG.—On the 24th ult., the wife of J. J. Skegg, L.R.C.P.Ed., of St. Martin's-place, Charing-cross, of a daughter.

LOW.—On the 25th ult., at Martley, Worcestershire, the wife of W. C. Low, M.D., L.R.C.S.Ed., of a son.

EVERSHED.—On the 28th ult., at Amphilh Beds, the wife of Arthur Evershed, M.R.C.S., of a daughter.

WRENCH.—On the 28th ult., at Park Lodge, Baslow, near Chatsworth, the wife of E. M. Wrench, late of the 12th Royal Lancers, Surgeon, at the Duke of Devonshire at Chatsworth, of a son.

GARMAN.—On the 1st inst., at Kent House, Bow-road, E., the wife of H. V. Garman, M.R.C.S.E., of a daughter.

TODD.—On the 1st inst., at Glanton, Northumberland, the wife of J. Wm. Todd, M.R.C.S.E., of a daughter.

MARRIAGES.

COUPAR—RITCHIE.—On the 19th ult., at Leuchars, Fife, J. L. Coupar Physician, of Dundee, to Maggie, eldest daughter of the late James Ritchie, Esq., of Westfield, Fife.

SAUNDERS—BYASS.—On the 19th ult., at the Church of the Holy Trinity, Cuckfield, Sussex, Chas. Edward Saunders, M.D., of Cuckfield, to Edith, youngest daughter of T. S. Byass, M.D., also of Cuckfield.

LINDSEY—TRESS.—On the 21st ult., at St. Stephen's, Tunbridge, John B. Lindsey, L.D.S.R.C.S., of Maison Dieu-road, Dover, to Emma, widow of the late Wm. Tress, Esq., of Red-hill Lodge, Surrey.

WEEKES—HOLMAN.—On the 21st ult., at East Hothly, Sussex, Henry Weekes, Surgeon, of Old Brompton, Kent, to Harriet, youngest daughter of Henry Holman, Surgeon, of the former place.

DEATHS.

RUTHERFORD.—On the 4th ult., at Annahilt, Co. Down, Wm. Rutherford, C.M., L.M.Glas., Medical Officer of the Annahilt Dispensary, aged 66.

LIZARS.—On the 12th ult., at Ambleside, A. J. Lizars, F.R.C.S.Ed., late of Arncle, near Aberdeen, formerly Professor of Anatomy in the University of Aberdeen.

WHITTY.—On the 15th ult., at Briton-ferry, Glamorganshire, David Jones Whitty, M.D., aged 41.

BLENKINSOP.—On the 20th ult., Henry Blenkinsop, F.R.C.S.E., of Coten-end, Warwick, aged 53.

JOHNSON.—On the 21st ult., C. Johnson, Surgeon, of Lancaster, aged 63.

NEWMARCH.—On the 22nd ult., at Micklegate, York, Henry Newmarch, M.D., late Surgeon Bengal Army, aged 65.

JACKSON.—On the 25th ult., at Sheffield, Henry Jackson, F.R.C.S.E., aged 60.

DAVIS.—On the 29th ult., of bronchitis, Wm. Davis, M.R.C.S.E., L.S.A., aged 53.

CHALDECOTT.—On the 1st inst., W. Chaldecott, M.R.C.S.E., of Holmwood, Dorking, Surrey, aged 67.

WEST.—On the 4th inst., at Alford, Lincolnshire, Mary, the wife of Dr. Uvedale West, aged 57.

CLINICAL LECTURE

ON A CASE OF DOUBLE PSOAS ABSCESS, WITH WOUND OF THE FEMORAL ARTERY.

By JOHN ADAMS,

SURGEON TO THE LONDON HOSPITAL.

It is not often that these circumstances co-exist, but the accidental opening of the femoral artery occurred to me, and I take the opportunity of making a few remarks on the subject.

From the history you will observe that the case was one of double psoas abscess—that is, that there was an abscess in the upper femoral region of both sides in this poor boy, and that both abscesses communicated with this diseased vertebræ, which distinctly exhibited in the lower dorsal region a prominence which is usually designated angular curvature. Psoas abscess comes under the class of chronic abscess, and demands the most careful consideration. It is usually a fatal disease. However, now and then cases are cured, or rather get well, much to our astonishment, whilst other cases, causing but very trifling disturbance to the system, terminate fatally almost immediately after the escape of the matter by an opening made by the surgeon.

I remember a case which well illustrates this fact. A man called on me some years ago from Wales, with an immense abscess occupying the upper femoral region, which, from its history, was recognized as psoas abscess. I was about to admit him into the hospital, when some of his friends advised him to consult Sir Astley Cooper. Sir Astley at once introduced a lancet, an enormous amount of pus escaped, and the man died in forty-eight hours after the escape of the matter. On dissection the diagnosis was confirmed, and extensive caries of the lumbar vertebræ was discovered. Now, this man had walked a large part of the distance from Wales to seek relief in London. The fact was, the bodies of the vertebræ, although diseased, were capable of supporting the superincumbent column, and the spinal marrow and its nerves were intact. I make no especial allusion to the treatment pursued in this case, for I shall consider that subject presently.

Five years ago, having been sent for about seven miles from London to an operation, I was requested to see a poor girl who had been on her back an entire year, for psoas abscess depending on disease of the spine. She was much emaciated, apparently hectic, and there was an opening in the upper femoral region through which matter was escaping. I admitted her into the London Hospital, placed her on a water-bed, allowed her to assume a position most agreeable to her—namely, the semiflexed position, I gave her wine, quinine, and good diet, and she left the hospital well after many months of this treatment.

I think I am right in the conclusion to which I have arrived from the observation of many cases that, where the abscess depends on disease of the bodies of the dorsal vertebræ, the cause is more likely to happen than if the lumbar vertebræ are affected. I presume that in the dorsal region there is a more natural tendency to coalition of the bones from the direction of the natural curvature than in the lumbar region, where the bodies of the vertebræ present a natural convexity forwards. In the last case, I do not hesitate to say that the disease was in a very great measure cured by position of parts; but of course a great deal depended on the stimulus and good diet this young woman enjoyed in the hospital. In the case before us the disease has been of very long standing, and the vertebræ

have become fixed, and the abscess is probably consequent upon some access of inflammation in the body of one or more of the dorsal vertebræ, as indicated by pain at the seat of curvature and general indisposition. You will have observed that both abscesses had remained stationary for a very long time, and that all my efforts were directed to the improvement of the boy's general condition, for this purpose sea air was recommended, and he was expecting daily to be sent to Margate. However, on my visit on June 2nd, I found that the abscess on the right side had suddenly enlarged, and the enlargement was attended with great pain and tension. I therefore proceeded to open it, taking, as I presumed, the greatest possible precaution to avoid the femoral artery which is so often displaced in deep abscesses. Unfortunately, however, I not only punctured the artery but I actually slit it up for the distance of a quarter of an inch. I need not say that the escape of arterial blood in a rush, and with an audible whizz, informed me of the fact, and I at once enlarged the opening in the abscess on my forefinger, seized the structures between my finger and thumb of the left hand, and asked my colleague Mr. Maunder, who was present, to secure the artery with an armed aneurism needle. This was done with great facility after he had laid bare the artery on my forefinger. When the ligature had been applied above the wound I sought for the opening in the artery and directed another ligature to be applied below the opening. I felt now that every thing was secure, the limb was enveloped in cotton wool, and treated as after ligature of the superficial femoral for popliteal aneurism.

Let us now pause and briefly consider this case. Where was the abscess which had thus dislodged the femoral artery and raised it from its bed? Clearly it had made its way in the course of the psoas, but instead of pointing superficially, as it does most commonly, it had taken a direction deeper than usual, and most likely had made its way, as the muscle does, downwards towards the trochanter minor and along the front of the femur under the fascia lata. Anatomy teaches us all this with great precision, and believing in the possibility of such an occurrence, I had actually made the remark that before opening deep abscesses like the present, the surgeon should satisfy himself as to the position of the femoral artery. I did with my own fingers try to feel the artery, but I failed to do so. Its pulsation was no doubt feeble, and most probably the tension of the abscess from below rendered it quite imperceptible. I cannot say I erred from ignorance; but I am free to confess that I should have been more cautious. But having opened a large artery you must proceed to tie it, for no pressure, however judiciously applied, is sufficient to prevent a recurrence of hæmorrhage usually; and although exceptional cases may now and then occur, believe me there is no security against bleeding equal to the ligature when a large artery is wounded. In this case no pressure could be applied, as there was no solid body in the vicinity of the artery.

What is the treatment to be pursued in psoas abscess? Put this question to yourselves and think the case over. The disease here evidently is in the spine, the abscess is its consequence; therefore, put aside the question of the abscess and try and cure the disease on which it depends. If you can do this, the abscess may disappear, either by becoming absorbed, or you may open it. That abscesses do disappear I have no doubt. The case illustrates the position, for during the treatment of the abscess in the right thigh that in the left has altogether disappeared. I remember a case, under the care of Mr. John Scott, formerly a surgeon of this hospital, in which a psoas abscess suddenly disappeared, and the urine was loaded with pus for some days; clearly the abscess burst into the bladder or the ureter. The patient got well. It is, however, advised to let the abscess alone as long as you can, either hoping for its disappearance or deferring the opening until absolute necessity demands your interference by operation. No man likes to meddle with such cases unnecessarily.

The proper time for opening the abscess is when tension and its consequent pain render the case unbearable. How, then, are you to open psoas abscess? This question implies that there is some risk in the operation, and this really is the case. The risk is lest the patient should become exhausted by long-continued discharge, and that hectic fever should arise from inflammation of the cyst of the abscess consequent on the admission of air. Hence the efforts of surgeons have been directed to provide against this most frequent contingency. Mr. Abernethy advised that a small valvular opening should be made, the matter to be allowed to escape without pressure and by the elasticity of the sac itself, and the wound to be carefully closed by adhesive plaster; and after a short time, before the sac had refilled to its original size, that the puncture should be repeated, and a similar treatment again pursued as after the first puncture; and he hoped that by these means the cyst might contract, and the abscess might thus disappear. The plan rarely answers, and the reason is obvious—the disease of the spine still remains, and unless that gets well, which is most rare, the discharge must continue, and will, probably, eventually wear the patient out.

My advice is this—When you think it desirable to make an opening for the discharge of the matter, make one of moderate extent with a sharp-pointed bistoury, place a fomenting cloth over the opening, permit all the pus to drain away without pressing and by the elasticity of the sac itself, and after this apply a soft linseed poultice over the wound. You may use a drainage tube if you like, but the objection I have to its employment arises from its acting as an irritant in many cases, and thus increasing the discharge it was employed to diminish. Never lose sight of the general treatment of the case, by position, tonics, stimulants, and especially by sea air, or, if this cannot be obtained, residence in the country. Machines for conveyance of patients by rail are so beautifully contrived that no damage need result to the spine itself in travelling, or passive exercise, so to speak, may be enjoyed with the greatest ease in the recumbent posture on the sea beach without the slightest fatigue.

But in these cases which result so unfortunately, remember the golden rule, *Principiis obsta*. Arrest the disease when it is just beginning. Remember that long before any advance has been made symptoms will have presented themselves which ought not to have been passed over, as pain in the loins, weariness in walking, emaciation, slight febrile symptoms, dyspepsia, constriction around the chest and abdomen in the course of the spinal nerves, and others of this character, which are the certain harbingers of mischief beginning in the vertebral column, which eventuates in that most intractable affection we are now considering. This is the period for the employment of issues, rest, tonics, &c. &c., and, at this time, if steady use of these means is enjoined you may fairly expect to ward the disease off altogether.

THE rage which has prevailed lately in France for popular scientific lectures may be judged of by some figures recently published by the Minister of Public Instruction. Lectures of no sort whatever can be delivered without due authorisation in France, and between November, 1865, and April, 1866, there were 865 such authorisations granted, Paris having 235 of these to her share. Between 500 and 600 were given in Academies or under their auspices, and 152 under the auspices of the municipal authorities. As a general rule the auditory has been very numerous, frequently amounting to 500 or 800, and even reaching 1,200 or 1500, the places assigned for the lectures often proving far too small to admit all desirous of attending. The lectures were delivered by, amongst others, 2 councillors of state, 9 members of the institute, 100 professors of faculties or superior schools, 143 professors in Lyceums, 88 professors in colleges, 16 magistrates, 32 public functionaries, 22 free professors, 29 advocates, 53 physicians, 3 architects, 21 engineers, 7 priests, 3 pastors, and 3 military officers.

RICHMOND HOSPITAL.

CLINICAL SURGICAL LECTURES.

By JOHN HAMILTON,

SURGEON TO THE RICHMOND HOSPITAL, AND TO SWIFT'S HOSPITAL FOR LUNATICS.

LECTURE II.—PHYMOSIS.

WE often meet, particularly in hospital practice, with cases of acute inflammatory phymosis accompanied by chancre. In those who have the prepuce long, and who contract chancre on the inside of the prepuce, or at the corona, or the frænum, and the chancre inflames, even slightly, from dissipation or other cause, the inflammation extending to the prepuce, effusion of serum and lymph rapidly and readily take place into the loose cellular tissue of the part. The prepuce becomes elongated and inelastic, and phymosis is the result, varying according to the degree of the inflammation. We should not be too hasty to operate in these cases, as both the cause and effect may be removed in many instances by proper treatment. In the young man (Case No. 3) admitted into No. 8 ward January last, the case was of this kind, phymosis, not of great size, nor very acutely inflamed. He had had chancres for a fortnight, and had been able to draw back the foreskin; but could not do so for the last two days. There was profuse yellow discharge from under the foreskin, and when it was drawn a little back the edge of a chancre could be seen at the orifice of the urethra. Chancres could be felt over the situation of the frænum through the phymosed foreskin; they were indurated. Mercury to slight salivation, and injection of water and black-wash completely removing the phymosis and cured the chancres, and this treatment will usually succeed. I recollect, some years since, seeing a case of acute inflammatory phymosis with Dr. Gorman of Henry-street. The penis was swelled; the prepuce elongated and curled at the end and œdematous, but not very red. It was painful and very tender. A flat induration could be felt through the prepuce where the tenderness was the greatest, no doubt the seat of the chancre which he had contracted three weeks before; there was not much discharge; by the use of the local means already described, and slight salivation, he was completely cured.

The following is a well-marked example:—

Patrick Ward, a healthy-looking man, was admitted October 6, 1863, with inflammatory phymosis; the prepuce dull red, swollen, elongated, painful, and exquisitely tender, with profuse discharge of thin brownish purulent matter. The prepuce could scarcely be drawn back enough to expose the orifice [of the urethra, from which there was no discharge. Through the prepuce at the outside of the base on the right side a hardness could be felt, and the tenderness was so great that he could scarcely bear it to be examined. A chancre was diagnosed in this situation.

He was ordered five grains of grey powder three times a day, and to inject three or four times in the day cold water followed by black-wash. Under this treatment a gradual improvement took place; but immediately his mouth became sore, at the end of a week a most marked change for the better ensued; the redness and swelling nearly disappeared, and the discharge which, though changed to healthy yellow pus, had hitherto been profuse, became gradually diminished. Omit the pills, but continue injections. He left the hospital at the end of the fourth week. For a few days before leaving he could draw back the foreskin entirely so as to show the ulcers. There were five or six of small size in the granular stage and just healed. One of the largest was at the right side of the corona glandis, and was the one which had been felt, in the beginning, through the prepuce. I touched them freely with the solid nitrate of silver, and told him to take one of the pills at bedtime for another week.

I could multiply such cases, but enough has been said to prove, that we should not be too hasty to operate, as rest in bed, purgatives when required, the use of injections of water, followed by those of black-wash, or solutions of sulphate of zinc, putting a probe armed with lint and wet with a strong solution of nitrate of silver under the prepuce at the site of the chancre, and applying it decidedly to it; but, above all, the use of mercury to slight salivation, will prevent the necessity of operation, by curing the inflammation, and the cause on which it depends.

Where, however, the patient could not previously draw back the prepuce at all, or with much difficulty, before he got the chancre, it is better to operate even in these cases.

But if a case presents itself to you where the inflammatory symptoms are more intense, the penis greatly swelled, the swelling of a columnar or pyriform shape, the lesser end at the pubes, the larger below, of a deep dull red colour, rather firm to the feel, exquisitely tender, so that the patient, not only cannot bear the slightest examination, but hollows his body in to avoid the contact of the clothes; and where, when he attempts to draw back the foreskin, there is a gush, first of yellow, then of thin oily-looking fetid discharge, which discharge is profuse, saturating the dressings which are around the penis. Where the pain is great, the fever high, quick pulse, hot skin, loaded yellowish tongue, with red tip and edges, and sleepless nights, you have to deal with a phagedenic sore, the cause of the phymosis, and hidden by it, the sooner you perform the operation the better. You give exit to pus and sloughs, expose the chancre, and are enabled to use the proper local applications. Should you delay, Nature will anticipate you by more or less sloughing of the prepuce, or by perforation of it. The operation in such a case is most simple; you introduce a director under the prepuce, and passing a sharp bistoury along it, slit up the prepuce down to the corona. The same may be accomplished without the director, by blunting the sharp end of the bistoury with a small ball of wax, which probed instrument is passed flat between the prepuce and glans, to the lowest point: it is then turned with the edge of the bistoury towards the prepuce, which is rapidly divided by pushing the sharp end through the ball of wax and prepuce. Petit was the inventor of the latter method. Some prefer dividing the prepuce along the centre of the dorsum; others, thinking that a pendulous flap is left by this operation, prefer the one recommended by Celsus, of dividing the foreskin below by the side of the frænum. Where you have the choice, the latter is preferable. As the parts are consolidated by the effusion of lymph, the skin, after the division, does not retract from the lining membrane, as when the case is one of non-inflammatory phymosis, but the surface bleeds very freely. At each side at the angles of the cut at corona, and at the end of the prepuce, small arteries can be seen to furnish a rapid flow of blood. Usually this can be restrained by small compresses of lint, and when not, a needle armed with a ligature should be passed through at the bleeding vessel and tied over it. The surface of the incisions looks pale and œdematous at first, and as the inflamed prepuce is rigid, it cannot always be retracted sufficiently, immediately after the operation, to expose the sore entirely. It is, however, not absolutely necessary, as the bleeding and the free escape of sloughs, if there are any, or of the confined matter which there is almost always in the sulcus of the corona, give great ease, and much benefit the chancre.

On the third day the cut surface will be covered with a greenish exudation, and when this is thrown off it granulates and heals pretty quickly, unless it has become inoculated with the syphilitic virus, and becomes chancreous. This, I am happy to say, is rare. A bread-and-water poultice for a day or two is most useful, afterwards water dressing with lint is more convenient. Sometimes the mere operation of dividing the prepuce by letting out the pent-up sloughs and matter, removing constriction, and also, probably, by the local bleeding, arrests the phagedenic action, and the sore afterwards rapidly improves

and yields readily to treatment. A man of the name of Tyrrell, 19 years of age, and a teetotaler, was admitted into No. 1 ward, some years ago, with acute phymosis of a deep red colour, œdematous, very tender, and with oily shreddy discharge from a phagedenic chancre within; he suffered great pain. There was a chain of slightly enlarged glands in both groins, but no indication of bubo. A fortnight before he had connexion, four or five days after he perceived a chancre; the phymosis came on almost immediately after. The prepuce was divided by the side of the frænum; the bleeding not profuse and stopped by lint; no ligature required; the edges of the wound did not separate, being matted together by lymph.

The next day, at the inside of the prepuce on each side, extensive phagedenic ulceration was observed, the incision having gone through the middle of the ulcer. He was put on calomel and opium. On the fourth day the phagedenic action was stopped. On the sixth day the mouth was sore; the chancre remarkably improved, and afterwards the process of healing was most rapid. The only local application was black-wash.

In these cases of phymosis with phagedena you should ascertain, and usually it is not difficult, the situation of the chancre. You will find at one part of the prepuce greater induration and greater tenderness; the patient also will tell you that this was where he first perceived the disease. When the case has existed some days without treatment, and its progress is very acute, a dusky spot, the indication of mortification, will lead you to where perforation is at hand. This plate, from the Museum of the Richmond Hospital, shows this well, as also the remarkable elongation and distortion of the penis in severe cases.

Allow me to mention a case in point of the care with which you should seek for the seat of the chancre. A man was admitted into No. 1 ward with inflammatory phymosis and phagedena. There was evidently no time to be lost, the symptoms ran so high. I therefore slit up the prepuce by the inferior incision by the side of the frænum.

Next day a dusky spot appeared at the upper surface of the prepuce near the corona. I knew if I left this a perforation would take place, to anticipate which, I slit up the prepuce along its upper surface through the dusky spot, which was exactly over a phagedenic chancre. Finding, however, after this operation that there were ugly pen-

dulous flaps on each side, I cut them off, and thus, as it were, in three operations, performed circumcision. No doubt if I had been less in a hurry, and taken time to ascertain the seat of the chancre, and made my incision through the upper surface of the prepuce, the one operation would have sufficed.

THE STEEL FILLET.

By G. R. SHERATON, L.R.C.P.E., M.R.C.S.

THIS instrument is intended to supersede the forceps, vectis, &c., in cases of difficult parturition, where the use of these instruments is indicated. It is constructed by combining a rotatory action with the fillet principle. It consists of two blades (*a*, Figs. 1, 2, 3, and 4), of highly tempered and flexible steel, curved in a somewhat sigmoid

form, fitted and fixed into the rotatory bars (*b b*) of the handle at one extremity, whilst at the other they are united by being riveted into a linked joint (*c*), which allows each blade to rotate in opposite directions to the extent of 90°.

The rotatory bars are also formed and fitted with stops to limit their motion to 90°. The rotatory bars rotate upon the handle (*d*), to which they are fixed by nuts being screwed upon their ends to retain them in their position.

The handle (*d*) is flattened at the back part to enable the operator to determine with accuracy its relative position to the foetal head and maternal passages.

The rotatory action is obtained by pressing upon the transverse bars or "lugs" (*e*), by which the blades are formed into a hoop (Fig. 2) of elliptical form, having a short or transverse diameter of 4½ inches, and a long diameter of 5½ or 6 inches. Tractile power is obtained by placing the fingers across the transverse bars. Its application may be effected by the blades being parallel or a little apart, forming a sort of fenestrum, and is to be introduced in the same manner as one blade of the forceps or the vectis, using the same precautions and preliminary measures as with those instruments.

It may be applied over the occiput or chin as desired, when the blades are to be made to rotate by pressing upon the transverse bars, when it is converted into a hoop embracing the head. Its application is facilitated by the form of the linked joint, which renders the instrument, as it were, probe-pointed, whilst its being slightly movable renders it less liable to catch folds of the maternal passages, &c.

The flexibility of the blades allows it to adapt itself to the axis of the pelvis and the form of the head. The thinness of the blades, from the small amount of space which they occupy, is also calculated to facilitate its application. The fingers are then to be placed across the transverse bars, and tractive force applied in the direction of the axis of the pelvis.

The amount of compression upon the head is always in proportion to the amount of force required in extraction, and from the manner in which that compression is applied it is not liable to cause injury to the child.

The chief advantages and claims of superiority over the forceps are—

1. That its application is easier from—
 - a. The narrowness of its blades.
 - b. The thinness of its blades.
 - c. Its flexibility.
 - d. One blade being of easier application than two.
2. It is less liable to injure the maternal passages or the foetal head.
3. It occupies less space than the forceps.
4. It can be used without the knowledge of the mother.
5. From the facility with which it can be applied the duration of the operation is shortened.

It may be made with folding joint to render the instrument more portable, as Figs. 3 and 4.

CASES OF
URINARY AND ANAL FISTULÆ,
CURED WITH AND WITHOUT OPERATION.

By ANDREW PAUL, A.B, M.B, L.R.C.S.I.

"CAN cancer be cured without the knife?" was a question asked in the leading journal of this country, some twelve years ago, by a most amiable clergyman and accomplished divine, himself a sufferer. This gentleman had been a patient of the writer, ere this, for inward piles, and had got well.

A thunder-storm of professional wrath assailed this would-be doubter of scalpel supremacy. Yet *time*, since then, has modified very much professional opinion as to the almighty influence of the knife in the radical cure of cancer.

Just so may it turn out now, on the question being asked, "Can anal and perinæal fistulæ be cured without the knife." Professional echo will answer "No." Here then, reader, you have so many cases, as *naked facts*, from a dissentient voice.

Case 1.—In 1854, a young gentleman, in a government office, Whitehall, came under treatment, with five fistulous openings in right buttock, and two urinary openings midway between anus and back of the scrotum, the result of urethral stricture, caused, as he said, by strong injections.

A single waxed string, conveyed by an eyed-probe, was passed along the main pipe of these sinuses, tied in a loose loop, and left there. The string—seton fashion—continued in for three weeks. Surgeons in olden times found it very hard to keep a seton in nape of the neck, from ulcerating out, here the intention obviously is for the string to cut out the parts in the rear, healing as the thread advances, and curiously enough, its presence in the main tunnel, aided by water aspersion, percussion, and injection, into and against the surrounding parts—hot, when tender; cold, when not so—not only obliterated the one wherein it was, but the four tributaries as well. The enlargement of the right buttock, which, from long-continued burrowing of matter, had become twice the size of its opposite neighbour, subsided. The urethral discharge, with which the patient was literally flooded, ceased by catheterism of water percussion, and aspersion along the floor of the urethra, the stricture gave way, and, in time, the urinary fistulæ also dried up. Anal cold water injections materially helped in altering the diseased structures around. What one of us who would not rinse out his mouth after teeth-cleaning? so, likewise, the bowel, for health and cleanliness.

Case 2.—A gentleman, aged 30, called in the autumn of 1855, with urgent symptoms of retention, consequent upon stricture, in a state of spasm, the result of excessive drinking the previous night. Three years before had been treated by caustic injections for urethral discharge, that had stuck to him for six months. He begged to have an instrument passed, but was put off with the assurance of a more speedy and less painful method of immediate relief. He was seated over a shower of hot poppy-head water, from douche-jet No. 1, for about twenty minutes, when, to his amazement, a stream of water flowed from him almost involuntarily. He was desired to continue this daily and nightly for a month. Has since indulged in after-dinner libations with impunity, relying upon aspersion alone to anticipate or to meet the urgency of an attack; and has latterly been using cold aspersion with an amount of benefit such as has insured to him release from an attack ever since. This case, bearing as it does upon the previous one, is given as a proof of local anæsthesia from warmth.

By adopting this simple course, at the same time applying cold per anum, as by lavement, not only will the impression of this salutary agent be conveyed through this channel—the rectum—to the bladder, but the bowels will

be kept thereby in an easy comfortable state. Let any one afflicted with incontinence of urine from catarrh of the bladder, from prostatic disease, or from uric acid or alkaline in excess—above all, from chordee—inject, were it but a wineglassful of cold water, into the bowel, he will be astonished by the effects, from the instantaneous relief experienced through the agency of this powerful sedative.

Case 3.—A gentleman in a city bank, April, 1856, has had gonorrhœa thrice. The last time treated with stimulating injections. A fortnight after getting well, felt uneasiness and pain in the perinæum. An abscess formed and was opened by a surgeon, but the urethra was not then explored. The abscess healed up and cicatrized. It opened again the following January, and notwithstanding caustic in substance and astringent lotions, the outlet had not closed up at the time of his call. He said he wished to get well soon, as he was to be married at Midsummer. Catheters Nos. 5 and 3 failed. Having used hot water aspersion for twenty minutes, No. 10 catheter passed into the bladder with the greatest ease. On his subsequent visits, the catheter invariably passed, as at first aided only by the hot water jet. The next step was to close the fistula, and to cure the gleet, which off and on stuck to him from the first. He was enjoined to use aspersion, if possible, before passing water. On two occasions a probe, with a hole and string through its probe-end, and dipped in a weak solution of sulphate of zinc, was passed down the fistula, as far as it would go. The result was that, instead of his shirt being wetted the size of one's hand, the urine stained a surface not larger, at first, than a crown; nor, secondly, than a sixpence; ultimately, he passed water without one drop escaping through the opening.

Case 4.—May, 1864, Mr. W., from Brighton, called. Fistula in left perinæal region, leading towards the anus. Passed an armed probe, which, on reaching the lining membrane, was made to pass through into the gut, and then hooked out, the probe being unthreaded, was withdrawn, and the string tied loose. Fomentations relieved the stiffness that ensued for a few days. Mr. W. was enabled to attend business, and occasionally to come to town. Refusing to have the string tightened, or changed for a new one, the time taken to work out extended over six weeks. Sea water injections were used daily. The case ended in a cure.

Mr. W. had been cut for fistula on the right side, by the late Mr. Lawrence, and had been three weeks in bed. This case could be traced to no other cause save to regular autumnal diarrhœa, which for years he had been subject to.

Case 5.—Mr. C., aged 52, called in August, 1856; a builder by trade. He never knew what illness was that needed a dose of medicine, therefore averse to taking any.

A solid tumour the size of a marble was felt in the right buttock, with a "core" leading towards the gut, full, an inch and a half from the outlet; this was tender to the touch; no evidence at this time of matter having burst into the gut, as there was no pain at or after the closet, nor was there on the stool the slightest vestige of matter. Anal injections—warm when tender, cold after escape of matter—were the only means used during nine months; healthy action being set up, abscesses ceased to form, the opening closed, and all induration became absorbed.

This gentleman, who was seen twelve months ago, reports nothing amiss now.

Case 6.—In 1864, Mr. —, mayor of a borough town in one of the midland counties, applied for advice. Fistula underneath the fold of left buttock, leading towards the gut, which it did not penetrate. An abscess had formed nine months before, outlet closing and opening as matter formed and ceased to form in surrounding tissues. In the centre of right buttock was a second opening, leading straightforward to a depth of three inches into the buttock cushion; but unlike the other, not leading towards the gut. His health had been impaired. Scarlatina had entered his family six months ago; had been both mild and malignant in its form. My patient had it in

the throat severely; since then, health indifferent; mind depressed; was advised to have both fistulæ laid open; objecting to this he commenced cold water aspersion, percussion, and injection; in the latter the *stream* of water against the anus so relaxed the strictures as to pass in unaided by elbow-pipe, thus creating desire for stool, and to rinse out the rectum as well; this course has been pursued ever since.

For the last six months I have not seen this gentleman, though I have heard of him through the member for his borough, whose wife I have since attended for inward piles.

Case 7.—Mr. M., aged 30; strongly marked scrofulous diathesis; scars in various places, neck and chest; fistula lachrymalis of left eyelid years ago left a prominent scar; three openings in left buttock, two in right; not one leading into the gut; complained of palpitations, headache, sleepless nights, loss of appetite, occasional night-sweats; all tonics making, as he said, his head worse; nothing in the way of medicine was taken. His office-hours were light, not over-confined to the desk; still he had to breathe in an atmosphere which he found prejudicial to health—namely, that of a wholesale tobacconist. The seton healed up four of these sinuses, still fresh collections of matter formed; as a last resource, I said, “to Margate forthwith; live well, and as much on the water and in the sea-air as you can; bathe also.” He did so, in three months returning, with all the sinuses dried up; health and strength restored; since 1864 has been two voyages to America and back, as purser in a steam-ship company, wherein the writer procured for him a berth.

Case 8.—In August, 1865, Gunner R. Jury, Royal Artillery, Maidstone, came under treatment. A twelvemonth before had been in hospital, and in bed at Woolwich six weeks, having been cut three times in the right buttock for complete anal fistulæ. The string took longer than usual to work out. Why? Because of the parts being indurated through the previous operations. On the left side there was an incomplete fistula running to, as on the other side towards, the rectum. The latter I treated with seton in the presence of Assistant-Surgeon Boulton, to whose kindness and professional courtesy I feel much indebted. This case has got well, under the care of Surgeon B., to whom luckily, at the time, a similar case presented, and who introduced a string, with similar results.

Case 9.—Quarter-Master Sergeant G. Ripley, at same station, and in the same troop as foregoing, applied to me for fistula on right side, and inward piles on the left verge of the anus. I passed a seton for the sergeant; duty in the saddle called him on parade next morning, stiff though he was, yet he went through an hour's drill. Was excused from similar duty but one morning all through the treatment. His *faith* in cold water aspersion and percussion was such as that he never omitted to use it both before and after saddle exercise; this has likewise been successful. The inward piles now trouble him but little. The cure of fistula will often cure piles. These cases have been reported on to “head quarters,” by the senior surgeon of the dépôt, as evidences of treatment quite compatible both with the ordinary duties of the soldier, who is not necessitated to forego them, and as not requiring confinement to the wards of a military hospital. The attention of the military authorities has also been directed to the treatment, as the means of saving to this arm of the service many valuable men, who otherwise would be discharged.

Treatment.—1st, let us consider the *principle* on which it rests; 2nd, the *process* by which it is accomplished.

The structures in and around the anus are, even in the normal state, but of low vitality, and when diseased, are most prone to suppurative inflammation. It is extraordinary the extent of mischief entailed on this locality by neglect or by untimed treatment. Three such cases could be adduced were it necessary; one, however, is given briefly as a striking instance how mind and body become victimized. In 1838 a gentleman called from Yorkshire; repeated abscesses had formed; tardy ill-timed openings had been made; suppuration and sloughing from time to

time had so destroyed the tissues surrounding the anus that a cricket-ball could be buried in the *gulf* between the tuberosities of the ischia; the anal sphincters had been destroyed, and though all was healed over, yet on the slightest error of stomach or bowels, wind, gelatinous exudation, and liquid fæces, would escape. His object in calling was to procure some mechanical means of resisting feculent escape. Though a family man, with ample means, yet so sensitive was he on the score of effluvia, as to live in a separate wing of his mansion apart from his family, still so personally, so scrupulously clean, that the most *fastidious nose* could detect no smell. A spring-bandage and lint-pad, with aspersion and injection, so far obviated the nuisance complained of, that this patient, on calling a twelvemonth after, assured me everything had succeeded. The pillars of the rectum had assumed the office of sphincters, and that, excepting when relaxed, he had gained complete control over the exudation and had returned to family society. Before we met he declared he was barely passing through life, “now (on his second visit) I'm enjoying it.” But to return, a new and *long-continued* action must be set up. Those who fancy the knife must admit that in twenty-four hours after the operation all irritation sinks below par, requiring caustic in substance, daily and nightly dressings, relays of poultices—in hot weather most offensive—strong astringents, chloride of zinc, Condy's fluid, all combined, caging the patient for weeks—nay, months—within the walls of bed or dressing-room; whereas with string or seton, long-continued healthy action, aided by the other means, is kept up, and this at the cost of but trifling inconvenience to the patient in the pursuits of every-day life. Such is the experience of thirty years. Nor can it be said with truth that the string is much in the way during the calls of Nature. Even the act of cleansing is productive of good, as the seton is moved and drawn upon, so as to allow the escape of matter should the string cause lodgment. Once the wall of the gut becomes perfect by healthy granulation, no further escape of gas, of fæces, or of the bowel's exudation can escape into the structures around; hence a stop to suppurative inflammation. In short, after the string has cleared the bowel, and the slit has been filled up by granulation, the *bore* of the gut again becoming *patent*, neither gas, nor fæces, nor exudations, can escape therefrom. The seton enters upon its second stage—namely, to rectify and to restore to health the structures *outside* the wall of the gut, which to a certainty it will do the looser it is, the longer, therefore, will it remain in the flesh. If tightened every other day, the seton will work out in ten days, quite too short a time for the object in view—viz., restoration to healthy from unhealthy structural action, the surgeon will be beat and his patient annoyed. For what happens? The superficial parts bridge over by too hasty adhesion, the tunnel underneath remains, the surgeon has to break up the adhesions on the surface, some stimulating ointment must be applied, a torpid state of parts sets in, just as after the knife performance, and time is lost. The writer has often noticed that some patient's flesh will *rot* the string much sooner than others. So was it in the gunner's case. The seton had to be replaced thrice; whereas but lately, in the case of Capt. S. (fistula having followed dysentery in India), the second string, when withdrawn, was found as tough as a trout-line, which the Captain, another Isaac Walton, assured me would hold a good-sized fish. In the case of Mr. W., Brighton, the seton was not once changed.

2ndly. The “process,” or method of getting the seton in. In all these cases of fistulæ, whether anal or urinary, there is invariably undue crampy-action of sphincters, or of the urethral muscles; hence extreme tenderness, often amounting to torture, whether from the finger introduced, or from catheter ever so gently passed, the hot water aspersion, or, as recently, the “ether spray,” for five or ten minutes, will allay all spasm; a simple silver probe or fine gum-elastic catheter, tipped with a silver bulb, having an eye drilled in the probe end, is passed along the fistula. On

its reaching the gut there, the forefinger of either hand passed into the bowel will encounter the instrument and will hook it out. The eye of the probe is then threaded with an ordinary shoemaker's "waxed end," to which a bristle has been secured. This bristle helps the surgeon vastly to thread his probe, the waxed end is drawn through the probe eye, so as to double the string or not, as the surgeon thinks fit; the probe is withdrawn, first, back into the gut; secondly, out from the fistula. The probe is cut off, and the surgeon ties his loop, tight or slack, with an ordinary reef-knot, cutting off the ends of the waxed string, so as to be out of the way in cleansing.

If the surgeon wants to change his string, all he has to do is to loop on over the knot a second waxed end, the knot will keep the new string from slipping. With a dissecting forceps he draws the circle of the original loop round and round until the knot, holding on the loop of the new string, clears either the fistulous or the anal outlet, he then cuts the old string, and with the new one makes a new loop. Should the surgeon be summoned to a case without knowing beforehand what is the matter, if he has not got his probe in his pocket, rather than probe a fistula twice, let him ask for a lady's bodkin, which, if silver, supple, and with an eye in its bulb, will answer just as well as a Weiss's or Ferguson's probe, three or four strings of white-brown thread, well waxed, will answer his purpose: thus the surgeon kills two birds with one stone, he probes his fistula, and, at the same time, he passes his string to cure it. If the anal fistula be incomplete—i.e., not entering the gut—the moment his finger in ano meets with the head of the probe, he can scratch with his nail an opening for the probe to pass in, making the probe a fulcrum for the finger-nail to act on.

Remarks.—Incontinence of fæces—a rinderpest plague-spot to the knife—has not followed in one single instance upon the foregoing method.

That fissure, fistula, both anal and urinary, can be cured without the knife, has been, as it is to the present hour, amongst bygone and modern surgeons a *vexata questio*. To this, historical surgery, both periodical and voluminous, amply testifies. The "perineal section" has been a *casus belli* amongst moderns, north, south, east, and west in the British Isles.

Indeed, one doubts whether an individual advocating, or venturing to advocate, a peaceful mode of treatment is, or is not, an orthodox member of the "war conference." However, the writer trusts that ere the "treaty" be signed, the working of his principle will have a further and a fairer trial. As in military so in surgical warfare, routine must eventually give way to mishaps. Years may pass ere such be the result. In meantime, we must be content to escape, if we can, the casualties which "system" entails upon us. Should we, like Shadrach and Co. of old, escape scatheless from the fiery furnace, *fortune* indeed has smiled on us.

27, Mecklenburgh-square, July 20, 1866.

CASE OF CHOLERA.

By P. C. LITTLE, F.R.C.S.I., &c.

J. K., aged 51, a corpulent plethoric gentleman, residing at the sea-side some miles from the city, was suddenly attacked this morning, July 20th, with violent vomiting and purging. A few hours after the illness set in I visited him, and found him in great suffering. The stomach and bowels made strong and almost unceasing efforts at evacuation. The stools were copious, liquid, somewhat gelatinous, and nearly black. The matters vomited were acid, and deeply coloured with bile. The patient was very restless; tossed himself about; threw the bedclothes off his arms and legs, and persisted in having his head very low. For brief intervals he lay supine, resting with the vertex and heels firmly fixed on the bed. From that position he would instantly bound up, with rapid

and strong muscular convulsions, soon after which, the emesis and diarrhœa would return. His face was extremely anxious, bloated, dark, and perspiring. The eyes were heavy, half closed, rolled in their sockets, and sometimes turned upwards; the conjunctivæ suffused; pupils natural; the surface of the body was moist; the temperature equable, but higher than usual; the pulse was nervous, irregular, mean 84; the tongue was furred, white around the edge, brown in the centre; the thirst was insatiable; the urine was scanty.

I could discover no tenderness over the colon or small intestines; no collection of urine in the bladder; nor was there any unusual condition of the spine, excepting increased heat.

The history of the case seems to be of some pathological importance. The patient had enjoyed robust health up to about a year ago, when, I understand, asthma and vesicular bronchitis interrupted his happiness. Within the past few weeks he became remarkably well, and never appeared more so, or in better spirits than, on the evening before this illness. He dined heartily of lamb and vegetables, drank freely of water with a little spirit in it; and, before going to bed, partook of a draught or two of cold lemonade. Early next morning the disease burst forth, which he attributed to the lamb which was "high."

I advised the following treatment:—

℞ Plumb. acet. gr. ij.

Pulv. opii gr. j.

Pulv. aromat. gr. iij.

M. Ft. pulvis statim sumat. To be repeated in two hours, if necessary; fresh air to be freely admitted to his apartment; the excreta not to be allowed to remain in the room a moment; sinapisms to be applied to the abdomen and pit of the stomach; an ounce of brandy every second hour; cold beef-tea frequently; bits of ice to be constantly given, and a cup of strong coffee occasionally.

Next morning (21st) he said that he had derived some relief from the treatment. The powder had been resorted to three times after its first exhibition; yet he rested very little; his stomach was still sick; the bowel complaint continued; the stools had become watery and creamy in colour; the features more congested and desponding; the pupils not in the least changed, though he had taken four grains of opium since yesterday evening; the pulse was 88, but weaker. The hands and feet were cold; the abdomen tympanitic; the sudden muscular spasms and emprosthotonos still remarkable. He complained of much general distress, flatulence, pains in the great toes, a creeping sensation about the legs, and burning thirst.

I ordered a mustard foot-bath immediately, and a tumbler of hot brandy punch afterwards. The previous directions to be carried out, substituting for the powder the following mixture, a tablespoonful after each motion of the bowels:—

℞ Tinct. catechu.

„ kino.

„ opii ss. ℥ij.

Sp. ammon. arom. ℥j.

Menthæ piperitæ gtt. x.

Mist. cretæ ad. ℥viij.

In the evening he appeared to be improved; the vomiting had almost ceased, but not the diarrhœa; he cried out several times during my visit with cramps in his legs; he felt faint and more uneasy; the pulse was nearly the same but more feeble; the temperature of the feet and hands had fallen considerably lower; the features were sharp and expressive of acute pain; the eyes rolled quickly during the spasms; there was a purple hue around the mouth, eyes, ears, neck, and the nails of the fingers and toes.

I recommended the foot-bath with mustard to be repeated, sinapisms to the thighs, frictions with hot flannels over the body, an enema of starch and opium at once, and brandy punch, with a few drops of turpentine, to be given. He felt much easier after the foot-bath and the punch, and dozed awhile. I directed the astringent mixture to be

administered should the bowels move again; the other particulars to be attended to as before.

22nd: On my morning visit he was enduring great pain from the cramps which came on in convulsive paroxysms; the thighs, hips, and back seemed to be chiefly affected by them, and the breathing was much oppressed; the skin, excepting that of the chest, head, and spine, felt very cold, dry, and shrivelled; the hands and fingers were crooked; the toes stiff and pointed; the nails almost black; the diarrhoea was still urgent and attended with kneading; the pupils were contracted. I discontinued the mixture, and ordered two of these pills to be taken after each stool:

R Plumb. acet. gr. ij.

Ext. hyos. gr. iij.

Confect. aromat. gr. ij.

M. Ft. mas. Divide in pil. duo. Mitte tales duodecim. An enema of starch to be immediately given; the stimulants in larger quantities and very hot; frictions and stupes of turpentine to be persevered in.

Evening visit: The bowel complaint has ceased; the cramps have increased and have implicated the respiratory muscles; he feels a constriction around the chest and pains in the breast, with inability to breathe; the eyes are glassy and almost closed; skin all cold; the cyanotic appearances deeper; hiccup; occasional delirium and unconsciousness. I advised hot jars and other heating applications around the whole body, and turpentine punch. About midnight, after an hour's fearful convulsions with great respiratory distress, he gradually sank as if exhausted. No autopsy was admissible; but I observed that the body was livid and extremely so, and patchy over the hands, feet, face, and neck, not very unlike the post-mortem appearances which I recently remarked in a case of "Black death." Decomposition rapidly set in, and a large quantity of bloody serum flowed from the bowels some hours after death.

However unwise it may be to sound amongst the public the alarm of cholera, there can be no question as to the propriety of communicating its earliest appearance here to the profession. The present case possessed the general features of that dread disease. It was clearly defined by two periods, invasion and collapse. The former was ushered in suddenly by—

1. An increased temperature of the body.
2. Vomiting and purging.
3. Phenomena of nervous exaltation.

The second stage was marked by—

1. A lowered temperature.
2. Cramps.
3. Nervous depression.

In the first stage the great development of animal heat was very evident, and was independent of the violent peristaltic and convulsive movements; for, in the intervals of comparative ease, the temperature was undiminished, and the vomiting and purging did not appear to be primary actions, but secondary, the result of a great nervous force, a *vis a tergo* abnormally acting. This view is strengthened by the sudden nervous commotions and convulsions which immediately preceded an attack of emesis and diarrhoea; by the continuation of the latter conditions after the viscera had certainly cast off all ingesta; and by the character of the ejections, which, as regards the stools, were opaline—to all appearances the chyle and other constituents of the blood; and, as regards the stomach, were bile, mucus, and probably gastric juice. We are, therefore, disposed to consider cholera as primarily affecting the nervous system, and are forcibly led, by its many points of similarity, to associate it with a large and obscure class of diseases referrible to spinal lesion, and whose pathology may be found in the loss of balance between the cerebro-spinal and sympathetic systems, the former preserving a preponderating influence. In a recent number of your valuable journal we advanced this view regarding cerebro-spinal arachnitis, and it is gratifying to observe that it has since been adopted by so well-known a pathologist as Dr. Lyons.

Viewing cholera in the same pathological aspect, we may consider the symptoms of the period of invasion as indications of a conflict between the two nervous systems, in which the sympathetic, overbalanced by the foreign element, yields more or less to the cerebro-spinal system. In the second stage the sympathetic is quite disorganized, the cerebro-spinal is consequently uncontrolled; and this brings us to inquire into the origin and nature of the nervous lesion in cholera.

It is most likely the disease is a contagion, as Mr. Simon and other distinguished nosologists hold. This opinion is verified by the fact that, in the early outbreaks of the present epidemic in England, and on the emigrant ships between this country and America, the disease first manifested itself amongst persons who had recently come from infected continental ports. It afterwards extended to the attendants upon such patients, and then to others. But what the nature of this contagion may be is yet a matter of speculation. It is probably an animal poison, introduced into the system through the medium of air, water, or food; and there is every reason to believe that the development and diffusion of the morbid matter are favoured by certain atmospheric, hygienic, and individual conditions. An epidemic constitution of the atmosphere has been often observed to precede cholera, and we have been for some time apprised of the existence of such aerial condition by epidemics amongst the lower animals, and by such diseases as febris nigra and arachnitis amongst ourselves. That hygienic and personal states influence the spread and fatality of cholera is clear from the disease breaking out and proving most destructive in localities in England in which sanitary arrangements are most neglected, and amongst persons whose constitutions have been subjected to deteriorating physical, moral, and mental agencies. Amongst the latter fear seems to be a strong predisposing cause.

What is the *modus operandi* of this poison? Does it prevent the proper aëration of the blood? or the elimination of carbonic acid?

Whatever may be its mode of action, its chief effects appear to be a suspension of the sympathetic power over the capillaries, a consequent blocking up of these vessels, and a cessation of their secretive and excretive functions. In the first stage the capillaries seem to resist, to the utmost, the depressing effects of the poison, which may explain the great increase and evolution of animal heat, the excretive efforts of the alimentary canal, and the high nervous phenomena which usher in the disease. The elimination of the poison through these vessels in some cases is not as rapid as its development, owing to weakness of the sympathetic system in such individuals. The consequence is an accumulation of the poison in the system, a suppression of the secretions, as of urine, and the establishing of all the features which indicate the second stage of this malady.

As regards the case under consideration, there is no doubt there were many causes predisposing the patient for epidemic disease. The lowered tone of his nervous system, through his recent delicacy; his asthmatic tendency; unusual mental anxiety; together with the injudicious use of certain kinds of food, and the likelihood of the water supply being impure, would give ready access to cholera. And how may the contagion have been contracted? Possibly from an English tourist travelling in one of our railway carriages with deceased; or more likely, from one of his own family, who, a few days before, had come from England, and soon after his arrival suffered from unusual derangement of bowels and stomach.

The nurse in attendance upon deceased became affected with choleraic diarrhoea and vomiting, and subsequently with coldness of the extremities, but no cramps. Another attendant in the house became similarly indisposed. The locality is considered very healthful, yet I have been informed that an epidemic has recently been noticed amongst fowl there. The poor birds drop from their roost, flutter about, and expire in convulsions. I myself

remarked at the time of this case, low land fogs prevailing in the neighbourhood.

The foregoing observations aim at the discovery of a true basis of treatment, which is to be found in pathology alone.

In our diagnosis and treatment of this case, we were guided by the early symptoms, which were those of diarrhœa and emesis. This view, taken with the absence from this country of epidemic cholera, indicated the remedies we applied; and the same would have been resorted to by the majority of practitioners in the first stage of cholera. Our diagnosis was modified on the appearance of the "rice-water" stools and the cramps. The treatment was then in every way stimulating. The mustard foot-bath alone afforded the patient some temporary relief. Had I, in the outset, suspected this to be a case of epidemic cholera, I should have directed my treatment to the eradication of the poison, in accordance with the views above expressed. To that end I should probably have commenced by abstracting some of the poisoned blood from the spine by leeches, with the object of gaining time for the action of the antidote upon which I rely—mercury, quickly given to salivation, in the form of calomel with opium; or by rolling the patient in a sheet covered with mercurial ointment. The power of this medicine in neutralising animal poisons in the system is well established, and why should it not act similarly as regards cholera poison? Of course such treatment would be very injudicious in the stage of collapse.

Much has been said of the efficacy of ice to the spine. I can appreciate its mode of action in cases of mere spinal excitement, or in arachnitis; but I cannot understand how it could remove a poison from the system. It might, by lowering the spinal energy, delay the development of the toxic agent. It could not eradicate it. "Cases have recovered under its use;" others have failed. Under every form of treatment, and without any treatment whatever, some patients have recovered and some have died. However, it might be desirable to test and accurately note the effects of the application of cold to the spine in cholera, should opportunity offer. And, on account of the many inconveniences in the use of ice, not to speak of the difficulty of getting it sometimes and in some localities, I would suggest the application of Richardson's ether spray along the spine, through some well constructed, easily-worked instrument. Such an apparatus would certainly be of great advantage in cases of spinal arachnitis or kindred diseases; and it might be of some benefit in the treatment of the early stage of a disease of blood poisoning, and which has so far baffled medical science.

1, Lower Dominick-street.

Hospital Reports.

LONDON HOSPITAL.

CASE OF PSOAS ABSCESS: WOUND OF FEMORAL ARTERY.

(Under the care of Mr. ADAMS.)

[From Notes by Mr. WILLIAM E. DITCHETT.]

ON March 20th, Charles Moore, a weakly-looking anæmic boy, æt. 11, was admitted into the hospital. On examination there was found to be a fluctuating swelling in the left groin, a little below Poupert's ligament, which communicated an impulse on coughing, and diminished in size when the patient lay down. In the right groin there was a little tenderness and swelling, with rather obscure fluctuation. There was considerable angular curvature of the spine about the last dorsal vertebra. He complains of

pains in the back and loins. He is ordered the ol. morrhuae, ʒi. and vin. ferri, ʒi., and full diet. His mother tells me that until five years ago he had very good health, when he gradually became thin and weak. He attended as out-patient at the Victoria Park Hospital. During some time he had been complaining of the pain in the back. His mother now first began to notice the projection of the spine. He cannot remember any accident to account for it. Three years ago he was a patient in this hospital, under the care of Mr. Critchett. The back was treated with setons, and after six weeks he left the hospital somewhat relieved. He says the swelling in the right groin commenced about six months ago. He first noticed a little soreness and swelling in the right thigh a day or two before admission.

March 22nd: As the patient cannot take the cod-liver oil it is discontinued; he is still to take the steel wine.

June 2nd: The patient continues about the same; the abscess in the left groin has increased but slowly; the one, however, on the right side is considerably larger, extending some distance down the thigh. Mr. Adams, therefore, determines to open it. Before performing the operation he told the class that great caution was necessary in opening abscesses in this region, on account of the danger of wounding the femoral vessels. As no pulsation could be detected after a careful examination, Mr. Adams made an incision parallel with the long axis of the limb. A gush of pus and blood immediately followed; Mr. Adams plunged his finger into the wound (and the artery being compressed), enlarged his previous incision, and laid bare the vessel in which was a longitudinal incision about a quarter of an inch long; a ligature was then placed above and below the wounded part.

The boy has since improved, the abscess discharged freely for some time, but the one in the opposite thigh has gradually disappeared. There was no secondary hæmorrhage. The ligatures came away three weeks after the operation.

July 20th: The boy feels in much better health than when admitted; he feels stronger and has less pain in his back. Both the abscesses have disappeared, and the wound in the thigh is nearly healed, and he is discharged to-day, and ordered to go to Margate.

CITY DISPENSARY.

CASES TREATED BY ACONITE INTERNALLY.

(Under the care of Dr. PROSSER JAMES.)

Case 1.—A boy, æt. 13, seized with febrile symptoms on Monday; admitted the following Wednesday, complaining of sore throat and feverishness. Skin hot and dry; tonsils large and tender; whole fauces intensely congested; tongue "strawberry;" pulse full, 120; cough. Tinct. aconiti. ʒvj.; aq. ʒiij. M. Sumat. ʒij. Stia quaque hora. On his next visit he was much better in every respect. The pulse had fallen to 98. One week after he commenced the treatment was discharged cured.

Case 2.—John B., æt. 35, after exposure to cold and wet, was seized with shivering, followed by heat of skin. On second day of illness was admitted with fever and sore throat. Voice reduced to a whisper; tenderness on touching the thyroid cartilage; fauces fiery red; tonsils somewhat swollen; with laryngoscope redness seen stretching down the larynx to vocal cords; epiglottis swollen and congested; pulse 110, full. Two drops of tincture of aconite (P. Lond.) to be mixed with a little powdered sugar and laid on the tongue every three hours. After eight doses complained of tingling all over. Congestion of throat nearly gone; voice better, but hoarse; skin cool and comfortable; pulse 80, small, compressible. Omit the medicine. The third day discharged cured.

Case 3.—Thomas —, æt. 20, usual health good; states he has caught cold; on admission is very hoarse; has redness of fauces; tenderness over thyroid, and congestion

of larynx on inspection by laryngoscope; skin hot and dry; throat; pulse 95, full and hard. Three drops of the tincture mixed with sugar placed in his mouth. Numbness soon supervened; then a sensation of "pins-and-needles" all over him. About four or five hours later applied again, being frightened by these symptoms, besides a constant desire to swallow and fits of suffocative cough. On inspection the injection had gone, the velum lay loosely on the tongue, as though it were paralyzed—accounting for the desire to swallow and the cough. Pulse soft, 72. To take no medicine, but gargle the throat now and then with pure water. Next day all his symptoms had disappeared.

Case 4.—Henry —, æt. 53, admitted November 1st, having been ill a week with pain in the side, cough, and expectoration. The pain is dull, and continued all over right side. Breathing very short and laboured; pulse full, 120; tongue furred; bowels open; expectoration "like white of egg," once a little rusty-coloured. On percussion and auscultation there is dulness and crepitus all over right back. Tinct. aconiti $\mathfrak{m}xv$; aq. $\mathfrak{z}xij$. M. $\mathfrak{z}j$. 4ta quæque horâ.

Nov. 5th: Pulse much less full, only 86; all below the level of right nipple tubular breathing, with here and there points of crepitation. The whole inferior half of right back presents also tubular breathing and bronchophony. Cough troublesome; expectoration quite white. Continue the medicine.

8th: Pulse 80, soft and compressible; otherwise much the same; feels some numbness in his fingers. \mathfrak{R} Pil. conii comp. gr. v. ter die sum.

12th: There is some increase of voice-sound over the right back, but no moist râles can now be heard; the numbness has not nearly gone from his two middle fingers; the cough is slight and easy; skin cool; no pain; all functions comfortably performed; was desirous of being discharged; was therefore discharged with a few more pills, and directions to take care of himself.

REMARKS.

These cases illustrate very well the practice of Dr. P. James in the internal use of aconite. He has employed it in several thousand cases of various diseases—mostly those in which there is increase of the heart's action. He employs it frequently as a febrifuge instead of salines, attributing to it the power of reducing the pulse and relieving the whole train of febrile symptoms. It is particularly useful as possessing certain anodyne qualities. There are few diseases in which the experiment has not been made. All cases characterized by nervous excitement seem to be benefited. Many forms of palpitation are at once cured. Dr. J. has frequently used it in organic cardiac diseases. In his practice aconite takes the place of digitalis as a controller of the circulation, in addition to the place of salines as febrifuges. The sensation of "pins-and-needles" shows that the drug is acting on the system, and on the appearance of this symptom it should be discontinued or the dose diminished. It is to aconite what salivation is to mercury, or muscular twitchings to strychnine. Its powerful action on the heart is shown by the rapid fall of the pulse in each of the cases reported above. Its local action on the fauces is well seen in Case 3, while in Cases 2, 3, and 4 the numbness was produced by a few doses.

MATER MISERICORDIÆ HOSPITAL.

CASES OF PHTHISICAL HÆMOPTYSIS.

(Under the care of Dr. HUGHES.)

Case 1.—A young man named J. Carey, aged 24, was admitted into the Mater Misericordiæ Hospital on the 4th May, 1866, under the care of Dr. Hughes. He had been spitting blood very freely every day for the previous week, and felt weak and nervous. He was a tall, good-looking, well-conditioned young man, with a high complexion, fair

delicate skin, and dark (almost black) hair and eyes. He was of regular and temperate habits, an only child, and lived in the country until within the last two months, when he came to Dublin to fill a commercial situation. Last autumn he caught cold, and from that time had cough with expectoration. He was under medical advice and taking cod-liver oil for months up to the time the hæmoptysis occurred. The expectoration of blood came on suddenly without any provocation, either from external violence or as the result of any unusual exertion. It was stated that his father died of phthisis, but his mother is living and healthy. On admission into hospital it was evident that he was suffering from great constitutional disturbance. The countenance wore an expression of anxiety and apprehension. The breathing was short and hurried; the skin pale, hot, and dry; the pulse small, quick, and compressible, beating 110 in the minute; the tongue furred; bowels costive; urine scanty; thirst urgent; appetite gone. There was cough with expectoration, mostly bloody, or rather consisting of pure blood, with an occasional admixture of muco-purulent matter. The cough was most troublesome towards evening and during the night, but generally abated in the day-time; it was, however, even then easily excited by talking or any mental emotion, when blood was invariably expectorated. On examining the chest, which was narrow and badly developed, there was no difficulty in discovering the physical signs of a cavity in the apex of left lung situated towards its posterior aspect; and that this was the result of tubercular disease was inferred both from the history of his case and the constitutional symptoms. The opposite lung was apparently healthy. Without any delay an endeavour was made to control the bleeding, and every means was employed to that end; perfect quiet, rest in bed, with the shoulders raised; ice and iced drinks; cupping over the chest, followed by blistering; purgatives to empty the alimentary canal; acetate of lead in small and very large doses, with opium and hydrocyanic acid; gallic acid; turpentine—were all tried, and in the order above mentioned, without producing the slightest beneficial effect. At every succeeding morning visit almost the same quantity of blood was produced, and the patient gradually lost ground until at last he sank from pure debility on the thirty-first day after his admission and the thirty-seventh from the commencement of the hæmoptysis, and it may be stated without any exaggeration whatever that he lost on an average six ounces of blood each day while he was in the hospital.

A post-mortem examination was made twelve hours after death, and after the facts already stated it seems unnecessary to add that the body was remarkably ex-sanguineous. There was no morbid adhesion of either lung; in the apex of the left lung, beneath the place which afforded the stethoscopic phenomena, there was a tubercular cavity about the size of a small orange, filled with a clot of blood of soft consistence, and the bronchial tubes opening into it were plugged with coagula. The remaining portion of this (left) lung, and also the right, were perfectly healthy, with the exception of a very few miliary bodies deposited in apex of latter, but both were completely drained of blood; not a drop of blood or serum exuded when they were divided, and they appeared exactly like the emphysematous portion of a lung which had long suffered from chronic bronchitis, both as regards their pale colour, absence of blood, and specific gravity. The heart was very small but quite healthy, without any blood in the right cavities, but with a small coagulum in the left ventricle. It was intended to have injected the left lung, as there was no doubt the hæmorrhage proceeded from rupture of a large bloodvessel opening into the tubercular cavity; but the examination was made under considerable difficulties, and there was no apparatus procurable in sufficient time for that purpose.

In connexion with the foregoing the following case, copied from Dr. Hughes's hospital case-book, is interesting:—

Case 2.—On the 26th January, 1864, a sailor, named

William Murphy, 19 years of age, was admitted into the Mater Misericordiæ Hospital. The gentleman who recommended him to Dr. Hughes wrote that he had been found a few days before on the roadside near Dalkey station, "lying in a pool of blood." On admission he stated that he had served two years in the Royal Navy, from which he had been discharged some three or four months before as unfit for service because of diseased chest. His habits of life were not temperate. His father was alive, but his mother and brother died of decline. He was a tall well formed, muscular young fellow, and he never suffered from any illness until this cough came upon him, about eighteen months ago, and never left him since. He thinks he contracted the cold while serving on the African coast, where he indulged as freely as he could in intoxicating drinks, and that it was aggravated by the same habits since his return home, four months ago. The hæmoptysis occurred while he was hastening to catch the train at Dalkey, and was very considerable in amount, he says "a couple of quarts." He felt extremely weak and exhausted for some days subsequently, but feels now greatly recovered, as he is able to stand up and walk a little. The cough is still very troublesome, but there is no blood expectorated. He has little appetite, and sweats very much at night. On examining the chest the physical signs of suppuration in apex of left lung were very plain. On the right side, also, there was comparative dulness beneath the clavicle and tubular breathing. There was no abnormal sound heard in the præcordial region, and there was no abdominal complication. The pulse was 120, small and weak, and the patient was very nervous and excitable. On the fourth day after his admission into hospital there was a slight bleeding, which readily yielded to appropriate treatment, and the patient made a considerable progress for a fortnight after. His appetite improved, his strength increased, and his excitability diminished; so that it was expected his case would assume a chronic form and follow the usual course of tubercular disease of the lung. Under those circumstances he was anxious to return home, and there was no objection made to his doing so, for his condition did not excite any apprehension as to a sudden termination, and the only unusual symptom remarked was the quickness of the pulse, which never fell below 120, and frequently ranged higher. He spoke about leaving for some mornings, and ultimately fixed the 20th of February as the day on which he would leave. He walked about the ward on the 19th, ate and drank as usual, and was examined at the morning visit on that day without anything new being discovered. He went to bed at nine o'clock and slept some hours, until between one and two o'clock a.m., when the patients beside him were aroused by hearing him make a noise trying to get out of bed. They at once summoned the night nurse, and she found him leaning over the side of the bed throwing up blood and gasping for breath. In a few minutes he died in her arms suffocated, twenty-eight days after the first attack of hæmoptysis occurred.

Post-mortem examination.—All the air-passages were filled with blood; the larynx, trachea, and larger bronchial tubes were so filled as to exclude the passage of air. The left lung was extensively diseased, and large vomicæ were found in the upper lobe. In the apex of the right lung, also, there was a large amount of tubercular deposit, but no cavities. The heart and abdominal organs were apparently healthy.

In these two cases the mode of death was different, but the cause the same. In the one the hæmorrhage was directly fatal; in the other indirectly. That a large vessel gave way in both can scarcely be doubted, not alone from the way in which the loss of blood occurred, but also from the inspection after death. It has been stated by some of our best authorities that pulmonary hæmorrhage happens much more frequently as an exhalation from the bronchial membrane than as the result of a ruptured vessel. This is, no doubt, quite true, and accords with one's every-day experience. We very frequently meet with hæmoptysis as a symptom in connexion with tubercular disease, gene-

rally speaking moderate in amount, readily controlled by remedies, and even often serviceable in relieving local congestion; and we cannot doubt that in such cases there is no broken vessel. But when the loss of blood is large in amount, sudden in its occurrence, and, above all, when it proves fatal, as in the foregoing instances, even although we are unable to demonstrate the ruptured vessel, it is impossible to doubt the source of the hæmorrhage; and it is well to bear in mind that such a contingency may happen, although, fortunately, very rarely: so seldom, indeed, that Dr. Walshe says, "My analysed series of 131 cases furnishes but two examples of such mode of death; one from asphyxia, the other from exhaustion; both were males." The records of the Mater Misericordiæ Hospital for the last six years, furnish only those two examples of fatal hæmoptysis in connexion with phthisis; and one other in the surgical wards, under the care of Dr. Cruise. This last instance occurred in 1861 in the person of a man over sixty years of age, named Brady, who was sent from the country, and whose case was diagnosed as one of advanced phthisis. He died suddenly of hæmoptysis, producing suffocation, and the post-mortem examination verified the diagnosis as to the disease and cause of death.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

ORGANIC CARDIAC MURMURS—DISAPPEARANCE OF.

Case 1.—J. M., aged 18, female, unmarried, a domestic servant, was admitted into the Whitworth Hospital, labouring under well-marked rheumatic arthritis. She had on two previous occasions, at intervals of about a year each, suffered from the same malady. When examined the principal joints were found to be affected, and some distress and uneasiness were complained of in the præcordial region, and pain was elicited when pressure was made over the heart. On applying the stethoscope a slight but distinct double friction sound was audible. The patient was placed on the combination of the salts of potash in infusion of gentian, referred to in former notices of Dr. Lyons's Clinique. Opium was administered in quarter-grain doses every fourth hour; the joints were poulticed with chamomile flowers and poppy-heads, and three leeches were placed over the heart. Very great and speedy relief to all the symptoms followed the use of these measures, and the cardiac phenomena in particular exhibited a marked amelioration. Two days subsequently the double cardiac friction sound was found to have entirely disappeared; but a single systolic murmur was now audible over the aortic orifice, and propagated a short distance up the line of the aorta. While all else about the case promised most speedy convalescence, Dr. Lyons observed that the presence of a systolic cardiac murmur greatly complicated the prognosis. The occurrence of any form of cardiac implication must be ever regarded as a serious addition to the weight of responsibility attaching to the practitioner who has to deal with cases of rheumatic arthritis, and though pericardial affections are not found to be of the necessarily fatal character, immediately or remotely, of which they were once supposed to be, the presence of such a lesion is an unfavourable element in any case in which it is presented. That pericardial lesions terminate favourably in a large number of cases (contrary to the statements and opinions of Hope) is now well established to the satisfaction of all practical physicians. But in regard to endocardial lesions no such favourable issue can in general be predicated. It is usually assumed that once deposit is established upon the semilunar or mitral valves, the case progresses in a downward direction and with a rapidity proportionate to the amount of physical impediment to the circulation through the orifice engaged. That this is usually but too true, the daily records of hospital and private practice attest.

The case of the patient now under consideration is important, inasmuch as it shows a more hopeful result. It is unnecessary to follow out its daily history. Suffice it to say, that under the treatment above indicated, with a renewal of the application of leeches over the heart, marked and rapid amendment took place in the arthritic state and the general pyrexial condition. The systolic cardiac murmur continued well marked for a period of about ten days, and was still clearly observable after the patient was sufficiently convalescent to sit up and walk about. Her medicines were now changed for bark and iodide of potassium, with local application of the tincture of io line over the præcordial region. Day by day the cardiac murmur lost its intensity, until finally it could be but faintly distinguished, and then only by those who had been familiar with its character during the earlier periods. To strangers, and she was on several occasions examined by well-practised auscultators, no murmur was recognizable. This patient left hospital fully convalescent, and with no lesion of the heart discoverable by the stethoscope.

Case 2.—This patient, a young man, aged 26, married, was admitted with other applicants to the Hardwicke Hospital. When examined he was found to exhibit all the phenomena of well-marked rheumatic arthritis with implication of all the main joints and several minor ones subsequently. Slight systolic cardiac murmur was observable over the aortic valves, and a good deal of suffering referable to the heart had been experienced for some days and nights prior to admission. This patient was treated by the combination of potash salts and opium internally, with poultices to the joints and leeches to the heart already referred to. In no case was more immediate and decided relief experienced to the local symptoms in the joints. The heart likewise was sensibly improved, in so far as regards its pulsation and the sufferings complained of; but day by day the murmur became more and more distinct, until a well-marked and perfectly unequivocal systolic bruit was audible over the base, and seemed to become established as a permanently persistent condition, but one free from cardiac irritation. In this state the patient was daily progressing to recovery, when a case of extremely low maculated typhus was placed in the next bed to him.

The striking character of this case, attended with much delirium, made a deep impression on the mind of the patient, all but convalescent from his rheumatic attack, and he glided, by insensible gradations, into the typhic state, soon presenting a well-marked eruption of true typhus rash; muscular debility ensued, and the patient's state was soon undistinguishable from that of the ordinary typhus inmates of the ward. The pulse rose slightly above 100 per minute, and became weak, soft, and compressible; but the most noted change was that manifested in the heart. This organ was daily examined with great care. When the patient lapsed into typhus the cardiac action was attended by a full and well-marked systolic murmur, audible at the base, propagated up the aorta, but heard over the left side likewise. Day by day, as the state of typhus fever progressed, the cardiac impulse and systolic sound became more and more feeble, until finally all trace of murmur disappeared.

A day or two subsequently, the force of the impulse was still further reduced, and the integrity of the first sound became more and more impaired, until finally, the *tic-tac* action was assumed, and the first and second sounds were of the same duration. In further evidence of the full sway which the typhic action acquired over the patient's system, it may be mentioned that though in a well-ventilated ward, and in a sheltered position in it, he developed a marked amount of secondary typhoid bronchitis, which, for a few days, raised anxiety as to the issue of the case.

The complete extinction, or extrusion as it were, of all remains of the rheumatic element of this case on the accession of the typhic influence, is worthy of comment. The patient gradually convalesced; the heart daily reacquired vigour of impulse, and full integrity of its first sound, but all trace of murmur was finally extinguished, and although,

owing to the protracted debility, consequent on two so closely consecutive and formidable maladies, the patient was kept an unusually long time in hospital, no attempt to re-establish murmur was ever noticeable. The patient, who was much dispirited on finding that when he was convalescing from one malady he had contracted another, of which he evidently entertained far more serious apprehensions (no uncommon thing, though all considered, the comparative gravity of the maladies is not a matter so easily to be determined), was much comforted on being assured that the second affection seemed to have expelled the remaining ill effects of the first.

Case 3.—The patient, a man, aged 30, was admitted into the Whitworth Hospital, with fully developed rheumatic arthritis in all the joints. He was placed on the plan of treatment already referred to. On about the fourth or fifth day, slight but distinct systolic murmurs was observable in the cardiac region. A few leeches were applied, and in a brief period the murmur alluded to gradually subsided, and finally disappeared altogether. The patient convalesced finally.

Viewed in connexion with other instances which have fallen under his experience, Dr. Lyons observes that these cases go to establish a basis of evidence on which it is fairly assumable—

1st. That under certain circumstances, endocardial murmurs occurring in the course of rheumatic arthritis, and therefore presumably of organic origin, may disappear in the sequel of the case under treatment.

2nd. That by reason of a modified state of system, induced by another disease, as that of typhus fever supervening on rheumatic arthritis, a cardiac murmur of presumably organic nature may finally disappear.

3rd. That as it is well-established that the intensity of a murmur is no measure of the gravity of the valvular lesion, the persistence of even marked endocardial murmur in the sequel of rheumatic arthritis does not necessarily indicate incurable valvular disease.

4th. That it is highly expedient that all proper measures should be directed to promote the removal by liquefaction or absorption of bead-like deposit, or incipient warty vegetations upon the valves; and that so far as is practicable, rest to the heart from all unnecessary exertion and excitement should be enjoined.

In the three cases just cited the flannel vest was employed, the sheets were removed, and all precautions were adopted which could ensure a uniform and equable temperature around the patient, with the least possible risk of exposure to cold. Farinaceous diet with milk was enjoined, and all stimulants were withheld. The relief to the intense pain in the articulation was great and permanent from the use of the poultices described above.

~~~~~

OUTBREAK OF CHOLERA IN THE WEST RIDING.—Much alarm has been caused in Batley and Dewsbury, West Yorkshire, on account of the occurrence of several fatal cases of Asiatic cholera. On Tuesday week a man living in Batley was suddenly seized with racking pains in the abdomen, and in a short time all the symptoms of cholera presented themselves in a virulent form. The surgeon who was sent for applied various remedies, but without effect, and the unfortunate sufferer expired at noon on the same day. The attack proved fatal in under six hours. The deceased resided in a locality notorious for its dirty, overcrowded hovels, and for the number of filthy heaps which are allowed to accumulate in the most exposed parts. The local authorities are aware of the invasion of cholera in the town, but as yet no precautionary measures have been taken. A few days ago a lady in Dewsbury, whose dwelling stands in a neglected part of the borough, fell sick and grew worse. Her medical attendant soon discovered that she was suffering from cholera, and treated her accordingly, but she died within 48 hours from the commencement of the attack. Diarrhoea of the severe type is very prevalent in the district, and fears are entertained that this is but the precursor of cholera on an extensive scale.

## Proceedings of Societies.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JUNE 6TH, 1866.

Dr. BARNES, President.

THE following gentlemen were elected Fellows of the Society:—Dr. F. Boulton; Dr. R. C. Croft; Dr. Maddever, Rothsay; Dr. Tannahill, Glasgow; Dr. Yeaman, Glasgow; Mr. A. G. Chattaway, Leominster; Mr. A. L. Peacock, Devonshire.

Dr. GREENHALGH exhibited several specimens of Medicated Cotton Wool which had been recently made at his suggestion by Messrs. Bell and Co., of Oxford-street. He used them chiefly for application to the neck of the uterus and vagina. Being prepared with glycerine, they could be used much stronger and applied for a longer period, and are much cleaner than the greasy pessaries and suppositories in ordinary use. The specimens exhibited consisted of—

|                                               |                   |
|-----------------------------------------------|-------------------|
| Cotton wool with iodine and iodide of potass. |                   |
| " "                                           | atropine.         |
| " "                                           | morphia.          |
| " "                                           | iron and morphia. |
| " "                                           | tannin.           |
| " "                                           | matico.           |

He had pursued the following mode of application:—A portion, about the size of a half-crown piece, secured by a piece of thread, is applied through the speculum to the affected part, over which a larger piece of cotton wool, similarly secured and freely saturated in glycerine, is to be placed, and retained *in situ* from twelve to twenty-four hours, when it can be withdrawn by the threads either by the patient or practitioner.

Dr. WYNN WILLIAMS exhibited a specimen of a large Abdominal Cyst, which he had removed from an unmarried female, 40 years of age. The case had been supposed to be one of ovarian disease, and a month previous to the operation seventeen quarts of fluid had been withdrawn by tapping. Death unfortunately took place twenty-four hours after the removal of the mass; and a post-mortem examination showed that the tumour had no pedicle, and was unconnected with the uterus or its appendages.—The specimen being of an exceedingly interesting nature, it was referred to a committee for further investigation and a report thereon.

Dr. SANSON exhibited a Uterine and Vaginal Douche.

Dr. GRAILY HEWITT exhibited a specimen of Uterus during Menstruation; also a coloured drawing of the specimen while in a recent state. The specimen exhibited very perfectly the condition of the uterus during menstruation. One ovary contained a Graafian follicle quite recently ruptured. The subject of the case was a girl, aged 15, who died forty-eight hours after being severely burnt.

Dr. J. BRAXTON HICKS exhibited some Sticks of Anhydrous Sulphate of Zinc, which he recommended to the notice of the Society, having himself found them very useful and safe in the treatment of those conditions of the canal of the cervix uteri requiring styptics: such as produced cervical leucorrhœa, menorrhagia, &c. He considered that they were much more efficacious than fluid injections, because the stick could be allowed to remain in the canal, whereby a much more prolonged contact was obtained. They were made for him by Johnson and Sons, Basinghall-street, City.

Dr. GRAILY HEWITT read a paper on

#### MENSTRUATION IN PREGNANCY.

The following case was related illustrative of the occurrence of menstruation in pregnancy, and as a contribution

to the knowledge of this subject. A. B.—, aged upwards of 30. Several pregnancies previously. Last child born June 23rd, 1865; suckled one month. Catamenia Sept. 15th to 25th; in October absent; on Nov. 7th a discharge of blood, with slight watery discharge, alternating for a week. Dec. 7th, "poorly," as usual, for six days. January 8th, 1866, felt quickening. March 1st, pregnancy distinctly diagnosed. Delivery of a female child, apparently about a fortnight short of full time, on May 17th. The author considered it probable in this case that there was a twin conception, one ovum perishing and giving rise to the flooding observed in November. It might be that some other cases of apparent menstruation in pregnancy have a similar source; but in regard to the majority of the cases of menstruation in pregnancy, and excluding cases of irregular hæmorrhage, he believed the source of the blood to be the decidua vera, as in ordinary menstruations, the unusual condition in such cases being the absence of adhesion of the two membranes, the decidua vera and decidua reflexa. The decidual chamber may, in other words, persist to a later period than usual, in which case there is no difficulty in accounting for the exudation of blood from within it, and its appearance externally.

Mr. ROBERT ELLIS read a paper

#### ON ANÆSTHESIA BY MIXED VAPOURS.

In opening this subject, Mr. Ellis said it would be taken for granted that the administration of mixed anæsthetic vapours possessed certain advantages over that of pure chloroform, counteracting the depression produced by the latter agent, and giving great security to the anæsthetic art. But the difficulty consisted in the due application of these vapours, and up to this time the anæsthetic fluids had been simply mixed together, and their resulting vapours administered. It was then shown that the whole theory of anæsthetic mixtures, and especially of those recommended by the Chloroform Committee, was based on an error; this being the idea that the vapours of each fluid would rise from the mixture in the same proportions as those of its constituents. A large number of experiments were detailed, the object of which was to prove in the clearest possible manner that this notion was wrong from the commencement. Anæsthetic mixtures were shown to give off their respective constituents in vapour as nearly as possible in the order indicated by their boiling points. Thus ether came off in largest quantity, and alcohol in the least; and it was found that it was not possible to construct any formula for an anæsthetic mixture which would give off a definite and unvarying constitution of vapour from first to last. The patient consequently would be inhaling a mixture of vapours of different character at each moment of evaporation, and no reliance could thus be placed upon these compounds. The author, therefore, denounced the whole practice and theory of anæsthetic mixtures in the fluid form as uncertain in their effects, and not to be depended upon for practical employment. Mr. Ellis, however, believing in the great value of a true system of anæsthesia by mixed vapours, was led to the discovery of a simple means by which this anæsthetic method might be carried out in practice. In the instruments exhibited to the Society the following principles were completely carried out:—

1st. The anæsthetic fluids were evaporated in distinct and separate chambers, and their vapours were combined in an air-chamber on their way into the lungs.

2nd. The proportions of each vapour were regulated by a most simple mechanical contrivance.

3rd. It was impossible to give an over-dose of either ether or chloroform in consequence of the peculiar adjustment of the receptacles for those fluids.

Without entering into the details of construction of these inhalers, the author drew attention to two very important features in his invention, which he believed likely to influence for good all future form of chloroform instruments. The first of these was the method of only liberating a cer-

tain number of minims per minute of chloroform or ether. This was effected by an adaptation of the self-acting law of capillary attraction. And the other was the powerful evaporating surface of a frilled description, by which he could saturate the inspired air with the powerfully stimulant vapour of alcohol. He estimated at a high rate the value and importance of these adjustments, and invited the close attention of the meeting to their excellent performance. The fluids employed by the author were pure chloroform, ether, and alcohol; and so great was their economy of use that, in anaesthesia for such an operation as ovariectomy, extending over half an hour, scarcely two drachms of chloroform were used—an allowance of less than four minims per minute, or only *three quarters per cent.* of chloroform in the inspired air. In midwifery practice, in which the author claimed for his system many special advantages, he seldom used more than from sixty to ninety minims of chloroform per hour.

Dr. SANSON thought the observations of the author most valuable, as urging upon the attention of the profession the necessity of a proper dilution of chloroform. From his own experience he was assured that by the ordinary rough means adopted to administer chloroform it was common to allow an atmosphere of from ten to thirteen per cent. to be inspired. Dr. Sanson explained his theory of narcotism, especially the action of narcotics upon the calibre of the arteries. A typical anaesthetic would be one which would not, on the one hand, like chloroform rapidly abrogate the functions of the sympathetic and paralyze the heart, nor, on the other hand, "over-stimulate"—i.e., by contracting the arteries, throw a large volume of blood upon the venous system. Chloroform acted best when freely diluted, but, unlike the author, Dr. Sanson considered that this dilution could be effected without special apparatus. Ether was ineffectual for dilution, because, from its volatility, it nearly all evaporated away from its mixture with chloroform; and its excitant as well as nauseating properties were objectionable. But from great numbers of experiments (many of which Dr. Sanson detailed), he was convinced that in chloroform diluted with an equal bulk of absolute alcohol we have an excellent anaesthetic, which gives off a proportion of chloroform vapour in a given time almost exactly half of that which is given off by chloroform pure and simple. As to Mr. Ellis's instrument, though most ingenious, he thought, as anaesthetics were for the many and not for the few, we should recommend such a process as will render anaesthesia safe, and be encumbered as little as possible with mechanical complications.

Mr. ELLIS, in reply, stated that he could scarcely sufficiently forcibly dwell on the fact that the fluid anaesthetic mixtures gave off uncertain and varying compositions of vapour—a fact clearly demonstrated by many of the experiments he had detailed, and that, therefore, they were not to be relied upon. Especially in midwifery practice this grave error, in consequence of the duration of inhalation, was most manifested. He could by no means agree in the remarks of Dr. Sanson as to administering as high a per centage of chloroform as four per cent. He was, by his system, perfectly well able to obtain speedy, and to sustain prolonged, anaesthesia with an allowance of barely one per cent., the security and well-doing of the patient being, in his opinion, in exact proportion to the diminution of the dose of chloroform. The vapours of ether and alcohol mixed with it seemed in an extraordinary manner to enhance the activity of the chloroform, and safely to sustain its force. He begged, in conclusion, to exhibit to the Society a perfectly new form of his inhaler. This instrument he had especially designed for his use in midwifery. It was simple in construction, and of equal safety in use with the more powerful inhaler. Its principal feature was a beautiful little reservoir for chloroform, which, acting on the principle already alluded to, dropped that fluid over an evaporating surface, at any rate per cent. desired by the operator. The instrument was thus effectually protected against an overdose.

Dr. BATTYE read a paper on  
AN EXAMINATION OF CERTAIN UTERINE AFFECTIONS IN  
THEIR RELATION TO PHTHISIS PULMONALIS; WITH  
CASES.

The author's attention to this subject had extended over fourteen years, during which time he had collected numerous examples of various forms of uterine leucorrhœa coexisting with affections of the lungs. He brought eleven cases before the Society, minutely describing the symptoms and termination of each. It was shown that as soon as the leucorrhœa was cured or relieved, the chest-symptoms also either entirely disappear or lessened in extent and force. He strongly urged early special attention during the treatment of phthisis to uterine discharges when present, as such caused a constant drain on the constitution. As to treatment, he seldom used local remedies, but trusted to acids, vegetable bitters, and cod-liver oil. The salts of iron were found by him to be very valuable in the chronic forms, having a special effect on the lung condition as well as on the uterine discharge.

### NEW PHARMACEUTICAL PREPARATIONS.

#### GUFFROY'S COD-LIVER EXTRACT.

THE inventor of this preparation, which is coming into considerable use in London and elsewhere, proceeds on the hypothesis that the active medicinal principles of the Cod-liver oil are to be found in the greatest abundance in the watery constituents or serum of the liver, which he has converted by his process of sugar-coating into an attractive preparation. He claims for his Cod-liver Dragées that they contain all the beneficial ingredients of full doses of Cod-liver oil, and being of very small bulk and perfectly tasteless, they completely obviate the objections which bar the use of that agent in the cases where it is most wanted. We take our information from an explanatory pamphlet issued by the manufacturer, whose statements must stand *quantum valet*:—

"Many persons, thinking that the nausea caused by the oil, was to be attributed to the colouring and empyreumatic matters contained in the common cod-liver oil of commerce, recommended the use of refined and colourless oils; but the slight advantage which was thus obtained in rendering the oil less repulsive, was by many thought to be more than counterbalanced by a loss of remedial virtue. Others, less happily inspired, proposed to administer the oil in the form of jelly, but that also failed. It was then attempted to render the oil less unpalatable by enclosing it in gelatine capsules, but little was thereby gained, since the gelatine in no way tended to promote the retention of the oil by the stomach. Some, again, have tried to produce an artificial cod-liver oil, by imitating its chemical composition. . . . It was evident that the composition of a complex organic product like the oil in question, could not be successfully imitated by any artificial compound. But it was equally clear that whatever virtues cod-liver oil possessed over other animal oils and fats, were referable to the source from which that article was procured—namely, cod liver. . . . The inventors had noticed that the substances to which the best authorities attributed the medicinal properties of cod-liver oil—namely, gaduin, propylamine, iodides, bromides, and phosphates, were more soluble in water than in oil; and as cod-liver contains a larger proportion of water than oil, they formed the opinion that the watery components of the livers must carry off the greater part of those substances. Chemical analysis, followed by practical observations, fully confirmed these theoretical views. It has been distinctly proved that the oil contains but a very small part of the medicinal elements existing in cod liver, and that the greater portion is left in solution in the waters which have hitherto been thrown away.

"This important discovery once made, it only remained to reduce the watery constituents of the livers to a proper official form, in order to possess a medicine containing the active principles of cod liver, separate from the oil. That of extract was adopted as the most suitable. The waters were

accordingly evaporated, and were found to yield a product which, on being analyzed by Dr. Garreau, Professor of Chemistry in the University of Lille, proved to have the following important chemical constitution:—

|                                             |         |
|---------------------------------------------|---------|
| Ichthyoglycine . . . . .                    | 50·000  |
| Propylamine . . . . .                       | 2·545   |
| Acetic, lactic, and butyric acids . . . . . | 6·000   |
| Phosphoric acid . . . . .                   | 2·090   |
| Sulphuric acid . . . . .                    | 0·200   |
| Chlorine . . . . .                          | 1·525   |
| Iodine . . . . .                            | 0·154   |
| Bromine . . . . .                           | trace.  |
| Soda . . . . .                              | 1·170   |
| Potash . . . . .                            | 0·211   |
| Magnesia . . . . .                          | 0·366   |
| Lime . . . . .                              | 0·510   |
| Ammonia . . . . .                           | 2·862   |
| Extractive matter undetermined, gaduin, &c. | 10·620  |
| Water and loss . . . . .                    | 21·747  |
|                                             | 100·000 |

“The extract thus obtained presented, however, two difficulties: in the first place, it was found to be exceedingly deliquescent, and, secondly, it was too concentrated for direct administration. These obstacles were overcome by mixing intimately with the extract about an equal weight of cacao-butter. The resulting compound was a firm and stable mass, of which pills, capable of being sugar-coated, could be made. By these means the preparation assumed the form of sugar-plums or *Dragées*.

“A proper official form for administering the new medicine having been found, it was submitted to the Académie Impériale de Médecine of Paris, who, in the month of May, 1861, appointed a committee, composed of Drs. Bouillaud, Poggiale, and Devergie, to examine, experiment, and report upon it.

“At the meeting of the 21st October, 1862, the Académie approved and adopted the report of those gentlemen. It will thus be seen that the deliberations of the committee extended over a period of sixteen months—a length of time which afforded ample opportunity for prolonged trials and a well considered decision.

“This report, which is too lengthy to be here given *extenso*, recognizes the accuracy of the analysis of Dr. Garreau of Lille, and deduces from it a comparison of the proportion of chemical elements contained in the extract, with that found in oil of the best quality. According to this comparison, cod-liver oil contains scarcely 3-1000th of the elements iodine, sulphur, chlorine, and phosphorus, while the extract possesses 98-1000th of the same elements, or their acids, thus showing thirty-three times the amount; and while, from the oil only, about 10-1000th extractive matter can be obtained, cod-liver extract yields 724-1000th, or seventy-four times more.

“If, continues the report, ‘chemical composition be taken as the measure of the comparative value of cod-liver oil and cod liver extract, it must be admitted that twenty centigrammes represent nearly forty-five grammes of oil, or more than two tablespoonfuls. . . . The extract obtained from cod livers contains, in a condensed form, all the active therapeutical principles of cod-liver oil. . . . The system under its use acquires more vigour, the appetite gradually returns, the complexion improves, and the muscular strength increases. In short, the administration of the extract, like that of the oil, promotes assimilation, and consequently tends to the improvement of the general health of the patient. The richness of its chemical composition, its efficiency and certainty of action on the economy, the possibility of administering it to the most delicate and fastidious persons, constitute it a valuable therapeutical agent in all those affections which require the employment of cod-liver oil.’

“Cod-liver extract has likewise been tried in Russia, under the auspices of Dr. Kalenitchenko, Professor of Medicine in the University of Karkow; and has been officially recognized and authorized by the Imperial Medical Council of St. Petersburg.”

The course adopted by the patentee of this preparation is such as to merit, *ab initio*, the confidence of the profession. He has not desired or attempted—as others have done—to force the medicine amongst the general public, but has

simply submitted it to the profession on its own merits. He expresses a hope that medical men will be induced to give it a fair trial; if they find it meet their expectations, prescribe it regularly; if not, reject it summarily.

With reference to its employment in practice, he says:—

“Possessing, perhaps, in a higher degree than cod-liver oil itself the peculiar remedial properties of that substance, it is well qualified to take its place in certain cases even when the oil can be borne. But irrespectively of its claims in this respect, the full value of which enlarged experience can alone determine, cod-liver extract specially recommends itself in the following circumstances:—

“1—When the oil is rejected by the stomach.

“2—When, although the oil is not actually refused by the stomach, the production of nausea and disgust, renders a change of remedies very desirable.

“3—When, without discontinuing the oil, there may be reason for wishing to increase its efficacy.

“4—When the oil, whether agreeing or not with the patient’s stomach, has failed to produce beneficial results.

“These objects may, according to circumstances, be attained by prescribing the extract alone, by administering it along with some oily matter less nauseating than cod-liver oil, by alternating its administration with that of the oil, or by giving it at the same time with the oil, and thus, as it were, enriching the latter substance with a superadded dose of those more active principles, in which cod-liver oil is deficient.”

We will not be expected to give an authoritative opinion here as to its merits. Theoretically it is simply a question of what the benefit derived may be due to. If it be simply the oil itself, it appears rather inconsistent to prescribe cod-liver instead of many less nauseating oils. If it be the Iodine, Ichthyoglycine, Propylamine, or other correlative ingredients, the inventor has, we think, proved his case.

We are not certain that Mr. Guffroy has been judicious in labouring so energetically to make the medicine pleasant to the taste, for the profession in Great Britain seem to look coldly on the *Dragées* and *Troches* of the French Pharmacy. If it is any inducement, we may say that the cod-liver extract, before it has received the coating of sugar, is as unpleasantly fragrant a preparation as could be desired.

### CHOLERA HOSPITALS.

A REPORT on Cholera Hospitals has been drawn up by the Council of the Epidemiological Society, of unusual interest at the present crisis, and will immediately issue from the press. In March, the Council, having regard to the threatened outbreak of cholera, drew up a series of queries referring (1) to the advisability or not of cholera patients being admitted into the general wards of hospitals; (2) to their admission into special wards set apart for them in hospitals; and (3) to the necessity of special hospitals for the treatment of such cases. These queries were distributed amongst the most eminent members of the profession, and a series of replies of great value have been received. Amongst those who have expressed opinions in answer to the queries may be enumerated the Presidents of the Royal College of Physicians and of the General Medical Council, the Director-Generals of the Army and Navy Medical Departments, the Physician to the Secretary of State for India in Council, Dr. Jenner, F.R.S., Dr. Milroy, Professors Laycock, Parkes, Maclean, Gairdner, Sir D. J. Corrigan, and numerous other distinguished men. The following is the substance of the report:—

I. There appears to be a general concurrence of opinion, expressed or implied, that under certain circumstances and conditions cholera is liable to be communicated from person to person; the liability being usually in proportion to the crowding of many persons together, the defective ventilation of apartments, and the neglect of thorough cleanliness in respect of person or abode.

In addition to the possible risk of the extension of the disease from this source, the alarming character of the symptoms, and the necessity for unremitting attendance

upon the sufferers, are calculated to produce terror in the minds of spectators, and thus strongly predispose them to be attacked during an epidemic season.

For these reasons the opinion is very generally held that it is unadvisable that cholera patients should be admitted into wards which are occupied by other sick inmates.

The experience, however, of some of the metropolitan hospitals in past epidemics shows that, due attention being paid to sanitary arrangements, cholera patients may be received, in limited numbers, into the general wards without injurious results either to the other sick or to the ordinary attendants.

No instances have been referred to, in the evidence before the Council, in the opposite direction—viz., of the disease having spread to the other inmates of a ward in a well-regulated hospital.

II. With respect to the second query, the experience of the metropolitan physicians who have favoured the Council with replies appear to be that, with proper precautions, cholera patients may be admitted into separate wards in general hospitals or infirmaries without undue risk of the extension of the malady to the other inmates of the institution.

This opinion is shared by all the respondents who have had experience of the disease in tropical countries.

It would have been very desirable to have been informed of the results on this point in some of the military and naval hospitals in this country and also abroad.

The precautions above referred to are these:—(a) Ample space to each patient; not less than 1500 or 2000 cubic feet. (b) Thorough ventilation of the wards at all times both night and day. (c) Immediate disinfection, and removal of the excreta, soiled linen, &c. (d) A separate staff of nurses.

III. The reply to the third query depends much on the opinion formed in respect of the two former questions. If cholera patients are not admissible into general hospitals or infirmaries under any condition, it is obvious that some extemporised and special arrangements must be provided for the reception of the destitute when attacked.

But even when they are admitted, there are various circumstances in which it will be advisable or necessary that special hospitals should be provided, *e.g.*—(a) When general hospitals or infirmaries are at a distance from the seat of the actual or apprehended outbreak. (b) When there is a want of accommodation, with due regard to the ordinary patients, or when the accommodation is unsuitable or objectionable.

In selecting the site of special hospitals, the following points require to be attended to:—(a) Nearness, if possible, to the chief seat or seats of the outbreak. It is important that cholera patients should not have to be carried far. There is, moreover, great risk in moving patients in, or verging to, the state of collapse. (b) Airiness, and freedom from intrinsic or contiguous sources of atmospheric pollution. (c) A dry soil and raised situation are, of course, to be always preferred to a low and damp one.

Amid the crowded districts of a large town, it appears preferable that several small and suitable hospitals, or "houses of recovery," should, if possible, be established in different localities, rather than one or two large hospitals for the reception of a great number of cholera patients.

The remark that the presence of an experienced staff of medical officers in general hospitals, and the existence of more complete appliances of every sort in them than is likely to be provided in extemporised special hospitals for the treatment of cholera patients, are marked advantages in favour of the former, deserves consideration.

The general conclusions of the Council are these:—

1. That it is, on the whole, unadvisable that cholera patients be admitted into the ordinary wards of general hospitals or infirmaries.

2. That cholera patients can be safely admitted into special wards in general hospitals, due precautions being taken; and therefore that it is desirable, as an important means of providing accommodation for the destitute

when attacked, that the authorities of these institutions grant this valuable benefit to the public.

3. That it will be often necessary that special hospitals be provided in aid or in lieu of general hospitals and infirmaries.

In addition to these arrangements for the accommodation of the poor when attacked with cholera, the Council would recommend that places of refuge be provided for the temporary sojourn of some of the unattacked inmates of unwholesome dwellings and localities where the disease has appeared.—*Lancet*.

## London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 25, 1866.

### THE WORKHOUSE INFIRMARY OF ST. MARY, ISLINGTON.

In the report just published by Mr. FARNALL on the Metropolitan Workhouses, he specifies certain establishments which he condemns as unfit for the reception of the sick, and incapable of being satisfactorily adapted for that purpose. These are Clerkenwell, St. Giles's and St. George's (Bloomsbury), Holborn, St. Margaret's and St. John's (Westminster), St. Martin's-in-the-Fields, St. Mary's (Islington), the Strand, Whitechapel, Bermondsey, St. George-the-Martyr, and Lambeth.

Now it will be recollected that every one of these establishments has been prominently brought before the notice of the public very lately in consequence of the gross mismanagement of the departments intended for the sick; but it can hardly have escaped notice, that the sanitary condition of the workhouse of St. Mary, Islington, has been passed over somewhat lightly, and even the *Lancet* Commissioners, who have been severe enough in their animadversions on other establishments of a similar character, have been satisfied with a mild remonstrance as to the construction of the Islington building, and have even indulged in a kind of passing eulogy on the Trustees of that parish for their praiseworthy intention of building another and more suitable edifice. If any such intention has really been carried into effect, we will join in the eulogy, but considering that the Trustees have expressed this intention for the last twelve years, and that the Poor-law Board and their Inspectors have been during the whole of that time fully aware of the gross defects of the building and of the flagrant mismanagement of the sick department, we may be excused for disbelieving any professions of a wish for improvement on the part of the Trustees, until we learn from authentic sources that the new building has been erected. Twelve years, as is well known, is quite enough and more than enough time for the completion of the Thames Embankment, or of the Houses of Parliament, or of a railway of the length of Great Britain, or of any other gigantic enterprise in modern days, and surely it ought to be sufficient for the building of a Metropolitan Workhouse. In the favoured district of Islington, too, there

is no want of space for building purposes, no want of architectural skill, and no lack of means, and in a far shorter time than it has been necessary to think about building a habitation for the sick poor, there have sprung up in the same suburb whole rows of streets and squares, scores of churches and chapels, besides two huge prisons, and an immense cattle market.

Mr. FARNALL, however, may possibly believe that the defects of the Islington Infirmary were unknown to the Poor-law Board and their Inspectors, and Dr. SMITH may perhaps think that the Medical Officers were to blame in not representing to the Trustees the necessity of improvement. But if Mr. FARNALL or Dr. SMITH hold any such opinions they are entirely mistaken, for the Trustees and the Poor-law Board were all made thoroughly acquainted with the condition of the building, the ill treatment of the sick poor, the overcrowding of the wretched inmates, the want of classification, the absence of proper nurses, and all the other abuses which have lately been exposed in other institutions of a similar kind. The Poor-law Inspectors actually visited the Infirmary on repeated occasions, Mr. H. B. CANE being one of them, and they measured the cubic space of air accorded to each person; and yet with all this knowledge, the Poor-law Board positively refused even an inquiry into the state of the Workhouse, and contented themselves with receiving an assurance on the part of the Trustees that the latter intended to build a new establishment.

We propose, for the edification of philanthropists and for the refreshment of the memory of the Poor-law Board, to publish some details of the condition of the sick in the Islington Workhouse, as it was reported to and witnessed by the Poor-law Inspectors twelve years ago, and we can only add at present that unless it can be proved that substantial reforms have been made since that period, the Poor-law Board are convicted, in this instance at least, of a gross dereliction of the duty which has been imposed upon them by the State, and which they are liberally paid to discharge.

#### THE LOTHIAN'S MEDICAL ASSOCIATION.

IN another part of our columns we give a full report of a large and influential meeting of medical men, both from town and country, held in Edinburgh on Wednesday last, at which the Lothians' Medical Association was fairly started into existence. It is, we may remark, neither the first nor the only one of its kind, but, being composed of the practitioners in the metropolitan counties, it promises to be by far the most influential medico-ethical society ever instituted—in Scotland at least—and by means of subsidiary affiliated societies it may become a most useful means of promoting unity among the members of the profession, as well as a most powerful agent in bringing the united opinion of the profession to bear upon Government in regard to legislation involving its interests, a matter which, to their own loss, has been too much neglected by the vast body of medical

practitioners, and in regard to which our two Colleges—of Physicians and Surgeons—who have hitherto fought the battles of the profession, will find their hands immeasurably strengthened by the co-operation of this subsidiary College of General Practitioners, for such this Lothians' Medical Association, if properly carried out, promises in truth to be. The draft of the constitution of this Association, as brought forward at the meeting and embodied in our report, is in some respects scarcely consistent with the dignity of the profession, and will no doubt be importantly modified before being finally accepted. It would be a decided lowering of the profession to embody an association for the purpose of telling the public that midwifery fees are to be paid at the time, or that messages ought to be sent early; these are matters for private arrangement, the first of which is easily settled, while the chief difficulty in way of settling the latter is the amount of competition present and the way in which that competition is carried on. Wherever the public find half a dozen medical men ready to run after them at a moment's notice there are plenty amongst them who prefer to consult their own convenience in sending; where the choice is more limited and discriminating they consult that of the medical men. On the other hand, the very great importance of there being something like a standard table of fees, by which the pecuniary relations between the public and the profession could be regulated, has quite recently received additional illustration in the dispute between the Warden of Trinity College, Elenalmond, and Mr. MAUGHAN, his medical attendant. Not to enter too minutely into this dispute, we may merely mention that the Warden, Dr. HANNA, though not objecting to 5s. as a reasonable fee, yet objects to pay it for every visit; nominally he acknowledges five shillings quite reasonable, really he wishes to pay only half a crown or less, and he asserts that his former medical attendant in Edinburgh never charged him for every visit, while his consulting physician received his fee of one guinea only on alternate visits. Now we have no hesitation in saying that if Dr. HANNA's former professional advisers did act thus—in the absence of any special reasons—they acted unprofessionally, and undersold their brethren, a matter which perhaps seemed to them of little consequence at the time, but which we now find to have been fraught with results which tend to affect more or less the relations with the public of every man in the profession. Surely, however, these men have something to say in their own behalf; their names cannot long remain unknown; let us not condemn them unheard. In regard to medical attendance, many men choose to protect themselves against what they imagine to be a too great multiplication of medical visits, by paying their professional attendant an annual sum. This we conceive to be the most advantageous mode for all parties, inasmuch as it will induce the very worst doctor to cure his patient as quickly as possible, and will prevent him profiting by his very unskilful-

ness, which otherwise he is permitted to do; while the best doctor of course gets off with the easiest work, and are not mulcted of half their income, because they are skilful, as they now too often are. For general practice, we contend, a regular annual payment of a fixed sum is the best for all parties. In India this is the rule, and we should like it introduced here; then, in Bengal at least, one week's pay is considered a very reasonable allowance. We should think it would be the same here, and that few of us would quarrel with our income, though restricted to only one week's pay from each of our patients.

### THE CHOLERA.

OUR readers will learn with regret that the appalling epidemic has been introduced into this city from Liverpool, and that three cases have already occurred in the same room in a house on City-quay, two having proved fatal in fifteen hours each. The first patient, a girl aged 15, was landed from one of the Dublin and Liverpool steamers on Thursday morning, having been purged and vomited during the passage. She was severely attacked at ten o'clock the same night, and died at one p.m. on Friday. Steps were at once taken by the Medical Officer of Health and the City Coroners to disinfect the house and to enforce the speedy burial of the deceased, but unfortunately there were no means for isolating or treating separately any other cases to which the contagion might spread. Exhortation to prevent waking and the presence in the room of several persons not required for the care of the sick has proved useless. On Monday, at seven o'clock a.m., the niece of the deceased, a child of three years of age, was attacked, and died at about twelve the same night. The father, while returning from the coffin-maker at four a.m. this morning (Tuesday), took ill in the street, and as we write suffers from the unmistakable symptoms of the epidemic. All the cases have been actively treated by Dr. Shanahan (Count de Kavanagh). The house, 3, Upper Frederick-st., in which the girl resided at Liverpool, is a greatly overcrowded lodging-house, frequented by foreign sailors, and a case of cholera occurred in the same street on Wednesday last, but was at once removed to the wards at the workhouse, Brownlow Hill. About 80 patients have been up to the present treated in these wards, and every plan has been fairly tried. Amongst those which are somewhat novel, have been the subcutaneous injection of morphia, of strychnia, and of hydrocyanic acid, the administration of camphor in large doses, and the application of ice to the spine, either constantly or alternately, with hot water, all of which have proved miserably unsuccessful. The last few cases have been treated on the plan recommended in Dr. George Johnson's most persuasive book, "Notes on Cholera," with results very satisfactory. The able resident attendant, Dr. J. W. McCloy, formerly of the Belfast Hospital, will publish the cases shortly in a complete form. He administers castor-oil in about ounce doses in every stage of the disease; tincture of henbane being sometimes added. The dose is usually retained, and reproduces purgine if this has ceased. Every physician must be convinced of the efficacy of this drug in cases of diarrhœa due to scybala or other irritants in the alimentary canal. The injection by the rectum of water at 120°, in which common salt and carbonate of soda are dissolved, is also used as

part of the "eliminative" treatment, and the free use of external warmth is also enjoined. The inmates of this vast workhouse, which number over 3000, are daily marshalled, and if any diarrhœa is discovered it is treated by castor-oil. Startling as this mode of treatment is, and contrary to preconceived notions, it demands at least careful consideration, as it has been zealously urged by one of the greatest pathologists of the day, and has already gained able adherents. To determine such points, and as the subject is nearly as obscure and at least as important as the cattle plague, a "Cholera Commission" has been advised, and in this city a conference of our leading physicians seems very desirable before advice is freely circulated amongst the poor. The type of the disease in Liverpool has been very varied, the most constant circumstance being that the loss of fluid by the stomach and bowels is in inverse ratio to the blueness of skin and decrease of circulation and respiration. Some cases have been witnessed in which the symptoms were identical with those of the cases which were described in Dublin during the early months of this summer as "Black Death," and with the true "Cholera algide" of Dr. Parkes and other writers of Indian experience.

Nearly all the cases have been brought from the Irish district which lies between Scotland and Vauxhall-roads and which for filth, vice, overcrowding, and, above all, unwholesomeness of construction, excels the purlieus of any other city. Dr. Trench, the Medical Officer of Health, has been indefatigable in efforts to improve this district, but for the unaided blind courts demolition is the only remedy. It is gratifying to reflect that the Building Acts will prevent the increase of this evil in English and Scotch cities, but in Ireland there is no controlling power with respect to the erection of buildings, however unsanitary. Every street and sewer in Liverpool is flushed with water containing carbolic acid, but other disinfectants, such as Condy's fluid, chlorine, and sulphurous acid, are used about the cholera wards.

The ovens at the workhouse for drying clothes are most admirably constructed for disinfecting purposes and the destruction of vermin, as the temperature can be raised to 300° without destroying the fabrics. They were constructed by Messrs. Tessiman and Kessick of Liverpool. Dr. Trench has also established in Ford-street a disinfection chamber, in which the temperature is raised by steam circulating in metal pipes. The clothes and bedding of the surrounding poor persons are here gratuitously cleansed and disinfected after contagious disease. Another most benevolent institution is the Bankhall Refuge, in which the friends of a cholera patient are sheltered after he has been removed to the wards or to the sheds which have been recently erected in various parts of the town. Several dispensaries, to be open day and night, and a system of house-to-house visitation, have been also organized by Dr. Gee under the Disease Prevention Act, and qualified practitioners have been advertised for at a high rate of remuneration.

E. D. M.

EFFECTS OF CIVILIZATION UPON THE FLORAL KINGDOM.—The Flora of the State of Pennsylvania is found to have undergone remarkable changes, plants that were formerly rare being now quite abundant. This effect is attributed to the spread of railways, and the change is so marked that some botanists think the "foreign" Flora will supplant the native. The valley of the Susquehanna has already been taken possession of by the invaders.

## NOTES OF LONDON PRACTICE.

DR. BISHOP, who has given a large attention to aural diseases, regrets that the late Mr. Toynbee did not use or adopt a graduated small syringe attached to a small elastic force pump for his chloroform rather than the now obsolete Clover apparatus, thus avoiding the lungs; an apparatus, we believe, which has had considerable success in the hands of Dr. Yearsley and Dr. Bishop. This "middle passage" of the ear, however, is not easily reached; and it is well known poor Toynbee did not put a very extensive faith in reaching the Eustachian tube except by vapour from the pharynx. The vapour of chloroform can thus be forced through the ear as many men can force tobacco smoke through the ear under some conditions.

As the *cattle plague* is still a vexed question in Ireland, it may be well to note its latest progress in England. The returns up to the end of July show a slight recon-  
descence or increase from 313 to 352 cases. It is very instructive and curious that twenty-two counties have been all along free of the disease, notably the six counties of South Wales (over against Ireland) and some of the Scotch Highlands, such as Argyll, Bute, Banff, Elgin, Nairn, Cromarty, as also the wilder Orkney and Shetland Isles; not that there are not cattle in these places (sheep in myriads), but that the horned cattle are not crowded together, as in the dairy and cheese districts of Gloucestershire, &c. Of the aggregate cattle of England only five per cent. in all have yet been attacked, but of every 100 so attacked 86 have died. The "crude speculation," as Mr. Simon of the Privy Council terms it, as to its being small-pox and vaccination, a cure, so eagerly adopted, has entirely died out, and with such eager errors nearly all faith in medical treatment. It is now decided that under some conditions the rinderpest also attacks sheep, as also that it affects cattle *more than once* in life, and so is not like small-pox or other exanthemata. An eruption about the vagina of the cow and increased heat of the skin are now looked on as the first indications of the disease; the recent legislative measures (opposed even by our first thinkers, like J. Stuart Mill), and a three-farthing rate for compensation, have served to keep the plague in check; the laws and logarithms of Dr. Favre notwithstanding; the disease, in fact, is still as virulent as ever, but is at once "stamped out" when it appears.

Dr. Russell Reynolds, in his new work "On Medicine," as the matured opinion of the best medical men in Europe, attacks with some vigour and no little quaintness the "change-of-type" in disease theory upheld by Stokes and others. As Claude Bernard, and Liebig, and others, go out of their way to show up the errors of the Baconian school of induction in English physic, and what it leads to in the form of hasty generalisations, as to castor-oil in cholera, vaccination in rinderpest, causes of death from chloroform in fatty heart, &c., all hasty conclusions and errors, so Dr. Reynolds would lead us to think that it is against the natural history of a disease that it should change its type when other causes in the cure are so much more efficient, such as the undoubted value of wine and stimulants in the hands of Skey or Hughes Bennett, or Clarke, our knowledge that pneumonia is not strictly an inflammation at all.

Like Mr. Erichsen's excellent monograph, however, on railway accidents, with his fourteen cases of such injuries, or some remarkable notes by Dr.

Forbes Winslow in the journals of the week on the exact condition of the brain in insanity cases, we have no doubt much conflict of opinion has arisen on this change of type question. Dr. Watson perhaps, we may say, does not believe in it.

Other talk of the week has been of Dr. Edward Smith's report, long expected but welcome, on London Workhouse Infirmarys, in which he differs widely from the late sensational reports on these institutions, the Government inclining rather to his views; but, like the debates on the Supplementary Charter to the Queen's University in Ireland, much vexed and vexing, involving, as they might or do, the teaching of anatomy or surgery only by one church or council, we may safely leave it to future decisions of the "powers that be." Perhaps a more practical point has been decided by the new Chancellor of the Exchequer, that in the next estimates the Irish workhouses shall be relieved of the rate for payment of the medical officers and schools, but the work is only half done if the salaries be not raised, as ably advocated in THE PRESS AND CIRCULAR.

Much agitation on cholera exists in London, but let us hope a little of it is sensational. Dr. George Johnson has had the curious felicity of enlisting the public anxiety deeply as to whether, in cholera, there is spasm, and whether castor oil is a cure. Mr. Simon, adopting the theories of Pettenkofer, has also in the *Times* this week startled the public by adopting the views now generally held of the infectiousness of the disease. Something like twenty cases of a mild type have been seen at the London Hospital, and five deaths. Two cases have been received at St. Bartholomew's; but at this season every year bad choleraic diarrhœa is not uncommon in these and other hospitals. Our own experience of several hundred cases of cholera in former years in London is to the effect that the diarrhœa is almost never checked in time, as MacCormac of Belfast would check it, the "chemist" prescribing some dismal mixture, which rather aggravates it.

## Medical Obituary Notices.

THOMAS ANSELL, M.D., F.L.S.

AMONG the earliest victims to the mysterious epidemic which has again visited our metropolis, we regret to record the name of Thomas Ansell of Bow, who, among other professional appointments, held that of Medical Officer of Health to the District of Bow, and who was actively engaged in devising the best methods of obviating or averting the threatened pestilence, when he was himself struck down by the shaft of the malignant but invisible foe. Only a few days since, Dr. Ansell was in the midst of his business avocations and in his usual social intercourse with his brother practitioners, and in a few short hours he sunk under an attack of cholera, which, as is now too well known, is prevailing in the eastern suburbs of London, where Dr. Ansell has long resided, and where he enjoyed a very extensive practice and the esteem and regard of a wide circle.

Dr. Ansell was born in or about the year 1798, and had experienced in his early life, and indeed even in mature years, several vicissitudes of fortune, although at last the blind goddess seemed to smile upon him, and he was in the enjoyment of an ample income as well as of "honour,

love, obedience, troops of friends," when his sudden decease plunged his own family and a large sphere of professional and general acquaintance into the deepest sorrow for his loss. For although he had arrived at a period of life when old age may be fairly said to have commenced, he was yet so genial in his manners and so cheerful and active in his habits and disposition that he had nothing of the old man about him, and he gave promise of living to an advanced period.

In his early youth he made a voyage to the East Indies chiefly for the purpose of seeing the world, and his medical education was gained at the Middlesex Hospital. He married, in the first instance, a lady who possessed considerable property in the West Indies; but in consequence of the depreciation in the value of the possessions in this region of the globe, he not only lost all the advantage he might have expected from so apparently fortunate an alliance, but his own income suffered from the necessity of keeping up the West India estates, and he was too glad at last to secure his own immunity from further pecuniary calls by the abandonment of his Transatlantic property. He survived this lady, by whom he had a family of a son and three daughters, and he subsequently married again, the second partner of his choice being in every way suited to supply the vacancy thus left in his domestic hearth.

Dr. Ansell, as we have before remarked, was engaged in extensive practice at Bow, where he was held in universal esteem. He took a warm interest in the Apothecaries' Society of London, and at the time of his death he occupied the honourable post of Chairman of the Court of Examiners of that body. He was on the point of relinquishing this position, having been summoned to take his place as a member of the Court of Assistants of the same Corporation, the offices of member of the Court of Assistants, and Member of the Court of Examiners being incompatible according to the rules of the Society.

Dr. Ansell published nothing, and did not write in the medical journals or take part in the discussions of the Medical Societies. He belonged to the class of practitioners who are too much engaged in practice to care about recording their experience, and thus whatever knowledge he may have gained in his professional career, necessarily dies with him. But he was by no means an ignorant or uncultivated man; on the contrary, he was a good classical scholar, and was well acquainted with English literature and poetry; and being a diligent reader and keen observer, he kept himself quite on a level with the scientific progress of the age. He was particularly well acquainted with botany and other branches of natural history, and was an excellent and practical microscopist. He was also a fluent speaker, and never hesitated to advocate, both in private and public, the claims of the general practitioner to the esteem and confidence of the community.

Thus far we have written of the general life and character of Thomas Ansell; but a line must be drawn between the duties of the biographer and those of the friend, and the cold expressions of esteem necessarily employed by the former melt into sorrow, deep and heartfelt, when the writer of this brief obituary feels that he has lost much more than a friend, and almost a brother. Many more will mourn the loss of Dr. Ansell in the same spirit, and will echo the sentiment now expressed, that a more genial

and kindly soul never breathed than he who has just departed in so sudden a manner, and who, like a good soldier, has fallen at his post of duty.

◆

JOHN CROWN AGNIS, M.B., F.R.C.S.,  
ASSISTANT-SURGEON ROYAL HORSE GUARDS.

Mr. JOHN CROWN AGNIS was the representative of an ancient Cambridgeshire family. Dying unmarried, he was the last of his name and race. As a lad he gave promise of great ability. When sixteen years of age he entered at University College, London, as a student on the arts side, and soon distinguished himself by carrying off the senior Greek prize, being a mere boy in comparison with his competitors. He subsequently commenced his medical education at the same school, and, throughout a successful student career, developed in a high degree qualities of mind and heart which led his compeers to anticipate for him a bright future, and drew to him very many friends, whose loving fellowship continued to the end of his life. He became house-surgeon of the hospital, graduated as M.B. at the London University, and subsequently passed the fellowship examination of the College of Surgeons. Those who knew his great abilities were somewhat disappointed that he elected to enter life as an army surgeon. He was gazetted to the 3rd Light Dragoons, and afterwards became assistant-surgeon to the Horse Guards Blue. He held this post until his death on June 28th, in the 38th year of his age.

A severe chill was followed by rheumatic meningeal inflammation, which terminated in serous effusion. This last illness was brief, but his general health had been previously impaired by a severe accident whilst hunting.

He was a bold and skilful operator, notably endowed with that special surgical acumen which is logic in action. Some while before his untimely death he had taken into consideration the cogent solicitations of many friends desirous that his great abilities should be more widely appreciated, and had directed his attention to the subject of deformities, and energetically followed out a series of special researches into their general surgical pathology. When the Jacksonian prize for an essay on Clubfoot was awarded to Mr. Adams in 1864, the treatise of Mr. Agnis was considered so meritorious that an extra honorarium was adjudged in recognition of its special merits. The paper was accompanied by numerous illustrations drawn by the author; for Mr. Agnis, in addition to many other accomplishments, was a skilful artist. He was an enthusiastic entomologist, and versed in almost every branch of natural science. His death is deeply felt by a large circle of friends, and of these were all who knew him.—*Lancet*.

---

SEAMAN'S HOSPITAL SOCIETY.—A quarterly general court of the governors of this corporation was held on Friday at the offices, King William-street, City; Sykes Thornton, Esq., in the chair. The minutes of the last court, &c., were read by the secretary and confirmed. The secretary read the half-yearly report, from which it appeared that the numbers of patients admitted from the 1st of April to the 30th of June were as follows:—From her Majesty's ships, 2; from British and foreign merchant ships, 482. On board 31st of March, 178; total 662. On board, sick, 131; convalescent, 9; fit for duty, 0; discharged since the 31st of March, 522; total, 662. Number on registry-book, 95,716; out-patients from the 31st March to the 30th of June, 308. The account of receipts and expenditure between the 25th of March and the 24th of June, gave the following unfavourable results:—The expenditure included a balance from last account against the society of £173 18s. 4d.; the total being (including purchase of stock, £1040 10s. 6d.), £3337 4s. 1d. The total amount of receipts was £2301 3s. 6d., leaving a balance against the society of £1036 0s. 7d. The report was adopted; and some formal business having been transacted, the court separated with a vote of thanks to the chairman.

## DISPENSARIES AS SCHOOLS OF MEDICINE.

In a recent number we directed attention to the importance of our Dispensaries as schools of medicine, or rather to the capabilities which they possess in this respect, which a little fostering and proper adaptation of means to that end would unquestionably develop into an importance in many respects greater than that of the Edinburgh Royal Infirmary, yet not in the least interfering or clashing either with the claims or the teachings of that admirable and most useful institution. A glance backwards into the history of the Royal Public Dispensary, as related by HUGO ARNOT in his interesting "History of Edinburgh," and a comparison of the mode in which the business of the dispensary was transacted then with that which the great increase in the number of patients renders absolutely necessary now, will show at once how correct our estimate of its capabilities is, and how consonant with the aims and wishes of its founder is the idea of its being a medical school supplementary to the Royal Infirmary, as well as how utterly hopeless it is even to attempt to make any such use of it until there is a complete re-arrangement of the present mode of transacting the dispensary business, and, in particular, a large increase of the medical officers, for whom, no less than for the students, it forms an ample field of tuition and a means of increasing and ripening their experience, and thus rendering it more useful. Mr. ARNOT says (page 553):—"Patients who are deemed proper objects for this charity, receive advice at the dispensary from the physicians of that charity, who give regular attendance for that purpose at a certain hour, four days in the week. A full account of the disease of every patient, taken down in writing by the medical assistant at the dispensary, is inserted into a register kept for that purpose; and to the history of the case there are afterwards subjoined regular reports of the progress of the disease during the course of the patient's attendance at the dispensary, and of the effects resulting from the medicines which are employed."

Mr. ARNOT then goes on to say that one source of the revenue of this dispensary is a "small annual fee, exacted under the name of medicine-money, from students of medicine who attend the lectures given by the physicians of the dispensary, on such singular and important cases as occur;" adding, "the utility of this institution, as giving a foundation for medical lectures must be great, and it is universally admitted that no branch of medical education is better calculated for conveying useful information to students than proper remarks on diseases as they occur in practice." It was easy, however, to carry out this unquestionably most useful plan of medical tuition in those days when the patients amounted to only 222 in the first year after the dispensary was opened, and to 511 in the second year—that is, to not more than one or two in the day; but now, when the patients seen by the physicians during six days of the week amount, as they did last year, to upwards

of 7000, or an average of 23 every day, it is wholly impossible to make any useful record of the cases and their treatment, or even to convey any practical information in this respect to the student, except, as we have already mentioned, the mere parrot-like routine of this prescription for pleurisy, that for bronchitis, and something else for hooping-cough. Yet it is obvious that benefit to the students was one great object in founding the institution, and it is equally obvious that when this benefit is obtained by a more careful examination of the patient, a more exact discrimination of his disease, and a more accurate apportionment of the remedy, it will also redound to the benefit of the patient. The interests of humanity, therefore, no less than the requirements of medical science, call for some re-arrangement as to the carrying out of the Dispensary work. If, however, we have fallen off in one respect since the days of ARNOT, we have wonderfully improved in another; he states that for an annual revenue of £100, "upwards of five hundred patients may be admitted to the benefits" of this dispensary; and this he seems to think but a small sum to produce such great results. Four shillings a patient is, however, far too magnificent a sum for the present day, and we now obtain, let us hope, the same good results for a sum amounting to only *sixpence farthing* per head, 11,224 patients having been treated during last year at an expense of only £294 17s. 1d.; or if we exclude all those who got trusses and paid for them (at a reduced rate however), those who were merely vaccinated, and midwifery cases, then we have a total of 9352 patients treated for the same at an expense of only sevenpence. Surely sevenpence never were so profitably expended before; and remember this includes not only medicines, bandages, &c., but every disbursement incidental to the establishment. We think that if this charity requires remodelling in some things it requires it more especially in this, that it acts too much in accordance with the injunction, "let not thy right hand," &c. and does not sufficiently blow its little trumpet for we—readers of RENAN and of ECCE HOMO—are slightly in advance of that teaching—suitable enough for its own age—and we now require a little titillation of our ears to open our purse strings. Seriously speaking, however, we think that the managers of our dispensaries would do well to request reports from the past as well as the present medical officers as to the best mode of rendering these charities most useful for the two great objects intended in their institution, the instruction of the students and the good of the public.

THE *Wiener Medizinische Wochenschrift* says that in one of the suburbs of Vienna there lately appeared a strange epidemic—the main symptom being swollen, sore, and painful faces—attacking only the male sex. The disease was traced by the medical men to the use of a shaving-paste, which had been highly recommended as a "clean shave" by Barber Johann Gautier. His paste rendered unnecessary the use of the razor. The privileged paste was found to consist mainly of arsenic. Of course it was confiscated, and the aspiring barber subjected to legal penalties.

## Correspondence.

### NEW MEDICAL CLUB (THE SYDENHAM).

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reply to the applications of your numerous Irish correspondents for further information respecting the terms of membership of the above club, I beg to state that the rate of payment for members joining at the commencement will be as follows:—Practitioners resident within the postal district of London, five guineas entrance, and three guineas annual subscription; those resident beyond, three guineas entrance, and one guinea annual. The last scale will, of course, apply to Irish members, as well as to others in the United Kingdom and Her Majesty's service. In the case of members employed on foreign service, or residing abroad and unable to avail themselves of the club, the annual subscription will cease during such absence. Extra metropolitan members removing to London would be required to increase their entrance fee and subscription to five and three guineas respectively.

The club will provide for its members all the advantages and comforts of a temporary home, at a cost considerably lower than what they would be required to pay at an ordinary hotel, but without the annoyances and inconveniences attending the same.

Early in October next the committee propose to hold a general meeting for the purpose of submitting to the profession the rules and regulations to be adopted by the members of the club. Notice of such meeting will appear in all the medical journals.

Several gentlemen have kindly offered to assist as local secretaries for counties, which offer the committee cordially accept, and trust that others may be induced to adopt the same course, so that the club may find a cordial reception in every town and county in the United Kingdom. By this means an institution will be built up, the social and political importance of which cannot fail to be felt and appreciated.

—I am, yours, &c.

LORY MARSH, Hon. Sec.

July 20, 1866.

### THE STATE OF THE DRUG TRADE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your last number I observe a letter from Mr. James Martin, in which he impugns my statement that there are patients upon whom the one-sixteenth of a grain of aloes or the one-eighth of a grain of rhubarb act as efficient purgatives, stating that such an assertion is a mere coquetting with homœopathy, and explaining it after his own fashion by a hypothetical case, in which a patient one day fancies himself purged by these small doses, and the next fails to be relieved by a larger dose of the same medicine. Now, I beg to tell Mr. Martin, that to give a material dose, however small, which is capable of producing a physiological action, is not homœopathy, and is completely opposed to the principles of that delusive system; further, that the patients to whom I referred in penning the statements referred to, are in the habit of taking these doses—as aperients—when in their ordinary good—if not robust—health; that their bowels fail to be acted upon by smaller doses, while larger doses of the same drugs always produce hypercatharsis. If this be not proof of the activity of these small doses, I am at a loss to know what proof would be sufficient. Moreover, if the one-fourth of a grain of quinine be acknowledged by Mr. Martin to be an effective dose of a drug of which twenty grains is often prescribed with only beneficial results, I am at a loss to know why, under certain circumstances, one-sixteenth of a grain of Barbadoes aloes should not act effectively, when under all circumstances one or at the most two grains will be found

amply sufficient. The discrepancy between the doses is not so great by more than one-half in the one case than in the other; one-fourth of a grain being one-eightieth of twenty grains, while one-sixteenth of a grain is but one-thirty-second of two grains, or one-eightieth of five grains—a larger dose of Barbadoes aloes than I should ever like to prescribe. I submit that the analogy between the doses is very great; between the actions of the drugs I acknowledge there is none.

Quite recently I had under my care a lady in whom the quarter of a pill, containing as its active ingredient one-eighth of a grain of podophyllin—that is, one-thirty-second of a grain of that drug—proved perfectly efficacious, while a larger dose acted too violently. Fully cognizant of the various fallacies in regard to the fancied actions of drugs, I have watched these cases and experimented upon them in such a way as fully to satisfy my own mind as to the truth of my statement in regard to the active agency of these small doses; and if Mr. Martin has not been fortunate enough to observe any similar cases, that of itself does not disprove their truth, neither does it justify him in explaining away my positive statements by hypothetical assumptions, the obvious fallacies in which could scarcely elude the observation of the veriest tyro in medicine.—I am, yours, &c.

THE WRITER OF THE ARTICLE REFERRED TO.

Edinburgh, July 20, 1866.

### POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your giving insertion to the reply to the letter I addressed to the President of the Poor-law Board, on July 9th:—

“Poor-law Board, Whitehall, July 10.

“SIR,—I am directed by Mr. Garthorne Hardy to acknowledge the receipt of your letter of the 9th inst., and to thank you for the papers forwarded with it. He regrets that, as he has scarcely entered upon the duties of his office, he is unable at present to make any appointment for an interview.—Your obedient servant,  
J. STEWART HARDY.”

In the House of Commons, on July 7th, Mr. Hardy said:—

“I quite admit the present evil condition of the infirmaries throughout London. It is in the power of the Poor-law Board to take care that there is efficient and sufficient medical superintendence, and that the salaries of the medical officers should be fixed at a proper sum. It is also in the power of the Poor-law Board to take care that there is sufficient nursing. I trust that the House will allow me a little time, now that I am wading through a vast mass of information, for I can assure hon. gentlemen that I am desirous to apply a remedy. I think the powers of the Poor-law Board have not been put in force, and I ought not to ask the House to legislate until I have tried them (hear). In the next session of Parliament I shall be prepared to state what course I may think proper to recommend in respect of any new legislation.”

From the foregoing statement of the President of the Poor-law Board, I think there can be little doubt he fully intends to place the poor-law medical relief of this country in a more satisfactory state than it is at present, and trusts the time is not far distant when the Poor-law Medical Officers will be fairly remunerated for their services. Allow me here to call attention to the report of Dr. Edward Smith, medical officer to the Poor-law Board, which has only just been laid before Parliament. He says (page 62):—

“It should not be impossible to arrive at an agreement amongst medical men as to the sum which should be regarded as fairly sufficient. If the recommendation already made be effected—viz.:—That the guardians in all cases provide drugs and in suitable cases a dispenser, would it not be satisfactory generally for the salary to be calculated at the rate of 10s. per adult, on the average maximum number of inmates, in the workhouse at one time, two children as defined by the Poor-law—viz., persons under sixteen to be

considered as an adult." He also says: "That extras for midwifery, &c., as allowed by the Poor-law Board, should be added; and the medical officers should sign lunacy certificates, and receive the fees. This would require a considerable increase in the salaries of nearly all the medical officers, and particularly of those in the larger workhouses, and it would probably lead the guardians to appoint one or more resident medical officers to each workhouse, who would devote their whole time to the duties of the office."

Should Mr. Garthorne Hardy, after a reasonable period, fail to name a time for me to present the petition of the meeting of July 5th, I will again communicate with him, but I think it hardly fair to press him now too much, considering the statement made by him in the House of Commons, "that he is wading through a vast mass of information," but rather give him a little breathing time—I am, &c.

RICHARD GRIFFIN.

12, Royal Terrace, Weymouth,  
July 21, 1866.

**THE ENGLISH POOR-LAW MEDICAL SERVICE.**

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The time is now come that all Poor-law Medical Officers should put their shoulders to the wheel, by making their own cases well known to the general public, by and through the medical journals and other periodicals of the day. They should state the amount of labour they get through—the number of cases yearly—the acreage they traverse—the population of their district, and the cost of the medicines they supply—if allowed an extra amount of salary for expensive medicines, or if supplied by the guardians—the expense of an assistant to dispense for the paupers, and that of a horse, groom, and carriage, where the duties cannot be performed efficiently without, from the numerous cases, or where the acreage is extensive. These cases might be put in juxtaposition with the dispensary surgeon, who is certainly much better paid than the Poor-law Medical Officer. In a general way he gets a house to live in, rent, coals, gas, an assistant, and the medicines free, with a salary from £100 to £120 per annum. In my case, as a parochial medical officer, I have the largest district of a large town, wherein is a public hospital and dispensary, the population of which is about 12,000, more or less, and the acreage near upon 3000. The number of orders issued last year for my attendance by the relieving officer were a few short of 1500. The first half of the present year, ending Lady Day, they were over 900. A large majority of these cases were visited at their own homes, and in all cases medicines were supplied at my cost (the guardians allowing nothing extra for expensive drugs). Through the winter and spring the number visited generally average from 80 to 90 per diem; while through the summer and autumn they are somewhat less. I find I cannot get through my work—to do my duty efficiently—without an assistant to dispense for them, and a horse, groom, and carriage to visit them, the salary for which is under £100 per annum. Now, the expenses per annum may be stated as follows:—

|                                                                                                                                      | Per annum. |
|--------------------------------------------------------------------------------------------------------------------------------------|------------|
| Pay and keep of an Assistant . . . . .                                                                                               | £50 0 0    |
| Drugs and Chemicals . . . . .                                                                                                        | 40 0 0     |
| Keep of Horse, pay of Groom, sundries for<br>Repairs, Stable Utensils, and assessed<br>Taxes on Horse, Carriage, and Groom . . . . . | 100 0 0    |
|                                                                                                                                      | £190 0 0   |
| Necessary Expenses . . . . .                                                                                                         | £190 0 0   |
| Salary and Vaccination Fees . . . . .                                                                                                | 120 0 0    |
|                                                                                                                                      | £70 0 0    |

No other extras, except an occasional midwifery case.

The work is, therefore, done for the guardians at a loss of £70, or thereabouts, to the Medical Officer. Now for the extras—ah! what are they? Many may expect from the population of the district that a good amount might be expected from them. I foolishly thought so too when I read

the remuneration of the Medical Officers issued by the Poor-law Commissioners, but I was grievously disappointed after I was fully installed and confirmed in my office. I soon became acquainted with all the hard work, the visiting and dispensing. Also that all pure surgical cases—wherein are enumerated fees—were sent to the hospital, and all midwifery cases given to a midwife; and when she is not found equal to her duties, she is allowed to send for me, and an order is obtained; and if this cannot be proved to be a "special" case, the sum of ten shillings only is paid. The only extras really that pay are for vaccination, and these bring the salary up to £120 per annum. In the town where I am resident the dispensary surgeon gets his £120 per annum; lives in a good house; rent, rates, taxes, coals, gas, an assistant and drugs free. How different to the Poor-law Medical Officer! Note the contrast.

Now for the remedy. This might be either by doubling the present amount of salaries, or in all large towns the guardians to find drugs, an assistant, and dispensary for the united parishes, and the medical man of each district to be paid the same amount as now, to visit and see all in his district, giving the paupers his prescriptions, or taking them himself to the dispensary, or a dispensary and assistant to be in each district of the union.

I shall feel much obliged if you can publish this letter in your next publication. I enclose my card—but at present withhold my name and address—and beg to subscribe myself a hard-worked and ill-paid

POOR-LAW MEDICAL OFFICER.

July 21, 1866.

**CATTLE PLAGUE DISINFECTANTS.**

THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the "Summary of Science," by Mr. Tichborne, contained in your number of last week, there are some statements in reference to Mr. Crookes' report on disinfectants, in connexion with the cattle plague, which appear to me to require rectifying. It is therein asserted that "Mr. Crookes' experiments have all pointed to the value of crude carbolic acid as a disinfectant." This assertion is clearly calculated to give the impression that Mr. Crookes instituted a series of practical experiments with a considerable variety of disinfecting agents, and that, on the result of such experiments, was based his recommendation of some of them, and his rejection of the others. But what are the facts? That so far from this being the case, Mr. Crookes stated on the inquiry, which had been entrusted to him, on the principle of investigating those substances only which were approved of by Dr. Angus Smith. "By his exhaustive examination of disinfectants," he sets out by explaining, "Dr. Angus Smith has rendered it unnecessary for me to search amongst the numerous class of possibly useful bodies, for those likely to be of practical value. His results I accept in the full conviction that they are correct; and I proceed to investigate the respective merits of the comparatively small number of agents available for disinfection . . . . The choice is limited to chlorine and ozone, and the antiseptics, sulphurous and the tar acids." Mr. Crookes thereupon tries one laboratory experiment with chlorine, to prove that that body acts more rapidly on oxidisable gases than on living cheese-mites, and on that result, supported by certain speculative considerations, rejects that powerful disinfectant as disqualified for combating the infection of the cattle plague. Without instituting any experiment at all, he then rejects ozone, for theoretical reasons alone. There consequently remained only sulphurous and the tar acids to experiment on, and a reference to Mr. Crookes' report will show that from paragraph 29, in which he dismisses ozone, to paragraph 9, which contains the last reference to experiments, he treats almost exclusively of carbolic acid. Such

being the case, it is not a little remarkable, that Mr. Crookes, further on in his report, should have ventured to express himself as follows:—"I am bound to admit, that the conclusion, to which I have been forced to come, is quite opposed to my pre-conceived ideas on the subject. I started with a strong bias in favour of chlorine and ozone, but the irresistible force of the arguments, derived from my experiments, has caused me to alter my opinion."

The next statement in the Summary which requires comment is the following:—"Mr. Crookes' experiments prove exclusively that carbolic acid does not retard or hasten oxidation; most other disinfectants do. It is therefore properly an antiseptic." In regard to this point, it must be allowed, that Mr. Crookes did make conclusive experiments, and did prove that carbolic acid has little or no action on purely chemical ferments, nor on the chemical products of infection, and that it is not an oxidising disinfectant at all, but merely an antiseptic. But the intervention of Mr. Crookes was not required to prove this. It was undisputed, and to be found clearly stated in every modern English work on disinfectants.

The last statement in the Summary which demands notice is this:—"In every case where the carbolic acid was injected marked improvement was evident, and in some cases the animals recovered . . . . One cow that recovered bore the injection, &c." Now, he would be a clever person who could gather from the above that out of five cases of plague-stricken cows treated with injections of carbolic acid, all died except one. Yet this, which differs but little from the general rate of mortality in rinderpest, was the actual result, as the subjoined table will show:—

| Distinguishing number of Cows operated on. | RESULT.                    |
|--------------------------------------------|----------------------------|
| 10 . . . . .                               | died on 6th day.           |
| 11 . . . . .                               | died on 6th day.           |
| 12 . . . . .                               | died on 6th day.           |
| 13 . . . . .                               | killed by first injection. |
| 14 . . . . .                               | slowly recovered.          |

And these are the experiments which, according to Mr. Tichborne, "have a broad bearing upon contagious diseases in general." Is there not reason to suspect that the favourable opinion which that gentleman entertains of Mr. Crookes' labours has originated in the circumstances stated by him, that "the use of carbolic acid as a disinfectant was advocated by him many years ago."—Yours obediently,  
M. D.

#### THE TREATMENT OF THE SICK POOR IN THE STRAND WORKHOUSE, LONDON.

At the weekly meeting of the Guardians of the Strand Union, the Clerk read the following communication from Dr. Rogers:—

"Dean-street, Soho, W., June 17, 1866.  
"GENTLEMEN,—Having been informed that a member of your Board has given notice of a motion for this evening of a want of confidence in me as your medical officer, I consider that it is a duty I owe to myself to forward you an outline of what I have done, or have attempted to do, since I first held office. When first appointed, ten and a half years ago, I at once introduced at my own cost the materials, &c., for a dispensary, &c., nothing of the kind having before that been provided in the building. Shortly after assuming office I learnt that the beer and wine, &c., ordered for the sick by me were served at the early hour of seven a.m., and as constantly the day's supply was consumed before my arrival at nine a.m. I tried to get them supplied at a more reasonable hour, but I had much difficulty in so doing, owing to the opposition of the then master, and the indifference on the part of the then Board, whom I addressed on the subject. In the first summer following my appointment an outbreak of fever took place, owing to excessive overcrowding in the house. I addressed a communication to the Board, and prevailed on them to build at each wing, above the receiving wards, additional wards, and also to dig out an area in front of the ward then used for the reception of persons admitted on nightly orders. This place, called

'bugs'-hole' by the inmates, was a cellar (without area) of the most objectionable kind, and the hotbed from whence fever was largely propagated. Subsequently I induced the Board to enlarge and extend the dormitory accommodation for males and females, hereby adding considerably to the sleeping space for the able-bodied inmates. Having repeatedly noticed that the suckling women became consumptive, or suffered from diseases of an exhaustive character, and that many of their children died, I found on inquiry that the dietary of the lying-in ward, over which I had then no control, and was not supposed to enter without the request of the master or midwife, was very insufficient, as it consisted of gruel only for nine days, and that when discharged to the nursery they went at once on the common diet of the able-bodied inmates; and, believing at that time the Poor-law Board alone possessed the power of altering this, I wrote to that Board on the subject, urging an alteration. In their reply they informed me that I was to be the sole judge of the dietary of this class of inmates; and, having acted in accordance therewith, the then Board of Guardians, some of whom are still members of your body, passed upon me a vote of censure for this act of duty and humanity. Some two years after I suggested the building of a laundry out in the yard, thus removing a pregnant source of ill-health to the inmates; this work having been previously carried on under the entrance-hall, &c., causing the house thereby to be filled with steam and damp. This having been achieved, the accommodation in the house was largely added to, as thereby the men and women's dining-halls were converted into infirm wards, and the old laundry into a dining-hall. On or about this time I suggested the conversion of the dormitories at the top of each wing into sick wards by removing the ceilings and plastering the rafters, and the removing my acute cases there; by this alteration about 250 cubic feet of air was added to each sick inmate, and the chance of the occurrence of erysipelas, fever, &c., was greatly diminished and a better prospect held out for the speedy recovery of all. Shortly after this, and owing to a large increase in the number of aged and infirm persons, I suggested to your Board an important alteration of the dietary of this class of inmates; thereby much suffering from improper food and waste was put a stop to, and a diet more suitable was introduced. This form of dietary has since then been largely adopted by the various metropolitan union houses. I was repeatedly informed by individual members of your Board, and it is correct, that these successive applications evoked much offensive personality and antagonism, and I have been strongly advised by them to keep quiet and not trouble the Board with repeated applications for improvement. In the year 1862 a severe outbreak of fever took place in the building, due solely to overcrowding; twenty-five cases occurred in quick succession. I wrote urgently to your Board on the subject; an extensive exodus of inmates was ordered, the crowding ceased, and the fever also. On or about this time I suggested to the visiting committee an alteration of the dead-house, the grating, &c., from which opened beneath the windows of the women's infirm wards. This place was a part of the carpenter's shop, and separated from it by an imperfect partition. From the grating foul emanations from the dead frequently arose and filled the wards, and in the summer large blue flies flew in and out of them from the dead-house. I made this application to the committee, over which Mr. Joseph Smith presided, but they refused to entertain the question. Shortly after the coroner for Middlesex commented severely on the impropriety of using such a place for such a purpose, and the subject was brought before a second committee, and a proper dead-house was constructed. In 1863 I drew the attention of the Board to the advisability, on the score of economy, want of space, and general absence of accommodation, of subscribing to the Middlesex Hospital, so as to relieve the house of cancer cases, many with this disease having been admitted. The suggestion was adopted, but I heard that Mr. Betts, and some other members of the Board, indulged in offensive personalities. Again, in the same year I advised, with success, the removal of syphilitic cases to the Lock Hospital as soon as possible after they were admitted. Motives were attributed to me by the same members of the Board for my advocacy of this necessary change of the most unfair and unworthy character. In 1864, overcrowding of the house having again taken place, I addressed a written remonstrance to the Board, and pointed out that a malignant fever had broken

out in the house. They thereupon adjourned to it. A large measure of out-door relief was directed, the crowding ceased and the fever also. In May, 1865, the Poor-law Board addressed you on the subject of pauper nurses, and strongly advised you to engage paid and respectable persons, thus taking up a question upon which I had long felt deeply the necessity for change, and which I had tried to induce several members of your board at various times to bring before you. This matter I should have written to your Board about myself had it not been for the determined opposition of certain officials to the introduction of paid nurses. Your Board, however, engaged one, and by the terms of the advertisement limited her attendance to those patients only who were in the two sick wards, amounting to about forty persons; and yet the house contained, as you are aware by the weekly returns, over four hundred sick, aged, and permanently disabled persons, who were thus left to the care of those who had been officially condemned by the Poor-law Board as untrustworthy, and over whom, though I was theoretically supposed to have control, yet practically I had none, for their selection and dismissal were left wholly in the hands of the master and matron; such was the rule when I assumed office, and up to the present time has not been altered. Over and over again I have requested a particular nurse to be removed for inefficiency or worse, but have been nearly always met by the reply that there was no one better suited for the post in the house. When Belsham, the pauper nurse, was removed at my instance for robbing the sick, the master, in consequence of a suggestion by me, undertook to bring the question forward and apply for paid assistance, as the circumstances were such as admitted of no delay; the total refusal, as he informed me, of the visiting committee, and the recommendation of one of the guardians to employ a broken-down potboy, whose antecedents he so well knew, was a proof, coupled with what I have above referred to, that it would be a mere waste of time to make any further communication with your Board on the subject. At the early part of the year 1864, the late Mr. C. Jeffreys moved that my salary should be increased; I waited upon him and others whom I knew to be favourable to me, and urged them to get your Board to provide medicines instead, as I wished to establish the principle that in such a large house as the Strand all the drugs should be found at the cost of the rate-payers, thereby evincing that I had some other feeling in the matter save that of getting a little more money. Your Board assented to the proposition, but limited my outlay on this head to £30 only on the year. With respect to the carpet-beating, I apprehend that the members of your Board who were also members of the last, can by no means endorse the assertion of Mr. Cane, that they were not aware of my opinions on the impropriety of that practice. Your chairman personally dissuaded me from communicating those opinions to your Board in writing, but also Mr. Storr's committee on the subject refused his request to hear me, alleging that they were aware that I held an opinion adverse to its continuance. Your Board is also perfectly cognizant that I strove to relieve the house by soliciting the Middlesex Hospital authorities to take some of our sick; that I suggested the scheme of writing to the various unions round London, soliciting them to take some of our inmates; that when six of my patients were removed to Guy's Hospital, not only was a resolution put on the paper to reduce my salary, but that it was adjourned from week to week, while also the Board sanctioned a return of my salary, fees, &c., and the cost of medicine and appliances,—a course of conduct not dictated by a very generous feeling towards me. Seeing that your Board has been lately reconstituted, I have felt it just to myself to lay before you this brief outline of the continuous efforts that I have made, not only to perform faithfully my daily routine duties, but to obtain successive improvements and ameliorations in the interests of the sick inmates of your house. I have regretted many times, and deeply, that these efforts, instead of receiving the cordial sympathies and assistance of past Boards, have entailed upon me much annoyance, hostility, and undeserved insult. I am happy to believe your Board, as reconstituted, will view with more favour my efforts in this direction, and "Gentlemen, I am, yours very respectfully,

"JOSEPH ROGERS."

After the reading of this letter, it was moved and seconded that Dr. Rogers be requested to resign his post as medical officer to the Workhouse; but an amendment was proposed, and on a show of hands, the numbers were found to be equal.

## Notes on Current Topics.

**LONDON HOSPITAL.**—In consequence of the number of cases of cholera that have recently been brought to this hospital, the Committee have postponed the celebration of the anniversary and the ceremony of opening the Alexandra wing. Apart from the probability that any attempt to hold a festival in the centre of the district that has been smitten with the epidemic, and a natural indisposition to invite the Heir Apparent to take such a risk, we cordially agree with the Committee that, under existing circumstances, it is rather their duty to devote all their energies to the preparation of the new wing for immediate occupation. We hope, therefore, that the funds of the hospital will not suffer, but that the friends of the charity will increase rather than diminish the contributions they had intended to offer. In connexion with the calamity that has caused the postponement, it is a pleasure to be able to record that a young lady has been toiling for many days as an amateur nurse in the cholera wards of this hospital, and that her valuable assistance is thoroughly appreciated, both by the professional staff and the paid nurses, as well as by the unfortunate patients.

**THE VACCINATION ACT.**—We regret that amongst the "massacre of the innocents," the amendment to the Vaccination Act is likely to be sacrificed. Although the poor are almost invariably the greater sufferers in every epidemic of small-pox, mere selfishness might well urge our legislators to insist on some more stringent measure to ensure an observance of the regulations, since every infected house only serves as a fresh focus of contagion. Some anxiety has been felt on account of the recent outbreak of small-pox in London. It has been ascertained that in Spitalfields, where the epidemic has chiefly raged, there has been an utter neglect of vaccination. This in a crowded, poverty-stricken district, has only produced its natural crop. A house-to-house visitation could never be more appropriate than in the case of a visitation of variola, since a careful inspection would in each case determine the degree of protection that has been obtained. We commend the idea to all interested in sanitary matters.

**PUBLIC HEALTH BILL.**—It is satisfactory to learn that the Privy Council has adopted this important measure, and that therefore there is some hope of its passing the legislature. Among its most important provisions we may signalise its requirements to provide sufficient public drainage and a wholesome supply of water; to ascertain what nuisances exist and enforce their removal; to furnish carriages for the conveyance of infected persons to hospitals, and proper receptacles for dead bodies; and to regulate the lodgings that may be separately let, and the number of inhabitants that may occupy any tenement. Some other new and important powers are conferred, and as the Bill comes before the House with the authority of a select committee, it is possible that it may pass in its integrity. Surely in the present state of the public health, Parliament can devote the time necessary for passing into law such valuable provisions.

**HOSPITAL VENTILATION.**—The recommendations of

Dr. Edward Smith to the Poor-law authorities have caused a good deal of conversation in medical circles, and been subjected to an unusual amount of criticism. Dr. Smith had deduced from some of his own experiments that 500 feet of cubic space, with 55 to 60 feet of superficial floor-space per patient would be sufficient. To this no less an authority than Dr. Parkes has deemed it his duty to reply, arguing for the necessity of at least 1000 to 1200 cubic feet with 80 feet of superficial floor-space to each person. With the greatest possible respect for the usual accuracy of Dr. Edward Smith's experimental researches, we feel ourselves obliged, in this instance, to endorse the opinion of Dr. Parkes, in which we believe scientific and practical men will eventually concur. We trust, therefore, that Dr. Smith will yet retract his advice to the Poor-law Board.

**LONDON SURGICAL HOME.**—From the proceedings at the eighth annual meeting of this institution we gather that the Prince and Princess of Wales, have become patrons during the past year, and that £1908 17s. 5d. has been received in donations, and that the patients have contributed £1022 5s. towards the expenses. The Committee have just taken the adjoining premises, which, when fitted up at a cost of about £500, will afford accommodation for twenty additional beds.

**RESULTS OF THE HYDE PARK AFFAIR.**—From its position St. George's Hospital received the largest number of the wounded, 48 cases in all. St. Mary's afforded relief to 12 others. A large number had only slight wounds about the head and face from staves, stones, &c. Among the more serious cases were—1. A dislocation of humerus into axilla. This patient was otherwise severely bruised, and suffered from an effusion into the knee-joint. 2. Case of concussion of the brain complicated with injury to thorax, causing absence of respiratory murmur all over the right half of the chest. 3. Concussion caused by blows from a truncheon; sense soon recovered, but vertigo remains. 4. Fracture of fibula and other injury to the leg. 5. The boy crushed to death between two carriages; but this case scarcely belongs to the Hyde Park disturbance, the accident having occurred in Grosvenor-place, and being quite unconnected with the conflict. 6. Injury to liver by blow from an iron bar. Altogether upwards of sixty persons sought hospital relief. Probably an equal number went home having slighter wounds. Considering the immense crowd of people, and the excited state of both parties, this is not a very serious list of wounded. From it we may fairly conclude that each party has somewhat exaggerated the "brutal ferocity" of its opponent. In what country could a conflict take place between such numbers and the police without much more formidable casualties?

**THE JEWS' HOSPITAL**—The anniversary festival of this institution took place on the 21st, the Right Hon. the Lord Mayor in the chair. The Hospital is situated at Norwood, and is intended for the support of the aged and the education of the young; 12 old men and women, 33 girls in the school, and 89 boys, are now in the house. The income of the charity is about £1800 a year. About £1500 was announced as the amount of the list of subscriptions and donations for the evening.

**HOSPITAL CHANGES IN LONDON.**—Dr. Gull is suc-

ceeded at Guy's by Dr. Habershon, and the Assistant-physiciancy has been conferred on Dr. Moxon. At the London Hospital Drs. H. Jackson and G. H. Sutton have been appointed additional Demonstrators of Pathology, and Dr. Mackenzie joint-lecturer on Physiology. Dr. A. B. Shepherd has been elected an Assistant-physician at the City of London Hospital for Diseases of the Chest in Victoria Park. Dr. Jenner accepts the post of Consulting-physician to the Hospital for Diseases of the Throat.

### MEDICAL REPRESENTATION IN PARLIAMENT.

DR. MACKESY of Waterford presided at the annual meeting of the Irish Medical Association, held at the Royal College of Surgeons on the 5th of June. Alluding to other subjects more or less briefly, the principal topic he discussed was the desirableness of a representation of the medical profession in Parliament.

Dr. Mackesy's views may be shortly stated thus:—The medical profession is not represented in Parliament. There are medical men in Parliament, indeed; but they have not been sent there by the medical body, but by the public—not as representatives of the profession, but as politicians. It is not remarkable, therefore, if they have "not distinguished themselves in connexion with subjects affecting the public health." He suggests the representation of the profession directly. We do not understand quite clearly whether he would devolve the election of members upon the colleges exclusively, or upon the members of the profession and the colleges together. To the colleges or the members, however, he would give the right of electing members of Parliament. He thinks the presence of such men in the House of Commons would be a great accession to its power of dealing wisely with social and sanitary questions, and "would render unnecessary the circuitous and expensive resort to Royal Commissions of inquiry." In support of this view he argues that the Law and the Church have both a virtual representation in the House of Commons, to say nothing of their strength and standing in the House of Lords.

It is due to Dr. Mackesy, to the Association he represents, and to the importance of the subject, to give publicity to his views. There can be no doubt as to the advantage which would accrue to the public by the choicest members of our profession taking part in the discussions of Parliament. But this is the public's look-out. If they are alive to the conspicuous absence of a Minister of Health or any public official that can speak with personal weight and authority on the most vital of all questions—the health of the people—it seems to us that any proposal to supply this defect should originate with the public, or with its representative—Parliament. With the growing attention that is being given to the health of the people, it can scarcely be much longer unnoticed that, while we have Ministers that speak authoritatively on foreign affairs, on points of law, and on questions of education, we have not one who is able to deliver authoritative opinions upon questions touching the health of the community. This ability is so obviously one of the first functions of Government that it cannot always or much longer be entirely ignored in the construction of a Ministry. Its absence is the more to be regretted as there is no end of good work to be done by wise legislation on sanitary subjects. Thousands of lives—adult and valuable lives, as well as lives of children—are to be saved annually, and the comfort and civilization of the people generally are to be correspondingly advanced by anything like competent work in this direction. But we have no faith in the complete discovery of the absurd defect in our executive unless it is made by the public themselves. We must not make choice medical opinion too cheap. If Sir Thomas Watson or Dr. Burrows, or any man of equal standing, is to be tempted into Parliament, or to have due weight when

there, it can only be by making a place in the Government which would be fitly filled by such men. Until some such recognition of the value of State Medicine takes place, we should scarcely care to see the leading members of our profession take much thought about getting into Parliament. Such thought would distract them from the high pursuits of their own profession, without securing to them a corresponding influence in Parliament.

In the meantime, it seems to us better that the medical profession should occupy itself in the cultivation of accurate and scientific opinion on sanitary and medical subjects rather than in the attempt to secure for itself or for its corporations a special representation in Parliament. Dr. Mackesy's proposal is, we fear, objectionable. In the first place, it is inconsistent with our system of representation. There is nothing strictly analogous to the representation of the medical profession which he proposes. No other class, professional or commercial, has the power of electing members of the House of Commons. Were such a power granted to the medical profession it is easy to see that other "classes" would claim a special representation, and that in course of time our House of Commons, instead of representing a heterogeneous constituency, would represent special interests and classes. This would be entirely to alter the principle of our representation. The alteration, it seems to us, is neither practicable nor desirable. It is certainly not practicable. Anyone who has watched the failure of an attempt just made by a Government, and by a statesman of surpassing ability, to merely extend the representation of the people upon an old principle, will be satisfied of the certainty of the failure of any attempt to introduce so novel a principle as that involved in Dr. Mackesy's address. And, if it were practicable, it would not be desirable. We have no interests apart from those of the community. If the community likes to keep up the preventable disease which abounds in it that is scarcely a reason why we should ask for a special representation in Parliament. It will always remain a mystery of benevolence that the greatest promoters of the health of the people are the men who live by the diseases of the people. But there is a limit to our duty of urging the community to consider its health. We may discharge our duty, we may satisfy our conscience and even our benevolence, without making vain demands, which might be misconstrued, for admission, as medical men, into Parliament.

The representation of the Church and the Law, instanced by Dr. Mackesy, is not strictly analogous to the representation of Medicine which he proposes. The University members in the House of Commons can only in a very qualified sense be considered representatives of the Church. And as the universities widen in their character, as they certainly will do, this representation of the Church will be more qualified still. The law officers of the Crown in the House of Commons are chosen, not as lawyers by lawyers, but as political men by the ordinary constituencies. The representation of Law in the House of Lords arises entirely out of its character as a law court.

We repeat that we should be glad to see a few of the leading members of the profession in Parliament. And when Parliament has made an office which such men could accept with advantage to the public and with honour to the profession, we believe that their election will be practicable in the ordinary way.—*Lancet*.

## Parliamentary Intelligence.

### HOUSE OF LORDS.

JULY 19TH.

#### DISINFECTATION OF SEWAGE.

A BRIEF discussion arose upon the motion of Lord SHREWSBURY for a Select Committee to inquire into Mr. Dover's method of disinfecting sewage; but although the merits of the plan were well spoken of, Lord Derby thought the subject was one which should be dealt with by the Royal Commission upon the Pollution of Rivers, and the motion was not pressed.

JULY 24TH.

#### VACCINATION.

The Earl of SHAPTESBURY asked what steps would be taken during the present session in respect of the Bill regulating vaccination. He stated that in 1863 there were 3000 deaths from small-pox in London alone; in 1864 there were in the country 7684 deaths, indicating 20,000 cases, and there were now symptoms of a growing prevalence of this disease. He trusted that the Government would proceed during the present session with a Bill on this subject now before the other House.

The Duke of BUCKINGHAM, in reply, said that it was found desirable to postpone the consideration of the Bill until next Session.

### HOUSE OF COMMONS.

JULY 20TH.

#### ARMY MEDICAL OFFICERS.

General PEEL, in reply to Colonel North, said there would be no objection to lay upon the table of the House the report of the committee on the position and pay of the medical officers of the army and navy, which had already been moved for that evening. He was happy to say that it was intended not only to adopt the recommendations of the committee in favour of medical officers of the army, but to go beyond them (hear). Nothing was taken in the present estimates for this service, and it could not, therefore, come into operation until the beginning of the next financial year.

#### CATTLE DISEASES ACT.

Mr. WALPOLE, in reply to Mr. Read, said that no modification of this Act was contemplated at that moment. He intended to bring in a Bill to amend the Cattle Plague Act on Thursday, of which he would give notice that night.

#### THE CASE OF MR. TOOMER.

Mr. WALPOLE, with regard to some representations by Mr. Eykyn on the subject of the late extraordinary conviction and sentence on Mr. Toomer at Abingdon for an alleged rape, said that the case had not yet come officially under his notice, but he was led to believe that an application on the subject would be made to him in a day or two, and the moment it was he would give it his best attention.

#### VETERINARY SURGEONS BILL.

Mr. NEWDEGATE said it was not his intention to press the measure during the present session, but he was anxious to remove some misapprehensions which had arisen with respect to it since the second reading. The right hon. gentleman then entered into an explanation of the measure, and expressed a hope that the right hon. gentleman who represented the Education Department would give an assurance that during the recess nothing should be done to prejudice the case as it now stood.

Mr. CORRY gave the assurance asked for.

The order was ultimately discharged.

The following petitions were presented:—Against the Vaccination Bill, by Mr. Hadfield, from Eccleshall, Yorkshire; in favour of the Artisans Dwelling Bill, by Mr. M'C. Torrens, from Plumico, Westminster, and Chelsea, and also from the parish of St. Luke's; from the committee of the Dorset County Hospital, in favour of continuing the exemption from local taxation of charitable institutions.

JULY 23RD.

The following petitions were presented by Alderman Salomons, from the Greenwich District Board of Works against the Bill to provide better Dwellings for Artisans and Labourers; also from the same petitioners against the Cattle Diseases Prevention Bill, 1866; and Lord Grosvenor from the justices of Flintshire praying for a national assessment for compensation for the losses occasioned by the cattle plague.

#### THE HOUSELESS POOR ACT.

This Bill was discussed by Messrs. Bromley, Neate, and Henley.

Colonel Hogg said it would be very difficult to detain casuals in the London workhouses. In St. George's, Hanover-square, there was workhouse accommodation for the poor for between 600 and 700 paupers, which was nearly all occupied. In January, 1864, there were 346 casuals; in February last they amounted to 1282, and 775 of these had

to be accommodated in hired lodgings; in March there were 1193, and 895 had to be accommodated out of the workhouse.

Mr. HARDY, in reply, stated that there was accommodation provided in the metropolis for 2000, which was far beyond the requirements, as the number of casuals averaged 1000 to 1100.

JULY 24TH.

PUBLIC HEALTH BILL.

The House went into committee on this Bill.

Clauses up to 4 were agreed to.

On Clause 5, regulating the formation of special drainage districts,

Mr. HENLEY moved an amendment providing that the district rate be made in the same manner and assessed on different descriptions of property in the same way as a general district rate in the Local Government Act, 1858.

Mr. BRUCE declared that he could not assent to the amendment, which was lost by a majority of 74.

The clause was then agreed to, as were clauses up to 9, when the House resumed.

SUCCESSFUL TREATMENT OF CHOLERA.

MR. FREDERICK SMITH of York House, Penzance, writes to us detailing a method of treatment, pursued at Naples, by which in 592 cases not a single death occurred:—

Happily, the remedy in question is one which has been employed by all the medical schools, and can give rise to no angry debate. The dominant school, sometimes called allopathic, have used it; and that comparatively small section of the profession called homœopathic is also in the habit of prescribing it. But neither party, as a school, has thought of preparing it in the way in which Dr. Rubini—the author to whose labours in this cause I am about to refer—has found so invariably successful. For example, the ordinary spirits of camphor of the British Pharmacopœia consists of one part by weight of camphor to nine parts of spirits of wine; the homœopathic preparation of one of camphor to five of spirits of wine; whereas Dr. Rubini's preparation consists of equal parts by weight of camphor and spirits, and to the power thus obtained he attributes his success in the treatment of the disease. And here I may say that the quantity of camphor which water will take up is small. To obtain, therefore, the "saturated spirits of camphor of Rubini," it is necessary to distil spirits of wine, and get rid of so much of its water as will bring it to 60° over-proof, in which condition it will dissolve and hold in solution its own weight of camphor.

With this "saturated spirits of camphor" Dr. Rubini, an eminent Neapolitan physician, has treated in Naples 592 cases of Asiatic cholera without the loss of a single patient. Of these 592 cases 200 were cured in the Royal Alms House, 11 in the Royal Poorhouse, and 166 in the Third Swiss Regiment of Wolff. That the 377 cases treated by Dr. Rubini in these public institutions were all genuine cases of Asiatic cholera, and some "terribly severe," and that all recovered, the evidence of the following distinguished individuals, with their official seals attached, sufficiently attest—Il Generale Governatore Ricci, Il Maggiore Commandante Nicola Forni, Il Capitano Commandante Carlo Sodero, Generale Commandante Fileppo Rucci, Colonel Eduardo Wolff. "The method of cure" is as follows:—"When a man is seized with cholera, he should at once," says Rubini, "lie down, be well wrapped up in blankets, and take every five minutes four drops of the saturated tincture of camphor. In very severe cases the dose ought to be increased to from five to twenty drops every five minutes. In the case of a man of advanced age, accustomed to take wine and spirits, where the drug given in drops has no effect, give a small coffee-spoonful every five minutes, and in a very short time the coveted reaction will occur. Ordinarily, in two, three, or four hours abundant perspiration will come out, and then cure will follow." "The preventive method," writes Dr. Rubini, "is this, let those who are in good health, while living in accordance with their usual habits, take every day five drops of the saturated spirits of camphor upon a small lump of sugar (water must never be used as a medium, or the camphor will become solid, and its curative properties cease), and repeat the dose three or four times a day. Spices, aromatic herbs, coffee, tea, and spirituous liquors should be avoided."

THE CHOLERA.

THE Ven. Dr. Lee, Archdeacon of Dublin, having consulted some eminent physicians, has caused the following paper to be circulated among our poorer brethren of all persuasions in his large parish in Dublin. We highly approve of this document, and we strongly recommend our readers to urge clergymen of all persuasions throughout the country to follow Dr. Lee's example.

St. Peter's Parish, July, 1866.

The following observations are commended to your attention, as containing advice which may be found useful should it please God, in His wisdom, to permit this city to be visited by the pestilence known as the cholera:—

1. Cholera is less dangerous to those in attendance on the sick than scarlatina, small-pox, or typhus fever.
2. All rooms, yards, cellars, and privies, should be white-washed at once, before the cholera appears; and the white-washing should be repeated from time to time.
3. Cholera almost always gives the sufferer some hours' or even days' notice of its approach, by a looseness in the bowels, which is a sign that must be immediately attended to.
4. On the arrival of cholera, chloride of lime should be used freely, to purify the evacuations arising from looseness of the bowels, or from vomiting; and all such should be regularly and immediately removed from the sick room.
5. The chief danger arises from neglecting thus to purify the apartments, as well as all evacuations, by means of chloride of lime or other agents, and from carelessness in drinking water that may contain the seeds of the cholera-poison, owing to neglect of sewerage and deficient supply of pure water.
6. All water used for drinking should have been previously boiled, so as to destroy the traces of cholera-poison that might exist in it.
7. Nothing is more important than to secure a supply of fresh air in the sick room. This may be effected by lowering the upper window sash, or by boring a good-sized hole through the top frame.
8. If cramps accompany looseness of the bowels, the patient should have heated bricks placed to the soles of the feet and between the thighs, and also be rubbed well on the stomach with warm flannels while medical aid is being sought, which should be done without delay.
9. It is of the greatest moment that you should not give way to unreasoning fear, and that you should face the danger, if it comes, with Christian courage. To secure that calmness of mind, without which you cannot give any real help to your family or neighbours, you should place your entire trust in the mercy and goodness of God, on whom alone, in seasons of health and of sickness, life and death depend, remembering always, that when you are performing your duty to your neighbour, you are obeying and serving God.

A SUPPLEMENT to the *London Gazette* of Friday week contains an Order in Council, directing that the provisions contained in the "Diseases Prevention Act, 1855" (23rd and 24th of Victoria), for the prevention of diseases, shall, from and after the 14th instant, be put in force within the whole of England. Thirteen deaths have been reported from the cholera ward at the Liverpool workhouse. Nine cholera patients remain, and two at least cannot be expected to live. The select vestry have determined upon a house-to-house medical visitation of the poorer districts, and the isolation of families in which cholera has appeared, as well as the removal of actual sufferers beyond the town. They have, with this purpose, renewed their occupation of the Bank Hall warehouses, which will hold from three hundred to four hundred persons. The preparations will be completed in a few days, and then all persons stricken by cholera, all members of families in which it has appeared, and all persons whose removal is rendered necessary by the want of new sanitary arrangements in their houses, can be removed to Bank Hall. We regret to hear that the cholera is rife at Southampton. Up to a few days ago forty deaths had occurred. We believe that injudicious attempts are made to keep the fact quiet.

A PAUPER died last week at the Liverpool Workhouse at the reputed great age of 106 years.

## LOTHIANS' MEDICAL ASSOCIATION.

A MEETING of the medical profession of the Lothians was held in 5, St. Andrew-square on Wednesday week, to receive the report of a committee appointed at a preliminary meeting, and, if approved, adopt a draft constitution for the Society. The chair was occupied by Professor Christison; and there were also present—Professor Bennett, Dr. Andrew Wood, Dr. Alexander Wood, Dr. Warburton Begbie, Dr. Mathews Duncan, Dr. Dunsmore, Dr. Keiller, Dr. Graham Weir, Dr. Dickson, Dr. Bruce, Dr. Balfour, Mr. Wm. Brown, Dr. Joseph Bell, Mr. Carmichael, Dr. Sibbald, Dr. Fowler, Cortstorphine; Dr. Gordon, Juniper Green; Dr. Bryce, Dalkeith; Dr. Main, Lasswade; Dr. Peacock, Liberton; Dr. Smith, East Linton; Dr. Carruthers, Cramond; Dr. Wallace, Kirkliston; Dr. Balfour, Portobello; Dr. Stephenson, &c.

The following draft constitution was submitted to the meeting:—

1. *Name.*—That the name of the Society be “The Lothians' Medical Association.”

2. *Objects.*—That the general objects of the Association be to procure combination of action in all matters affecting the interests of the profession, and to promote a friendly feeling among the members, and that these be principally carried out by—*A.* Watching all bills that may be brought into Parliament in which the interests of the profession may be involved. *B.* The giving aid and support to any member who may be unjustly made the object of legal prosecution on the part of a patient. *C.* By decisions upon all questions of usage or courtesy in conducting medical practice, and arranging in all matters of dispute among members. *D.* By introducing various customs into practice which will be of benefit to medical men; such as making it be generally understood that midwifery, like consulting fees, be paid at the time, and coming to some definite arrangement to afford protection against the want of consideration on the part of the public in sending messages late in the day. *E.* By holding *conversazioni*, at which subjects of general importance to the profession may be discussed.

3. That all legally qualified practitioners be eligible for membership.

4. That the entrance fee be one guinea, with the annual subscription of five shillings.

5. That the affairs of the Society be conducted by a president, (two) vice-presidents, and (twelve) members of committee.

Dr. FOWLER moved that the Lothians' Medical Association be hereby constituted, and that the draft constitution now submitted by the Provisional Committee be generally approved. He congratulated the meeting that so far success had attended their efforts, and remarked that the manner in which the proposal had been taken up was due not to the agency of its original promoters, but to the claims of the good cause. With regard to the draft constitution now submitted, there were one or two points to which he would advert. He confessed that the idea of some united action with regard to the fees of the profession was that which had originally brought them together. In this respect the country practitioners were often very unfavourably circumstanced. Although there were many among the hinds and agricultural labourers who paid their medical fees, there were others who did not do so, and from which it was next to impossible to get any remuneration at all. He had not, in the space of twenty years, been able to get 20s. from that class in remuneration for his services, notwithstanding the families were earning in some cases 36s. a week. He thought the remedy for that state of things was for the practitioners to agree—and nothing could be done without their agreement—not to attend unless the hind gave a line to the practitioner, or to his master, saying he would allow the doctor's fee to remain in his master's hand at the term. With regard to the bothy people, something of the same kind might be done; and as to the other labourers—some of whom, when

their bill had run on for several years, betook themselves to another doctor to avoid the debt—(a laugh)—the practitioners might come to an understanding not to attend until the account of the previous medical attendant were settled. He would be the last to wish to harass any one, especially those who might be in straitened circumstances—for, as they all knew, there were many poor who were not on the poor's roll—and to such they would always be glad to give their services; but for those who were able to pay, but would not, he thought they were called upon to protect themselves. The only other point he would refer to was as regarded matters of medical etiquette. He thought that if one medical man felt himself aggrieved by another, the first thing he should do was to ask a friendly explanation, instead of taking his account of the matter from the patient. He thought such an association would be of great value in diffusing a kindly feeling among the medical profession, and in protecting their mutual interests (applause).

Dr. ANDREW WOOD seconded the motion. He said the profession might not have so much to complain of in the town as in the country; but if so, he felt it all the more their duty now to come forward and give their sympathy and help to their country brethren. They belonged to an anxious, laborious, responsible profession, and one that was often very badly required. There was no early closing movement for them, no Saturday half-holiday, no Sabbath rest, no assured rest even in bed at night. He thought, therefore, the profession required to be treated with all the more consideration and respect by the public. He believed that in past times much of the disparagement which had been thrown on the profession had arisen from the immense competition within it. It was because medical men had held themselves too cheap that they had been held so cheap by the public (hear, hear.) They had been held cheap by the poor-law authorities, and they had been badly treated by the army and navy medical services. He trusted there was a brighter day dawning for them; but if they would achieve freedom from these things they must achieve it for themselves. Every one knew that the standard of the profession had been greatly raised of late years, and it was impossible now for an illiterate man to enter the profession. It was impossible for men who had not gone through a high amount both of preliminary and professional education to enter the profession. In proportion, therefore, in which the standard of the profession was raised, the claims which the profession had on the public were raised. This association, would he thought, be instrumental in promoting these claims upon the public, as well as in forming a bond of union among themselves. It was also of vast consequence that they could bring such an organisation to bear on legislation with regard to the interests of the profession. If there were more associations and combinations of this kind they would not be offered such insults as vaccination bills, with a fee of 1s. 6d., or registration bills imposing on them the signature of certificates without remuneration. He held that in these matters the whole profession, both in town and country, was deeply interested, and that the formation of such associations would be attended with the best effect.

Professor BENNETT said he thought it was not only in the country but in the town that this question of remuneration was felt. It was not the hinds and bothy people only, but the public at large, that required enlightenment on this point. Circumstances were now greatly changed from what they were in former years. The prices of living had been greatly increased, yet the remuneration of medical men, instead of being increased, had rather diminished. He thought that one of the first duties of the committee should be to look into the question from a large point of view, and as affecting the whole country (hear, hear).

Dr. BONNAR, Cupar, suggested that the area of the Association should be altered so as to embrace Fifeshire, and, if necessary, also the north of the Tay.

The CHAIRMAN said there was nothing to prevent the

committee considering this question of extension, and there was no practical restriction upon the admission of members, but meantime he thought they should adopt the proposal in the draft constitution.

The SECRETARY said this question had been discussed in the acting committee. It was originally intended as a Mid-Lothian Association, but in consequence of representations coming from the other Lothians, it was resolved to adopt the wider title. It was even suggested that they should form a national association, but it was thought better to adopt a local basis in the first instance, but imposing no restriction on the admission of members.

Dr. ALEXANDER WOOD read a letter from Mr. Murray, Newcastle, suggesting that a universal association should be formed, to which local associations might be affiliated.

Dr. WARBURTON BEGBIE said that already there were medical associations of a similar kind in Forfarshire, in Aberdeenshire, and in the south of Scotland, and it would be rather trespassing on them to make this a national association.

The CHAIRMAN entirely agreed that it was desirable to make the operations of this body more extensive than only to embrace the Lothians; but he thought an excellent beginning would be made by adopting the proposed draft constitution. It might also be found that a large and comprehensive association would not work so well, and that members at a distance would cease to take interest in its business. It would be far better to form a series of local associations affiliated to a general body, each body acting independently in its own locality, but subordinated to a general principle.

The resolution was unanimously approved.

Dr. ALEXANDER WOOD moved that Dr. Christison be appointed president, and Sir J. Y. Simpson, Dr. Begbie, and Dr. Fowler, vice-presidents of the association. He said he need hardly impress on them the importance of union in the profession. They had hitherto left their interests to be attended to by others, and but for the intervention of the colleges there would have been no one to protect their interests. He did not believe the profession were generally aware of how much they owed the colleges, but for whose efforts much worse lunacy and vaccination bills would have been passed. If the colleges, which could only include a limited number of the profession, had done so much, what might not the whole profession do when it was organised, as it might be both here and throughout Scotland? The great thing to look for in the elevation of the profession was the diminution of its members (a laugh), and he was happy to say that the stringent examinations now imposed were reducing the numbers, and the consequence would be, that those who did practise would be of a higher grade, and their would be less competition and underselling among them; while what were denominated the rough-and-ready practitioners, who depended rather on mother-wit than on medical education would disappear. The poor-law boards and others, who were now grinding off the faces of the medical men, would be compelled to pay them adequately for the duties they were required to discharge.

Dr. BALFOUR seconded the motion, which was also carried.

The CHAIRMAN returned thanks for the compliment paid him. He remarked that notwithstanding the elevation of the professional standard the scale of remuneration had been allowed to sink, and it was now much lower than it had been in his young days. In these days medical men were scarcer and better paid, and it was only when they got more numerous that they felt any difficulty.

Dr. J. MATHEWS DUNCAN proposed the election of a committee of management, remarking that it would be a great advantage if, instead of rivalry, they promoted a spirit of goodwill and helpfulness among the profession. The following were the names of the committee proposed:—Professor MacLagan, Professor Bennett; Dr. Alexander Wood; Dr. Graham Weir, Dr. J. M. Duncan, Dr. Gillespie, Dr. Keiller, Dr. Sanders, Dr. T. A. G. Balfour;

Mr. W. S. Carmichael, Dr. Paterson, Leith; Dr. Balfour, Portobello; Dr. Bryce, Dalkeith; Dr. Bonthrou, West Linton; Dr. Gordon, Juniper Green; Dr. Main, Lasswade; Dr. Sheriff, Ratho; Dr. Smith, East Linton; Dr. Spence, Linlithgow; Dr. Wallace, Kirkliston; and Dr. Watson, Tranent.

The CHAIRMAN read letters of apology from Professor MacLagan and Sir J. Y. Simpson—the former suggesting the power of remit to an acting committee, and the latter pointing out that a sheriff officer got a larger fee for a statutory service than a medical practitioner.

It was resolved to remit to the committee to consider the expediency of enlarging the sphere of the association.

On the motion of Dr. BALFOUR, Portobello, seconded by Dr. GORDON, Juniper Green, Dr. P. H. Watson was appointed treasurer, and Dr. Stephenson was appointed secretary.

On the motion of Dr. ALEXANDER WOOD, a vote of thanks was given to Dr. Christison for presiding.

#### NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

ON Wednesday last the ceremony of opening the new National Hospital for the Paralyse and Epileptic, in Queen's-square, Bloomsbury, on the completion of the extensive and unique alterations, was performed by the Right Rev. the Lord Bishop of Oxford, in the presence of the Marchioness of Thomond, Lord and Lady Taunton, the Hon. Mrs. Lukin, Lady Smith, Miss Adelaide Henley, Miss Chandler (one of the founders of the institution), the Rev. John Back, rector of St. George's, Bloomsbury, and several friends of the institution.

The hospital was instituted in 1859, under the auspices of Mr. Alderman Wire, but it became necessary, in consequence of the increasing claims upon the institution, to take measures for enlarging it. When the hospital was closed twelve months ago for this necessary extension there were forty resident patients, who were dispatched to the country, and there are now 1200 out-patients, and a Samaritan society, managed by a committee of ladies, for assisting the more needy applicants with food, clothing, &c. A pension fund has also been formed, which yields sufficient funds for the granting of four pensions in perpetuity. The arrangements of the hospital in its present enlarged and improved form struck the visitors with surprise for their thorough efficiency and the admirable taste in which they are conceived. The architect has fused two houses into one with excellent judgment, both as regards the economy of space and the securing of complete ventilation; the furnishing of what are called the day rooms and the sleeping wards is in most pleasant relief to the ordinary gloom of hospital accommodation, and reflects the greatest credit on the good taste of the hon. secretary, Mr. Chandler; whilst the gymnasium and electrical room, the work of Mr. Radcliffe, the medical superintendent of the institution, is a model for imitation. It is difficult to convey a notion of the character and style of the house accommodation for the patients. Refined minds have been at work to select and dispose the furniture of this hospital, but the idea is expressed in the announcement of the committee of ladies when they acknowledge the generous sympathy which has enabled them "not only to provide every necessary for the sufferers, but to surround them with comforts, to soothe them with the sight of pleasant objects, and give them for the time a light and cheerful home."

MODE OF RESUSCITATING PATIENTS DYING FROM CHLOROFORM INHALATIONS.—M. Lefort stated at a late sitting of the Surgical Society of Paris, that he believed death to occur in these cases from syncope—i.e., want of cardiac contractions. He considers artificial respiration useful, because it forces blood from the lungs into the heart. A more efficacious measure, according to M. Lefort, is galvanism, with one pole placed along the spine and another on the epigastrium.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE.  
Medical Scholarship Examination.

TRINITY, 1866.

PROFESSOR McDOWEL.

1. Give a description of all the circumstances connected with the descent of the testicle.
2. Enumerate the structures which exist in the foetus, and either disappear or exist in a degenerated condition in the adult.
3. Enumerate the openings which are seen in the cavity of the tympanum.
4. Describe the dissection you would make to expose the terminal stage of the lingual artery.
5. The course, relations, and distribution of the temporo-auricular nerve?
6. Describe the epiphyses of the humerus, and state the periods at which they become consolidated with the shaft.
7. Enumerate the muscles which elevate and those which depress the acromion process.
8. Give a description of the thyroid veins.
9. Describe the popliteus muscle, and mention how it acts.
10. Enumerate the rotator muscles of the hip-joint, and assign their several actions.

CHEMISTRY.—DR. APJOHN.

1. Chlorine may be obtained by the action of muriatic acid on peroxide of manganese, bleaching salt of lime, chlora or bichromate of potassium; what is the reaction in each of these cases?
2. Explain the volumetric process used in the Pharmacopœia for determining the amount of iron present in a solution as a protosalt.
3. A wine-glass containing 230 grains of aqua lauro-cerasi was rendered alkaline by the addition of an excess of caustic potash, and to it then a standard solution of nitrate of silver was added until the precipitate which formed, when stirred, ceased to dissolve; the volumetric tube being now read, it was ascertained that thirty-five measures of the silver solution had been added; from these data deduce the percentage of hydrocyanic acid in the aqua lauro-cerasi.
4. There are but two ethers in the Pharmacopœia—a simple ether, and a compound ether; write the formula of each, and describe and explain the process by which they are obtained.
5. Describe the process by which calomel is made, and in particular the expedient by which it is obtained as a fine powder without resorting to trituration; state also how you would test it for corrosive sublimate.
6. How does Liebig determine by a volumetric process the quantity of chlorides in the urine, and the amount of its urea?
7. How would you make the analysis of blood so as to determine the amount of its fibrin and of its globules?
8. Write the formula of glycerine, and mention how it is insulated in the process of saponification; state also how it may be made artificially, and name the class of chemical bodies to which the fats should be referred.
9. What is the only proximate constituent of the blood in which iron is found; and how did Engelhardt show that the metal was present in the unoxidized condition?
10. Specify the colour tests for morphia, strychnia, and quinia.

DR. WRIGHT.

1. Compare any ordinary Dicotyledonous, with any ordinary Monocotyledonous Plant, as to their germination, stems, leaves, and flowers.
2. How is the terminal bud developed in the Ash, Elm, and Horse-chestnut?
3. Contrast the "pitcher" of *Nepenthes* with that of *Sarracenia*.
4. What are the effects of cultivation on the florets of a Composite Plant; and what as seen in the flowers of the *Ranunculaceæ* and *Rosaceæ*?
5. Describe an Anotropous and a Campylotropous Ovary.
6. Describe the fruit of the Walnut, Apple, and Date.
7. Describe the following confluent fruits:—*Syconus*, *Sorosis*, *Strobilus*, and *Galbulus*.
8. Give an instance of dehiscence taking place before the ripening of the seed.
9. Give a diagnosis of the Natural Order *Cucurbitaceæ*.
10. Write a detailed description of the Plant on the table.

## Notices to Correspondents.

*Dr. H.* is thanked for his suggestion.

*M.R.C.S.*—Your paper would not have the desired effect if published now.

*Medicus.*—In point of etiquette you were correct.

*F.R.S.*—The subject is a very delicate one to handle.

*Mr. John E.* shall have a private note.

*Dr. B.* shall be happy to receive the cases you mention.

*A. P.*—See MEDICAL PRESS AND CIRCULAR of March 28.

*Inquirer.*—"Public Opinion" is preferable.

*A Subscriber.*—Podophyllin, or vegetable calomel, as it is sometimes called, is the resinoid principle of *Podophyllum Peltatum*, or May-apple of North America. It is soluble in spirit, and partially so in ether. Wood and Bache describe podophyllin as an active and certain cathartic. In minute doses, frequently repeated, it is said to diminish the frequency of the pulse, and to relieve cough. It is employed in bilious fevers and hepatic congestions—with bitartrate of potash in dropsical rheumatism and scrofulous complaints; also in hæmoptysis, catarrh, and other pulmonary affections. Dose, from a quarter of a grain to one grain. The maximum dose should be given with caution. If an overdose is given, or it is taken by mistake, lactic acid should be freely administered. It is best administered in the form of a tincture, and with sugar of milk (sour milk or buttermilk). Podophyllum and its preparations possess great escharotic power.

*Mr. Griffin's* letter is inserted.

*P. S.*—The case is incorrectly reported in many particulars.

*Dr. Clarke, Dunmurry.*—The suggestion is a good one, and shall be followed up. We suspect it will prove that pledges in opposition are different from those in office.

*Dr. Clarke, Dunfanaghy.*—We have replied by private note.

## Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College, at a Meeting of the Court of Examiners on the 24th inst. :—

Ash, Robert Vacy, Stratton, Cornwall.  
Bell, John Hougham, Caroline-street, Bedford-square.  
Burton, Thomas Beard, Barbadoes, West Indies.  
Clark, Edward, M.D., Philadelphia.  
Coles, Charles George, Blenheim-crescent.  
De la Cour, George Francis, Chatham.  
Dodsworth, George Henry, Turnham-green.  
Eager, Reginald, Guildford.  
Evans, Owen, Panby Trefriw, Conway.  
Foxon, Foxon, Maddox-street, Hanover-square.  
Jackson, Frederick William, Broadstairs, Kent.  
Moore, George, Birmingham.  
Parks, John, Bury, Lancashire.  
Power, Frederick Douglas, Queen's-square, Bloomsbury.  
Pringle, James Marr, Tynemouth.  
Richardson, John Ashton, Hull.  
Ridout, Charles Lyon, Egham, Surrey.  
Robbs, Charles Henry Denny, Grantham, Lincolnshire.  
Trinnell, Edward Alfred, L.R.C.P.E., Lewisham-road.  
Turner, Thomas Aubrey, Wellington-square, Chelsea.  
Watson, Frederick Hastings, Norwich.  
Wilson, Henry Gratton, Great Malvern.

The following gentlemen were admitted Members on the 25th inst. :—

Bainbridge, George, Harrowgate.  
Cardozo, Frederick, Vinay, Madras.  
Chaldecott, Horace, Dorking, Surrey.  
Flint, Frederick, Canterbury.  
Hallowes, Adolphus Henry Blackwood, Canterbury.  
Hay, Thomas Bell, Caledonian-road.  
Lambert, Frederick William, Farsley, near Leeds.  
Langmore, John Wreford, Sussex-gardens, Hyde-park.  
Moon, Robert Charles, Brighton.  
Reilly, Maxwell James, Dublin.  
Salzmann, Frederick William, Brighton.  
Stedman, John, Islington.  
Taylor, Alfred Claude, Nottingham.  
Taylor, Frank, Askwith, Romsey, Hants.  
Vaudagne, Jean Baptiste Polyxen, Mauritius.  
Ward, John Lewis William, Cardiff, South Wales.  
Wheatcroft, Thomas Charles Croose, Cannock, Staffordshire.  
Williams, Evan Elias, Bangor, North Wales.  
Wilson, Thomas, Longford, Ireland.

At the meeting of the Court on the 24th instant Mr. George Bewsher Beale, of H.M.S. *Excellent*, and Mr. Robt. Longstaff Bett, of the Royal Naval Hospital, Hasler, passed the examinations for Naval Surgeons. These gentlemen had previously been admitted members of the College, their diplomas bearing date respectively January 7th, 1858, and April 15th, 1859.

## CONTRIBUTIONS TO CLINICAL SURGERY.

By WILLIAM HARGRAVE,

PROFESSOR OF SURGERY, ROYAL COLLEGE OF SURGEONS, IRELAND, SURGEON  
TO THE CITY OF DUBLIN HOSPITAL.EXCISION OF AN ATHEROMATOUS TUMOUR FROM THE  
FOREHEAD; WITH PATHOLOGICAL OBSERVATIONS  
ON ITS POSITION, AND THE RESULT OF IT.

I WAS consulted on the 27th June last by a professional friend as to the propriety of removing a small circumscribed tumour from the left side of the forehead of a young girl, aged seven and a half years. It was first noticed about a year previous to my seeing her, and was situated about a finger's breadth above the left superciliary ridge; it was slightly moveable, apparently deep-seated, resting upon the frontal bone. The ether spray was very well administered by Mr. F. McClean, producing but a *feeble* anæsthetic effect; the tumour was then extirpated, requiring a free dissection, and the division of all the coverings down to the bone, in which it was partially imbedded, and was removed in totality, with the capsule perfect; it was the size of a small flattened horse bean, of the atheromatous variety, and was completely covered by periosteum, to which it was adherent. On the removal of the tumour there was seen and felt an evident pit or cup formed on the frontal bone, admitting the end of the index finger. I mention this depression to assist in clearing up the difference of opinion which surgeons hold on this pathological question, as far as this single example will permit me to establish it.

In consequence of a case which I submitted to the Surgical Society of Ireland last February, of the removal of an atheromatous tumour from the back of a young lady's head, the size of a small walnut, which was easily enucleated, offering a strong contrast to the dissection requisite for the extirpation in the present case. The question was then raised, if the cranium was ever indented by these kind of tumours? Some of the members of the Society were for the affirmative; others of the contrary opinion. I remarked where the depression existed, if the tumour formed beneath the occipito-frontalis tendon and the periosteum, its presence caused the absorption of the bone, producing the pit or cup.

One of the members, actuated by great zeal for pathology, to clear up and decide this point, consulted some high surgical authorities in London, the museums in that city and in Edinburgh, also Cruveilhier of Paris; all admit such a result as the formation of these cups or pits is not very common from atheromatous tumours. This tumour rested upon the frontal bone, requiring a *free dissection* of all the superincumbent parts to detach it from its situation. The formation of the cup or pit in the cranium depends on the fact, whether the tumour is beneath or superficial to the periosteum. In this instance the tumour was not congenital. No doubt exists in my mind if permitted to remain in its situation, and increase in size, there would have been formed in the bone a cup or depression, with or without a lip or border, perhaps exposing the dura mater.

July 7th: A fortnight after the operation the wound healed, and a depression in the cicatrix indicated where the tumour was situated.

SUCCESSIVE FORMATIONS OF ABSCESSES AROUND THE  
KNEE-JOINT, COMPLICATED WITH SUBACUTE IN-  
FLAMMATION OF THE LATERAL LIGAMENTS.

Mary C—, æt. 22, admitted into the City of Dublin Hospital, May 7th, presenting all the symptoms of acute inflammation of the patellar bursa of the right knee, without any assignable cause, as is generally productive of this affection; the disease was of a week's duration; fluctuation at a depth from the surface, was evident. Means were adopted to favour the progressive course of the abscess to the surface; after two days it was freely opened by a perpendicular incision, and a large quantity of healthy pus was discharged from it. The ether spray was fully administered in this case, and did not come up to my expectations in alleviating pain; in fact, disappointment was the consequence of its application.

After opening this collection of matter, I anticipated the same course as I have experienced in many similarly situated purulent collections, that is to say, the discharge would gradually diminish, and a few days would bring round her convalescence, in which I was much deceived.

On the 18th another abscess formed on the external side of the knee, in the site of the external lateral ligament, attended with much pain. This collection called also for a free incision, giving exit to a large quantity of healthy pus.

On the 25th another large abscess formed on the internal side of the knee, over the internal lateral ligament, accompanied with intense pain, but as the matter communicated with the unopened incision, which was made for the patellar abscess, for which she was admitted, though suffering much, she resisted every proposal to have it opened; however, the pain became so intense, continuing for forty-eight hours, she asked for it to be opened. The ether spray was used, but certainly no alleviation to pain; through the wound I introduced my finger, which detected a large abscess, extending to the popliteal space, and a hand's breadth upwards above the centre of the knee; the internal lateral ligament was softened, shreddy, almost converted into a pulp, corroborating my opinion that these lateral abscesses were intimately connected with subacute inflammation of the ligaments on these aspects of the joint. The case then advanced rapidly to convalescence, and she was discharged from the hospital July 6th, one month from her admission.

Patrick D—, admitted June 19th, with acute patellar abscess of left knee, caused by kneeling upon a small angular pebble; one week's standing; evidently full of matter; it was freely opened, with a full discharge of matter. The case presented almost identical symptoms with the last, an abscess forming in relation to the external lateral ligament, attended with much pain referable to it, communicating with the patellar one. By judicious pressure and bandaging it was emptied through it and cured. Subsequent to this abscess a third one, attended with excruciating pain, formed over the internal lateral ligament, which the patient asked to be opened. He was suffering so much from it that the ether spray was used and disappointed me in mitigating the pain; the ligament was in the same condition as the internal one in the girl's knee. The course of the disease and the purulent formations were arrested, the man leaving the hospital one month and a few days from his admission.

These cases present a remarkable coincidence in their symptoms, progress, and termination, if not identity. The abscesses in both cases first forming in the patellar bursa; the origin of one seemed to be idiopathic, the other evidently due to an injury; then the formation of secondary abscesses on the sides of the joint in immediate relation to the lateral ligaments, attended with considerable pain; when opened, and that these structures could be examined, showing that they were affected with subacute inflammation, injuring seriously their textures; if permitted to proceed, causing their complete destruction, with great and permanent mischief to the joint. It is also worthy of

remark, the lateral abscesses in both of these cases observed the same origins; first on the patella; next in relation to the external lateral ligament; and last, in connexion with the internal lateral one.

CONTRAST BETWEEN CONGELATION BY ICE AND SALT AND BY THE ETHER SPRAY OF RICHARDSON.

To produce anæsthesia I have always in every instance, and these not a few, *but one*, in which I used ice and salt, succeeded in completely annihilating pain during the entire time of the operation. In my experience the *remarkable exceptional case* was in that of a gentleman who suffered from inflammation of the finger extending along the palmar aspect of it high into the palm of the hand. Such an operation, though of momentary performance, is always very painful; the ice and salt, preparatory to its being performed, was productive of *the most intense pain and suffering* that I ever witnessed, and compelled me to discontinue its application. Chloroform I would not administer. In all probability in this solitary instance the failure might have been due to its being applied to an intensely inflamed part.

From my experience of the ether spray I have come to the conclusion that it fails if applied to the integuments when in a state of high inflammation, as it did in both these patients; neither the woman nor the man was in any way relieved from the pain caused by the incisions; neither in the case of removing the atheromatous tumour did it lessen in any degree the pain in the cutaneous incision, though effectively applied by my young friend Mr. McClean. This mode of applying the anæsthetic agent is but a modification of Dr. Hardy's chloroform douche many years ago introduced into this city, which fell into unmerited neglect because not universally successful. Would chloroform mixed with anhydrous ether be more effective in relieving local pain? It would be advisable to test either of these anæsthetics singly or combined for this purpose.

SYMPTOMS ATTENDANT ON A LARGE QUANTITY OF LIQUOR POTASSÆ ACCIDENTALLY SWALLOWED: TREATMENT AND RAPID CONVALESCENCE.

James M. was admitted into the City of Dublin Hospital June 18, 1866; states that he had accidentally swallowed from two to three ounces of liquor potassæ, which happened in the following manner: He went into a druggist's shop in town to get an aperient draught, the boy attending him handed down a bottle containing liquor potassæ for one he thought containing water; the patient on attempting to swallow the draught, says that he felt a slight choking sensation. He then returned the draught to the boy, saying it was too strong, the boy immediately added more of the poison to the draught, telling the patient to drink it off; accordingly, he made a second attempt to swallow, and states that he got down about two or three ounces of the fluid, and there can be no doubt that at least a portion of it must have reached the stomach. The mistake was immediately detected and was treated by the chemist on the spot, by administering vinegar and water and sweet oil. He was then brought to the City of Dublin Hospital. On examination the entire mucous membrane of the mouth, tongue, fauces, deep into the pharynx, presented the appearance of the complete destruction of the epithelium, with intense inflammation of all these parts. The patient found great difficulty in swallowing whenever he attempted to do so, his body became doubled up with great pain, and he also complained of some pain in the epigastrium; I could trace the œsophagus from the pharynx with anatomical accuracy to the cardiac orifice of the stomach from the line and direction of his painful sensations, presenting a well-marked instance of œsophagitis. He complained of intense pain in the isthmus faucium, with a constant hawking of thin mucus tinged with blood.

℞ Aquæ fort ℥vi.; glycer. ℥iii.; acet. com. ℥iii.; gr. gargarisma utetur sæpe in die. He was supplied with a

weak mixture of common vinegar and water, also milk and water as drinks, ice was also supplied to him *ad libitum*; and six leeches to each external fauces, and a large warm poultice over the leech-bites when they fell off. To relieve the slight pain of the epigastrium a mustard poultice was applied.

Two p.m.: These measures have afforded some relief, though the inflammation has slightly increased.

Ten p.m.: Deglutition less difficult and painful, inflammation also diminishing, and expresses himself much relieved.

June 19th: Has lost all the anxiety of countenance so marked yesterday. Ordered a draught of castor oil with trœ opium, and barley water as a drink.

20th: Improving; the aperient of yesterday was now assisted by an enema purgans. Infusion of linseed with milk as a drink.

As some vestiges of inflammation still existed in the internal fauces, a small blister was applied on each side. The enema has acted most effectively with great relief to his organism.

The case improved daily, he was ordered the decoction of slippery elm as a drink, the mist. creasote (P.B.), with glycerine ℥i. 4tis horis, and left the hospital convalescent June 22, being four days under treatment; he attended at the dispensary till the end of the month, finding himself well and a complete recovery.

What was most remarkable in this case was the intense pain referred to the fauces, the inflammation threatening to extend down the pharynx, and implicating the larynx, which was prevented by the prompt measures successfully adopted to check it. The mistake was promptly met by the druggist's shopman. Could not these accidents be guarded against by having a very visible mark on the bottles containing such dangerous compounds? How many druggists have adopted the simple means of obviating the dangers of nitro-glycerine?—Vide MEDICAL PRESS AND CIRCULAR, vol. i., p. 655.

FORMATION OF AN ARTIFICIAL DELTOID MUSCLE FOR THE TREATMENT OF LUXATIONS OF THE SCAPULAR EXTREMITY OF THE CLAVICLE, ILLUSTRATED BY A SUCCESSFUL CASE.

Mary Bergin, æt. 40, applied at the dispensary of the City of Dublin Hospital, June 24, 1866, presenting all the symptoms of a well-marked luxation of the external end of the clavicle of the right side, riding upon the corresponding acromion scapulæ, the result of a fall the previous evening on the shoulder. She suffered much pain, and the arm hung useless by her side.

*Treatment*.—A pad was applied in the axilla, and the arm supported in a sling. The following means were adopted by which an *artificial deltoïd* was made:—Broad and long strips of adhesive plaster were extended, one from the side of the neck down along the great anterior division of the deltoïd muscle, another from the base of the scapula along the supra-spinatus fossa over the acromial end of the scapulæ, covering the middle portion of the deltoïd below its insertion to the humerus; while the third broad slip was applied from the base of the scapulæ, covering the posterior and third great division of the same muscle. The intervals in the spaces between the broad slips were covered and supported by narrower and longer slips of adhesive plaster. The patient expressed much ease, freedom from pain, and support to the limb after this very simple bandage.

July 14th: Much use of her arm; the *artificial deltoïd* continued.

July 21st: Much improved; the *artificial deltoïd* continued. Treatment recommended for this accident is as follows: From the decided benefit derived from this simple and efficient apparatus, which gave this woman the almost complete use of her arm with the deformity much diminished in four weeks, no other retaining bandage being used, as she was impatient of restraint.

The plan to be adopted is, in the first instance, to place

well up into the axilla the wedged-shaped compress, as is used in fractures of the clavicle, well supported in it by broad tapes sewn to it at each superior angle, and carried across to the opposite side of the neck and secured, the inferior portion of it supported against the side of the thorax by a few turns of a single headed roller. The humerus is then applied close to the trunk and fixed in position by a roller carried *first behind it to prevent the arm falling forward across the chest*, the elbow to be supported by a few turns of the same bandage, and the hand confined by it to the thorax above the mamma. The next step in remedying the deformity is the application of the adhesive plaster, as already indicated, forming what I term an—*artificial deltoïd*.

This apparatus, carefully applied, will afford every relief to the patient, at the same time giving him the conviction that the shoulder has regained its normal strength.

#### NOTES OF A CASE

IN WHICH

#### EVULSION OF THE UMBILICAL CORD OCCURRED AT BIRTH.

EVULSION OF UMBILICAL CORD AND SYNCOPE OF INFANT AT THE BIRTH.

By Dr. G. de GORREQUER GRIFFITH,

PHYSICIAN TO THE HOSPITAL FOR WOMEN AND CHILDREN; PHYSICIAN-ACCOCHEUR TO ST. SAUVOUR'S MATERNITY; AND LATELY HOUSE-SURGEON TO THE LONDON SURGICAL HOME.

ON Sunday evening, July 8th, I was summoned to attend Mrs. —, who was taken in labour with her first child. I attended almost immediately, and on my arrival I was told that they did not think I should be required just yet, as she had been in pain only for the last two hours. I forthwith entered her room, at the very moment I did so she had a strong bearing-down pain, and I told her that she had better lie down as soon as the pain was over. While she was yet in pain she attempted to get on the bed, but as she made the effort she called out that the child was in the world, and before I could endeavour to catch it, the little thing fell upon its head with some force, and rolled upon the floor. I noticed that the child was quite livid, that the cord had been torn out from the abdomen, and that the child was apparently lifeless. The blood spouted out from the umbilical aperture, and before I could render any assistance some little quantity was lost. The child seemed to be in a state of syncope, very soon lost its livid hue, and became all over deadly pale. As quickly as I could I seized the integument surrounding the umbilical aperture (there was not a vestige of the cord), and tied it as tightly as I could. Fortunately the state of syncope in which the child lay enabled me to apply the ligature tightly, no pain being felt, and so effectually that it did not slip off, nor was afterwards disturbed when the child began to cry and to move. No ill effect obtained to the mother, and the placenta was easily removed.

As the case I have described is of extreme rarity, and as I do not know of even one similar to it being on record, I have thought it fit to bring forward.

The treatment of this case was extremely simple—first, because of the syncope into which the child fell; and, secondly, because of the lax condition of the abdominal integuments, which allowed of their being pinched up in order to be tied.

I need not here dwell upon the difficulty usually attendant upon ligaturing the integuments surrounding the umbilical aperture in the abdomen when the accident of which I speak has occurred, inasmuch as it must be impressed upon the mind of each of those practitioners who have been consulted in such circumstances. Syncope in infants is a rare occurrence—I mean true syncope, occurring from concussion of the brain, and not merely that imperfect state of animation which so often obtains at

birth, and is manifested by feeble action of the heart and an uncertain state of the entire system, which, as it were, oscillates between life and death.

A condition of coma or semi-coma is by no means so infrequent. One case of complete coma occurring in the infant at birth, as the result of compression during labour, and lasting for two days, then terminating in death, has recently come under my notice.

"Only in one instance," says Dr. Underwood, "have I seen anything at all resembling the true syncope after the living powers have once prevailed. In this case the child was born at the instant its mother was moving from her chair into her bed, and, in consequence, fell with violence on the floor; it, however, soon cried, and did not appear to be very materially injured; but a day or two afterwards it fell into a strange, languid state; it revived, but at intervals sank into its former languor, breathed very faintly, and died about the sixth day." Mr. Hey of Leeds, communicated to Dr. Underwood the notes of a case of "an infant, which, born at full time, lay moaning and languid for four or five hours, and was then seized with a fainting fit, in which it continued for half an hour. It had ceased to breathe, except now and then giving a gasp or sob, and was as pale as a corpse. There was, however, a sensible pulsation of the heart, though feeble and slow; but whether the circulation had been kept up all the time previous to his visit could not be ascertained." The child was revived by the use of stimulants, but "had three other similar attacks in the course of the day, though it had slept composedly between whiles, and sucked at the breast. It had seven more fainting fits in the night. The infant became a very healthy child."

On the fourth day of the existence of my patient that portion of the integument outside the ligature showed signs of vitality having ceased in it, and on the fifth day it came away, leaving a round, evenly-cut wound in the skin of the abdomen, surrounded by a ring of inflammatory redness.

During all the time of my attendance (nine days) the child did well, had no untoward symptom, and the wound was healing rapidly when I took my departure.

9, Lupus-street, London, S.W.

#### THE PERFORATOR.

By D. B. O'FLYNN, A.M., M.D.

ONE of the most painful positions in which a surgeon can be placed is where he is reduced to the alternative of destroying one human life to save another, and though it is the rule in British midwifery not to resort to so dreadful an expedient until the fœtus has expired, still we are sometimes compelled to destroy a living child when the mother's life is endangered by exhaustion from protracted labour, consequent on an impacted or ossified or hydrocephalic head, or from a deformed pelvis. Apart from the feeling, that we deliberately kill the child, the lacerations so often inflicted on the mother by the careless use of instruments, or by spiculæ of bone, and the difficulties encountered in effecting delivery after perforation will, I trust, be a sufficient excuse for placing before the profession any point which is calculated to lessen the difficulties of the operation and facilitate our means of delivery.

The instruments usually enumerated as necessary for the operation of craniotomy are the perforator, crotchet, blunt-hook, and craniotomy forceps. The use of the first is easy enough, as we have merely to apply the instrument to the most dependent part of the head, when a little manipulation will cause it to enter the skull; but it is in extracting the fœtus after perforation that all our difficulties commence, and in performing this part of the operation an hour or more has frequently been spent in futile efforts at extraction, while the woman, dispirited and exhausted, has to be plied with stimulants, and the operator himself is often greatly fatigued. When the pressure of the

head is very great, it sometimes happens that after the perforator is withdrawn the bones so overlap each other that the opening is again closed, and it becomes difficult to introduce the crotchet, and when introduced, it generally breaks the bones, and may even lacerate the vagina. In such cases the blunt hook is found equally unmanageable, and the craniotomy forceps so crushes the bones, that the presenting part of the head may be torn into fragments, without being moved from its position. Under those circumstances, when it has been found impossible to deliver with instruments, operators have had recourse to version; and Ramsbotham tells us that on two occasions he destroyed the skull so entirely that both the orbits and the foramen magnum had given away, and he eventually delivered by turning. I had a somewhat similar case myself, which I reported in THE MEDICAL PRESS for May, 1861. Dr. Mackenzie ("Obstetrical Transactions" vol. i.) relates a case in which after using the crotchet for two hours, he delivered by turning, and the woman died of shock; he, however, only recommends it when the head is above the brim, and he says it would be unwarrantable when the head is within the pelvis. I had a case recently requiring craniotomy, in which I adopted a mode of delivery suggested to me by Dr. McEvers of Cork, and which is calculated to obviate all those difficulties.

J. L., in her fourth confinement, when seen by me had been complaining since the previous day. On examination I found the membranes ruptured, the head high above the brim, and inefficient uterine action. I ordered warm drinks, and gave a drachm of tinct. secal. cornut.; after a time the head descended and occupied the brim, where it became impacted, and I now ascertained the position to be, face to the promontory of the sacrum, and occiput to the symphysis pubis. I applied the forceps, but the blades slipped off. I then altered the position, inclining the face a little to the right ilium, and again applied the instrument, but all my efforts at delivery were unavailing, and it became evident that perforation was inevitable; but knowing the difficulties I would meet in extracting the fœtus, with the head high up, and the uterus not acting, I shrunk from doing the operation until Dr. McEvers' suggestion occurred to me, when I proceeded to deliver in the following way:—Having locked the forceps, I got an assistant to hold them; I then introduced the perforator between the blades, and let out some cerebral matter. Having withdrawn the perforator, I took the forceps from the assistant, and extracted the child with comparative ease, with safety to the mother, and without meeting any of those difficulties, whose harrowing details render the accounts of this operation so repugnant to our feelings of humanity. This mode of delivery by the forceps and perforator (taking care to *lock the forceps before perforating*), may be substituted for delivery with the crotchet, unless in those very rare cases of extremely deformed pelvis, where it would be impossible to introduce a forceps.

Reviewing the foregoing facts, we find that there are three modes of completing delivery after perforation—viz.: (1) the crotchet and blunt hook; (2) version; (3) the forceps. If we compare those we must, I think, conclude that the last is the safest and the easiest; when compared with the crotchet and blunt hook, it is found less liable to lose its hold, and less likely to lacerate the soft parts of the mother, it compresses the head into a smaller compass, without loosening any spiculae of bone, and by affording a firmer purchase enables the operator to deliver in a short time, and with less trouble to himself; it is a compressor, an extractor, and an excitor of uterine action. It should therefore be substituted for those instruments in all craniotomy cases where the capacity of the pelvis will admit. Its advantages over version are no less striking, it causes less shock to the mother's system, and is less likely to be followed by hysteritis; it is also more practicable, for it is admissible when the head is within the pelvis, in which case version would be unwarrantable. Having proved the superiority of delivery by the forceps over the modes usually adopted, the point to which I would direct particular

attention is to apply the forceps before perforating; if we delay its application until after perforating, when the solidity of the head is diminished, we will not be able to get so good a purchase, and accordingly, I would recommend that the blades be kept carefully adjusted until the perforator is withdrawn. When the head is opened it yields readily to pressure, and becomes elongated, and I may here observe that it is better not to let out much cerebral matter, for if the bones collapse, the instrument will slip off, having no resisting medium to grasp. I have heard it objected to this, that the child may be born alive, but admitting the possibility of such an occurrence, it is trifling, when compared with the suffering that women are compelled to endure under the ordinary modes of delivery.

Of all cases of instrumental labour, craniotomy cases are by far the most fatal; according to Tyler Smith the maternal mortality in such cases is 1 in 5, whereas after the use of the forceps it is less than 1 in 20. According to Sinclair and Johnson, the mortality to mothers in the former cases is 1 in 10.5, and in the latter 1 in 56; and the mortality to mothers in turning is stated to be 1 in 15. By adopting the method suggested in this paper, it appears to me that we may reduce this high rate of mortality at least one-third; and by adding another to the many triumphs of modern midwifery, save parturient women much of the pain and misery attending difficult labour.

There is nothing new under the sun, and probably the proceeding now recommended may have occurred to many accoucheurs; but as far as I can learn it has never been published, while all the minutiae of delivery with the crotchet, blunt hook, craniotomy forceps, osteotomist, and version, have been repeated *ad nauseam*; doubtless it may appear too obvious and simple for recital, but its simplicity constitutes its best claim to consideration.

Carrignavar, 2nd August, 1866.

#### LATEST NEWS OF CHOLERA IN LONDON.

TUESDAY MORNING, AUGUST 7TH.

LAST Saturday an influential deputation from the London Hospital was received by the Lord Mayor. From what transpired we learn that the whole of one floor of the hospital has been given up for cholera patients. From the 10th July to the 4th of August the number of patients admitted into these wards had been 365, of whom 299 were suffering from cholera, and 66 from diarrhoea. Of these 97 have recovered, being 48 from cholera and 49 from diarrhoea. 166 have died, 158 from cholera, and the other 8 from diarrhoea. 102 remained in the wards, 93 of whom suffered from cholera, and 9 from diarrhoea. Besides these admitted, 6251 persons have received relief as out-patients. The extra cost incurred has compelled the hospital to make a special appeal to the public for pecuniary aid, and this is being liberally responded to.

It is with pleasure we announce that no case of cholera has occurred in Dublin since our last. The disease has, through the energetic action of the authorities, been happily confined to one house, from which four persons have died.

A City Cholera Relief Fund has been organised, and will distribute money grants, wine, brandy, and clothing, to dispensaries, visiting associations, and other charitable institutions, as well as to the clergy of all demonstrations in the districts where the epidemic is prevalent.

A Special Cholera Fund is also commenced by the Bishop of London. To this the Queen has sent a cheque for £500.

On the suggestion of Mrs. Gladstone, a Children's Home is being formed for the reception of the orphans whose parents have perished in the epidemic.

From Liverpool the accounts are more favourable. Both deaths and admissions to the cholera wards continue at the lowest average since the commencement of the epidemic.

The accounts from Winsford are also less alarming. There have been no cases in South Wales, except in Llanelly.

## Hospital Reports.

### GUY'S HOSPITAL.

Under the care of Mr. BRYANT.

#### STONE IN THE BLADDER OF A FEMALE CHILD—ITS SUCCESSFUL REMOVAL BY LITHOTRITY.

CASES of stone in the bladder of the female are worthy of record, not only on account of their rarity, but also on account of the doubt that still exists as to the most approved mode of their removal. To those interested in this subject we would refer them to a paper by Mr. Thomas Bryant published in the *Med. Chir. Trans.* of 1864, for they will there find the results of the different plans of treatment which have been adopted carefully analyzed, and some interesting cases recorded in which large calculi have been successfully removed by rapid dilatation of the urethra; they will also find some well-considered practical conclusions as to the treatment of those cases. In the following example the treatment of the case was determined by the size of the calculus—for a stone one inch in diameter was looked upon as too large to remove by dilatation.

Case 1.—Susan W., aged 5 years, was admitted into Guy's Hospital, under the care of Mr. Bryant, on March 22, 1866. She had had symptoms of stone for several years. On March 28th the calculus was measured with a lithotrite, and as it appeared to be an inch in diameter it was at once crushed. A second operation was performed on March 31st, and a rapid cure followed. The stone was composed of lithic acid. No water was injected into the bladder in this case, enough urine existing to allow of all necessary manipulation.

#### LARGE STONE IN THE BLADDER OF A MALE; LITHOTRITY AND CURE IN ONE SITTING.

Case 2.—R. C., æt. 38, a healthy man, came under Mr Bryant's care in August, 1863, with symptoms of stone of three years' standing and great irritability of bladder. He was unable to hold his urine night or day for more than an hour. On admission a stone was at once detected, and by the administration of alkalies, &c., he was soon enabled to retain his water for one hour and a half, and could hold enough to permit the operation of lithotritry being performed. This was accordingly done on the 26th of September. The stone measured with the lithotrite an inch and a quarter, and was readily broken; it was caught and crushed twenty times. On the 27th of September the man had passed a quantity of fragments and much sand, but what was of great interest referred to the bladder, for its irritability had much subsided, and he was able the night of the operation and the next day to retain his urine for three hours and a half, instead of the one hour and a half, which was the extreme limit before the stone was crushed. The whole of the *débris* came away after this first sitting, the man leaving the hospital well in October. The two chief points of interest in this case are:—First, that so large a calculus was removed by one operation; and secondly, that the irritability of bladder was at once removed by the crushing of the stone.

#### LITHOTRITY IN A YOUNG MAN, AGED 18; LARGE CALCULUS.

Case 3.—John B., æt. 18, was admitted into Guy's Hospital, under the care of Mr. Bryant, in May, 1866. He was apparently a healthy man, and had resided in the country. He had had symptoms of stone nearly all his life. He had never had his bladder examined. On the passage of a sound a large calculus was at once detected. The lithotrite gave its size as an inch and a half in diameter.

On May 9th lithotritry was performed, the man lying in bed with the buttocks well raised. His urine had been

retained for several hours. The stone was crushed freely, and the man bore the operation well.

On May 16th the operation was repeated, the man having passed abundant *débris* of a lithic acid calculus since the first sitting. On this occasion, also, the stone was fully broken up, having measured again an inch and a half, the same measurement as given on the first occasion; it was consequently believed that it must have been caught at first in its short diameter.

On this occasion Mr. Bryant employed the instrument which was suggested and made by Mr. Clover of London, and subsequently modified by Mr. Maunder, for the removal of the *débris* after the operation, and was most pleased with its success, for he removed a quantity of broken fragments, indeed, as it subsequently proved, all that existed.

On May 26th a third sitting was given, and the stone well broken, the fragments being again removed with rapidity and ease by Clover's syringe and catheter.

The fourth and last operation was performed on June 2nd, with an equally good result. The calculus was then finally crushed, and the whole of the broken fragments removed. The man left the hospital at the end of June quite well.

This case is a good one as illustrating the full benefit of lithotritry, for the stone was a very large one. It will have been observed that Mr. Bryant did not inject the bladder prior to the operation, but was satisfied by the patient retaining his urine for as long a period as he was able before it was commenced—this practice being his usual one. The successful application of Mr. Clover's instrument for the removal of the *débris* was well exemplified, for as Mr. Bryant states, if the stone had been only of moderate size, it could have been broken up and removed at one sitting.

### RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

#### DR. LYONS'S CLINIQUE.

##### PHTHISIS SENILIS: PERICARDITIS: AUTOPSY.

J. M., aged 60, a patient whose case has already been referred to as illustrating chronic pericardial murmur, with permanent high pulse, was readmitted to the Whitworth Hospital at the end of June. He had been by occupation a stableman, and had long suffered from cough and debility, but worked on until some time prior to March last, when he was received into hospital labouring under phlegmonoid erysipelas of both lower extremities. Free incision was practised on repeated occasions for the evacuation of several purulent dépôts in both legs, and a general tonic and supporting plan of treatment was adopted, under which, after several weeks, he began to convalesce, when suddenly, at night, he coughed up a large quantity, considerably over a pint, of mixed pus and blood. Purulent and muco-purulent expectoration persisted henceforward, but he gradually acquired a considerable amount of strength; the appetite was pretty good, and he expressed himself in all respects greatly improved in condition. A striking feature about his case, however, was the persistence of an extremely high pulse, generally 140 per minute, occasionally as much as 144, and at very rare intervals only, falling to 130. Atheromatous bead-like particles were distinctly to be felt through about two inches in extent of the right radial artery, and a pointed spicular nodule was very manifest in the left. On careful examination slight general dulness was observable over the anterior surface of the left side of the chest, and on applying the stethoscope, crepitus and muco-crepitus were generally audible in this region, and under the clavicle gurgillement was occasionally discernible, but never for any lengthened period. When the heart was carefully explored well-marked double-friction sound, limited to an area of some couple of inches square, was heard over the body of the

ventricles; it became intensified when pressure was made with the instrument over the part examined; it varied very slightly from day to day, and with these characters, in conjunction with the rapid pulse above referred to, continued as a persistent phenomenon of the case for a period of nearly four months. After a sojourn of about two months in the institution, the patient being up daily and able to walk about the grounds, left hospital at his own desire, and contrary to the wishes and advice of the clinical physician; but notwithstanding the high rate of the pulse, and the local phenomena in the thorax, the patient felt himself and appeared to be in far better case and condition than the physical signs of disease which he presented warranted the observant physician in declaring him to be.

After an interval of about one month, the patient again sought admission to hospital, much deteriorated in strength and appearance, and having found the evidences of returning health and strength on which he too confidently relied but too fallacious. The pulse was now found to range between 130 and 140; a tracing of it by the sphygmoscope was accurately taken; cough and expectoration were more constant and distressing; the signs of tubercular lesion throughout the left lung were still more fully evidenced; the double-friction sound was still well marked over the ventricles, in the same area as formerly; some dropsical swelling of the legs was present; and it was soon evident that effusion, though as yet of slight amount, had taken place into the cavity of the abdomen.

The further progress of this remarkable case does not need daily comment; his strength gradually failed; the appetite languished; in attempting to get up at night he sustained a heavy fall which severely shook his now shattered and enfeebled frame, and from the effects of which he never quite rallied; the cardiac friction sounds now became more and more obscure, while the tubercular lesion advanced rapidly in the lung. Finally, he died on July 31st, about five months from the date of his first reception into hospital.

On post-mortem examination, the left lung was found far advanced in a condition of almost universal tubercularization; a vomica about the size of a small orange was found at the apex, and numerous smaller cavities were observable here and there throughout the organ. Through the right lung a few scattered deposits of tubercle of inconsiderable size were found, but in none was there any approach to softening.

On attempting to open the pericardium, it was found to be universally adherent to the surface of the heart and great vessels by the intermedium of a fine areolar-spaced tissue, evidently of recent formation, and with a little care the parietal layer could be separated from that covering the heart. This organ was enlarged, soft, flabby, and in a state of partial adipose degeneration.

Behind the heart and pericardium, and somewhat to the right, and lying on the diaphragm, was found a cyst, with thin and almost transparent walls, containing about half a pint of clear serous fluid. On the surface of the sac were scattered here and there numerous minute tubercular granules, about the size of a pin's head. This curious cyst seemed to take an origin quite independent of the lung or pericardium. The kidneys, in other respects healthy, presented several cysts; the right contained one capable of holding a walnut, with three or four others of less size; while the left exhibited a few of minute dimensions.

In summing up his observations on this interesting and instructive case, Dr. Lyons called attention to the prolonged state of pericardial inflammation, evidenced by well-marked friction continued for months, and ceasing only a short time before death, when adhesion took place. It was open to surmise during life that the cause of the pericardial friction was either a tuberculous or an atheromatous state of the investing membrane of the heart, and in support of one and the other opinion, the coexisting state of the lung and of the radial arteries might be respectively cited. Post-mortem examination, while it verified

the diagnosis made during life, proved that the form of pericarditis was that with ordinary lymph exudation eventuating in one of its natural terminations, that by universal adhesion between the heart and pericardium.

The cyst which lay behind, and partly to the right of the pericardium, next demands consideration. Its deep-seated position, and the thin expanse of fluid which it in all probability presented during life, when subjected to the pressure of the heart, fully distended lung, and other contiguous parts, placed it out of the reach of diagnosis. But should such a cyst happen to lie in front of the heart, and thus receive a wave-like pulsation at each cardiac systole, the existence of hydrops pericardii might be not unreasonably concluded, and if an operative procedure were had recourse to, and the fluid were evacuated, a still further confirmation of an essentially erroneous conclusion would appear to be irresistible. In considering the question of tapping the pericardium, the possible occurrence of such a cyst requires to be borne in mind as a source of error in diagnosis and complication, if not impediment, in the performance of the operation.

#### RENAL DISEASE: BRONCHIAL PHTHISIS: AUTOPSY.

J. M., aged 40, a seamstress, unmarried, was admitted into the Whitworth Hospital, labouring under general dropsy, with albuminous urine of specific gravity 1010. She had a peculiar cachectic waxy appearance, and suffered from headache, nausea, with frequent rejection of food, and occasional vomiting of dark-coloured grumous matter. Besides the foregoing symptoms she experienced much distress in breathing, complained of pain and soreness in the throat, referred to the region of the thyroid cartilage, and she occasionally experienced difficulty in swallowing. On examining the throat much tumefaction was observable in the mesian line, corresponding to the thyroid body, and well marked "tippet-like" swelling was noticeable round the neck. The thyroid veins were found to be enormously enlarged, and could be seen and felt of the size of goose-quills, crossing the inferior portions of the sternomastoid muscles on either side. Marked stridor was audible from time to time, as the examiner stood by the bed-side, and on applying the stethoscope, very loud and hoarse respiration was to be heard over both lungs both before and behind. There was much variation in the intensity of the stridor and in the loudness of the respiratory sounds at different periods. The radial arteries and the pupils were carefully and repeatedly examined, but with negative results as to the effects of unilateral pressure on vessels or nerves. It was obvious that deep-seated constriction was being exercised on the trachea, as the result of eccentric pressure (see Lyons's "Essay on Aneurism," *Dub. Quart. Jour.*, May, 1850), but in the absence of "intrinsic" phenomena the nature of the tumour or other compressing agency was open to speculation, but did not admit of absolute diagnosis. The peculiar waxy lemon yellow of the face and surface generally would go far to warrant the surmise of the cancerous nature of such tumour, but this opinion was not entertained; and against the suspicion of aneurism could be urged that a tumour of sufficient size to compress the trachea to such a remarkable degree, should not ere now have reached sufficient dimensions, to have given some evidence of its presence by dulness on percussion, erosion of parts in its neighbourhood, or phenomena of pulsation and sound.

Treatment proved of little avail in this case; the patient retrograded day by day; cough, dyspnoea, incapacity to lie down, sleeplessness, all became more urgent, and after much and protracted suffering the patient finally sank on the 31st ult.

On post-mortem examination, puckered cicatrices, with calcareous deposit, the evidence of old tubercular lesions, were found in both lungs. Numerous enlarged and tuberculated bronchial glands lay upon the trachea, extending into the neck on the one hand, and far on into the right lung, along the divisions of the bronchus. A clustered mass of these glands was firmly attached to the right side

of the trachea, just above its bifurcation, and imbedded in this mass, and completely inseparable from it, lay the right pneumogastric nerve, itself much thickened and enlarged. In the same cluster some two or three of the glands were filled with soft semi-purulent tubercular matter, and in the root of the right lung great numbers of the glands were in a similar condition. In the abdominal cavity the liver presented three very large, deeply-indented, and very hard cartilaginous cicatrices of old abscesses; it was likewise studded with numerous minute pea-like abscesses, filled with recent pus. The kidneys were very firm, pale in colour, and weighed respectively three and a half and four ounces, and were in an extreme condition of dense waxy degeneration.

## Foreign Medical Literature.

### M. BOUCHUT ON THE DIAGNOSIS OF SYMPTOMATIC AND ESSENTIAL PARALYSIS OF THE SIXTH PAIR OF NERVES, BY MEANS OF THE OPHTHALMOSCOPE.

Translated from *L'Union Médicale*, July 3rd, 1866.

By BALTHAZAR W. FOSTER, M.D., F.L.S.,

PROFESSOR OF CLINICAL MEDICINE IN QUEEN'S COLLEGE, AND PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

PARALYSIS of the sixth pair, or external motor nerve of the eye, shows itself sometimes as an isolated and entirely local malady, and thus forms a true morbid entity. Under this head it figures in all our classifications of disease, and it has been the object of some special researches by MM. Badin d'Hurtebise, Bégran, Roux, Jobert, and others. Notwithstanding all these works, it is often very difficult to diagnose the cause of this paralysis. It is even sometimes surrounded with so much obscurity that one hesitates before deciding whether the paralysis depends on a simple functional disorder of the sixth nerve, on muscular contraction of the right internal rectus, and hypermetropia, or whether it results from an organic lesion of the nerves and the nervous centres. It is with the object of perfecting this diagnosis that I publish the results with which the ophthalmoscope has furnished me—results which have occurred in addition to those which my "Treatise on the Use of the Ophthalmoscope, applied to the Diagnosis of Diseases of the Nervous System,"\* already contains.

At the Hospital for Sick Children, four children have this year been brought under my care for paralysis of the right external rectus, and at the same time they have had internal strabismus and diplopia. The first case without any other symptom, while in the second there were vomiting, constipation, some involuntary movement of the limbs, and feebleness of intellect; neither of them appeared to have any weakness of vision, and the diplopia disappeared before the strabismus had altogether ceased. The third and fourth cases had at first sudden convulsions, followed by convergent strabismus, which has not disappeared. In doubt whether the paralysis of the external motor nerve of the eye was symptomatic of a lesion of the nerves and the nervous centres, or whether, on the contrary, it was idiopathic and spontaneous, I had recourse to the ophthalmoscope, and this instrument having enabled me to detect the existence of considerable disease of the optic

nerve and the retina, which I am about to describe, it became evident that the paralysis was symptomatic. Finally, here are the cases of these four patients, and I shall append some remarks which will serve as a *résumé*.\*

*Case 1.*—*Lead colic, followed by cerebral complications and paralysis of the sixth pair: Ophthalmoscopy: Improvement.*—Malassaqui (Mariette), *ætat.* 14, was admitted December 13th, 1865, into St. Catherine's ward, at the Hospital for Sick Children. This child was employed in a type-foundry, situated in the Rue de Madame. She had suffered for some time past from alternations of constipation and diarrhœa, with colicky pains more or less severe. When admitted into the hospital she still had these pains, and for two or three days slight diarrhœa. Her appearance was healthy; she was small but strong, and of a tolerably good complexion; her lower gums presented a well-marked darkish lead line; stomach flattened, indolent; no gurgling; appetite good; no feverish symptoms. Under the influence of bismuth the diarrhœa was rapidly arrested, but after ten days she was seized with feverishness, cephalalgia, vomiting, and pains in the right lumbar region. Simple erythematous tonsillitis was developed, which lasted three days, when she was well, with exception of pains in the head. The child was then taken suddenly with slight diplopia, and with convergent strabismus, on the right side, but without any weakness of sight. She appeared a little swollen, and when she was told to laugh, there seemed to be a slight muscular feebleness on the left side of the face. She had no difficulty in speaking or walking; she used both hands with equal strength, and had no feeling of numbness or anæsthesia; appetite good; no vomiting; bowels moved daily; sleeps well; no dreams or hallucinations, and no fever; both pupils are equally dilated and contractile, and after dilating them with belladonna, the lesions of both eyes were found by the ophthalmoscope to be nearly similar; on the right side the papilla was completely veiled by a general hyperæmia, and its position was only recognized by the vessels which entered and left it. These vessels were tortuous and irregular. The circulation in the veins was interrupted by clots of blood. There were small hæmorrhages on the edges, and at the superior part two white, fatty, albuminous spots. She was discharged on Jan. 21st, when she had no longer any strabismus, the state of the fundus oculi was the same, and some fresh hæmorrhages had taken place in the left eye. For several days a boil situated on the upper part of the forehead, on the right side, had caused œdema of the eyelids; no albumen in the urine. At the end of two months and a half I saw this child again in her workshop; she was entirely cured. No appreciable impairment of vision existed; but, at this time, the eye was not examined by the ophthalmoscope.

*Remarks.*—In this case there are several interesting points to consider—viz., the development of paralysis of the external rectus, of strabismus, and of diplopia in the wards of an hospital in the case of a child who had some faintly marked symptoms of lead-poisoning, with a blue line on the gums, and alternations of constipation and diarrhœa. The lesion of the optic nerve caused but little disorder of sight, and might be considered as an optic neuritis complicating the paralysis of the sixth pair. Finally, we must bear in mind the disappearance of the strabismus and the diplopia, and the fundus oculi remaining in the same morbid state. All these phenomena seem to indicate the existence of, and cerebral affection due to, lead, which determined the cephalalgia, the optic neuritis, and paralysis of the sixth nerve on the right side with diplopia and strabismus. If the diplopia had been a consequence of neuritis, and had been produced as a disorder of ac-

\* *Traité d'Ophthalmoscopie, appliquée du Diagnostic de Maladies du Système Nerveux.* Paris, 1865, 8vo.

\* The original paper contains illustrations of the appearances seen with the ophthalmoscope.

commodation, it would have remained as long as the lesion of the fundus oculi; but as it disappeared with the cephalalgia, it is evident to me that it was the result of a temporary cerebral disturbance.

*Case 2.—Paralysis of the external motor nerve of the eye in consequence of chronic meningitis and optic neuritis, associated with granular retinitis—ophthalmoscopy—death—autopsy.*—Blanche Regnier, ætat. 8½ years, was admitted on Dec. 18, 1865, into St. Catherine's Ward at the Hospital for Sick Children, for a cerebro-spinal affection of two months' duration. At this time, either from the influence of fear, or in consequence of a fall on her head, the child had slight involuntary movements on the right side. These movements were similar to those of chorea, and they were accompanied with slight tremblings, and with weakness on the right side of the body. Sometimes, in consequence of these movements, the child fell, her eyes showing a slight convergent strabismus better marked on the right side, with a little corresponding dilatation of the pupil, and also some diplopia. The child, till then intelligent, appeared to become rather foolish; she no longer chattered, and she repeated the last words of the person who spoke to her; she walked with difficulty, and was somewhat bent; there was no impairment of the sense of touch; there was obstinate constipation with frequently recurring vomiting; the child had not at any time fever, and had not lost her appetite. In this state she was admitted into the hospital, and it was then found that if there was no fever, the pulse at least showed great irregularity, but no intermission.

*Ophthalmoscopy.*—At the fundus of the right eye there was the following change:—The papilla had completely disappeared, and was masked by a pearly grey infiltration, slightly blue, spreading rather extensively over the fundus of the eye. The veins were lost in this infiltration, and were as though interrupted in certain places. There were other vessels on the external side sufficiently large and flexuous to be easily distinguishable over a considerable extent, and which lost themselves in this amorphous product. Here and there small dilated veins resembling minute spots of hæmorrhages were seen; the arteries were not visible; the lesions in the left eye were very similar.

January 26th, 1866: Since yesterday the child can scarcely command herself, if she is seated on a chair she continually falls to the right side, and this morning she is in a state of marked somnolency, having no clear idea of things surrounding her, with loss of appetite, but without vomiting or constipation. With a pronounced yellowish pallor of countenance; pulse 80, rather unequal without intermission.

Feb. 8th: The child is very weak and in a state of partial insensibility. She oftens cries out; laughs without reason; starts when touched; eats very little; and passes fæces and urine involuntarily in her bed. Skin moderately warm. Pulse rather irregular, 80.

15th: The child remains in a state of semi-insensibility and weakness, which prevents her leaving her bed. She cries out every moment; laughs or cries without reason; starts when spoken to or touched. She eats little, and has involuntary evacuations. Her sight remains good to all appearance, the bottom of the eye shows the same lesions as formerly. There is no paralysis, but a little rigidity of the lower limbs.

21st: For three days past she has been much worse, the child's four extremities are in a state of complete tonic spasm; she lies on one side, her legs drawn up towards her body, and her wrists under her chin. There is no paralysis or insensibility; her muscles tremble and start every instant; she takes no notice of anything; and has cried without ceasing for two days. Pulse very small, frequent, and irregular, but not intermitting; and there is continual incontinence of urine and fæces. Died in course of the day.

*Autopsy.*—The brain was large, resistant, and compressed against the cranial walls. There was nothing peculiar in the arachnoid. The pia mater over the cerebral

hemispheres was throughout its whole extent considerably injected. It was of a red livid colour, and the veins of the membrane were full of liquid blood; here and there along the vessels there was a serous infiltration, whitish, and opaline, but without the appearance of well-marked pus. It did not contain any granular tubercle, and it adhered firmly to the grey substance, from which it was however detached without tearing the latter.

The sinuses were full of liquid blood, and there were no clots in any part. The brain-substance was firm and injected in the cortical portion, which was rough after detaching from it the pia mater. There was no softening of any part, no foreign body, no tubercle. The lateral ventricles were healthy, and contained no fluid. The optic thalami and corpora striata were healthy, and at the base of the brain, the membranes, the crura cerebri, the pons varolii, and the cerebellum, presented no change of structure. The optic nerves only showed some change in front of the commissure (canaliculis) and there was in the centre around them a yellowish substance, the structure of which was afterwards determined.

The eyes were found in the same state as during life, and on examining the fundus oculi with a lens, the papilla was found almost invisible, and covered by an extensive serous infiltration, near to it was discovered a yellowish projection formed by hypertrophy of the yellow spot, of the size of a grain of corn. The vessels were not very apparent in the centre, and traces of them only were found in the periphery. The structure of these parts was afterwards determined. The lungs presented but very slight lobular congestion, and there was only one small miliary tubercle, calcified, and as large as a grain of hempseed.

*Microscopical Examination.* (Note added by M. Comil). The small ovoid, yellow, and projecting spot, which was seen upon each retina, showed under the microscope the following characters: On spreading it on a glass slide, and examining it with a power of 200 diameters, a number of granular bodies were seen scattered about, composed of fatty granules, united in a common envelope, ovoid or spherical in form; other fatty granules without any investing membrane were also seen, contrary to our expectation (for we did not discover with the lens any vessels in the yellow part), there was a web of capillaries full of blood, fine, and forming a close network, as in the normal state. These capillaries, full of blood-globules, were small, not dilated, measuring from 0.006 to 1.008 m., and their meshes were very small, as is always the case in the retina. There were besides, on microscopical examination, yellow slightly-coloured particles, the result of extravasation of blood in this part of the retina, and the consequent separation of blood pigment. Such were the only lesions observed in the yellow portion of the retina, for this membrane retained over all the affected part its normal structure. The rods of Jacob's layer were granular and changed in form (post-mortem appearance). The layer of cells and nuclear particles and the fibres had undergone no noteworthy modification, but had preserved their structure and normal arrangement.

(To be continued).

**MEDICAL CHARITIES.**—At a meeting of the friends of the Hospital for Paralyzed and Epileptic Patients last week, when the Bishop of Oxford presided, it was announced that £600 was required to complete the undertaking, unencumbered by debt, whereupon Mrs. La Roche at once offered £100, provided fifty other contributors would give £10 each before the end of October next. The subscriptions towards the erection of a new infirmary for North Staffordshire have already reached nearly £15,000.

**POISONING WITH CROTON OIL.**—At the Liverpool police court, on Saturday, James McJaggart, mate of the ship *Manchester*, was charged with poisoning a seaman of the same vessel. McJaggart poured half a bottle of croton oil into a glass with some castor oil, and gave it to the man to drink. He became very weak from the effects of the oil, and died the next day.

## PROGRESS OF THE CHOLERA.

## LATEST INTELLIGENCE.

LONDON.—The disease has made rapid progress during the past week, and appeared in several new localities. On the morning of our last issue the report of the Registrar-General for the week ending Saturday, July 21st, appeared in the *Times*. It announced no less than 346 deaths from the epidemic, of which 308 occurred in the eastern districts of the metropolis. In Bow there were 39; in Poplar 52; in Limehouse 43; in Bethnal-green 30; in Mile-end 33. There had been 11 deaths in western districts, 20 in the southern, 6 in the northern, and 1 in the central. To this statement we may now add that at most of the large London hospitals cases continue to come, and at the London Hospital the epidemic is more alarming than even in 1849. On Thursday last there were 63 deaths in this hospital, 13 cases had recovered, and 74 remained under treatment. This makes up 150 cases—a number which has risen to above 200. Out of 124 cases admitted during the week, 67 had died on Saturday last, but many, although alive, were really dying. Between 20 and 30 cases have been distributed amongst Guy's, St. Bartholomew's, Charing-cross, the Middlesex, and other hospitals. In his report Dr. Letheby stated that in the city proper there had been no deaths nor any excess of diarrhœa. Since his report was dated this scarcely holds good.

We may state that at the City Dispensary during the week ending the 21st, relief had been given to 90 cases of diarrhœa without waiting for letters of recommendation, and that during last week (ending Saturday 28th), the number of urgent cases thus relieved had risen to 150. These cases were, of course, in addition to those who had letters for admission. At the *Dreadnought* hospital ship in the Thames several admissions, two deaths.

LIVERPOOL.—The medical men report the recent cases to be more serious than the earlier ones. In the last two days of last week 11 new cases were taken to the workhouse, 10 of which arose in the town. One case was taken from the Bank hall warehouses. One or two cases are said to have occurred among the higher classes; a member of a firm of cotton-brokers died in two hours. About 200 cases of diarrhœa at the dispensary on Thursday.

WINSFORD, CHESHIRE.—18 deaths last week as against 15 the week before. It is proposed to adopt at once the Local Government Act.

SOUTHAMPTON.—From July 7th to 24th there had been 120 cases, of which 66 were fatal. Extra medical men have been engaged by the Local Board of Health to attend on the poor. In the cholera hospital an excellent regulation is established—viz., the practitioner who sends the case is permitted to treat it himself or not at his option.

OTHER PORTS.—At South Shields several cases have occurred, 3 fatal. At Sunderland no fresh death up to Friday had come to our knowledge.

SOUTH WALES.—At Llanelly no improvement, but the disease has not spread to other towns.

SCOTLAND.—Preparations have been made at Leith, where it is feared vessels may bring it. Indeed two steamers have been properly prevented coming in on account of suspicious cases. No death reported, however, up to the 20th. At Perth an insane inmate of the Penitentiary has died of Asiatic cholera. At Dundee several deaths from diarrhœa and dysentery of a suspicious type.

THE CONTINENT.—Reliable information reaches us to the effect that the epidemic still increases. At Amiens the deaths are again 30 or 35 per day. At Dunquirre and Rouen there are many cases. In Paris, the authorities conceal, as far as possible, the state of affairs. A correspondent of a contemporary declares there were 1500 deaths last week from cholera. He may have meant 1500 cases. Another correspondent speaks of 100 cases a day or more treated in hospitals and private practice; at Marseilles 16 to 20 deaths per diem; at Berlin 700 cases reported up to the 21st; at Stettin no improvement. The statement that the disease had appeared at Boulogne-sur-Mer has been officially contradicted.

THE CHOLERA AND THE VESTRIES.—The violent epidemic which has broken out in the East-end of London has been the one topic of the week. On Wednesday morning the returns of the Registrar-General appeared, and since this startling document all the papers have devoted leading articles to the subject. It was from this official source that London first learned that the deaths from cholera have advanced during the last five weeks from 6 to 14, 32, 346, and 904, while the deaths from diarrhœa have been 67, 102, 150, 221, and 349. It was well that the Registrar-General pointed out that this excessive mortality was entirely confined to a very circumscribed area of the metropolis, and that this area was supplied with water from the river Lea, which is in "dangerous proximity to sewers, cuts, and canals." Knowing as we do that mere filtration is but a slight protection against many organic impurities, this is a subject deserving the utmost attention. An official inquiry into the facts of this epidemic is about to be made under the direction of Mr. Simon of the Privy Council, and there is little doubt that it will be ably conducted and prove of great value. But pending this inquiry means ought to be formed to remove the filth that in too many cases is spreading the disease. The tanks and butts in which the water is accumulated ought to be removed, and a constant supply granted. Nuisance inspectors and medical officers ought to be appointed in large numbers, and the vestries ought immediately to enforce the strictest sanitary regulations. Has not the Registrar-General pronounced that the authorities seem "paralyzed." Let them be up and doing. The warnings that the profession has for the last few years been uttering are now being realized. We learn with satisfaction that in Marylebone eight new medical inspectors have been appointed, dispensaries have been opened in every district, and the gully-holes and sewers are flushed daily with carbolic acid. On the other hand, a correspondence has been published, in which the vestry clerk in Chelsea writes to the Poor-law Board to inquire if the aid of the police may be invoked to carry out the recent orders in Council. He is very properly instructed from the Council Office, Whitehall, that "the assistance of the magistrates should be sought for in the removal of any impediment to the execution of the regulations issued by their Lordships under the provisions of the Diseases Prevention Act." At St. Pancras vestry we learn that one enlightened local representative "complained that the cholera committee appeared inclined to spend the ratepayers money like water; thought there was some jobbery somewhere, and should oppose the committee having the power sought for." This careful vestryman was defeated in his opposition by 26 against 17. If such senseless opposition be encountered in such a crisis as the

present, we need no longer wonder at the apathy which characterizes our local authorities in ordinary times.

**THE HEALTH OF LIVERPOOL.**—We recently drew attention to the peculiarly unhealthy state of this port, pre-  
saging for it a large mortality from the threatened epidemic which has since so severely visited it. The quarterly report of the Registrar-General has just appeared, and its figures demonstrate that Liverpool is a national danger. The rate of mortality for the first six months of the year was no less than 41.6 per 1000. A few years ago the mortality of Liverpool did not exceed 26. Whence, then, this fearful increase of preventible disease and death? The mortality from zymotic diseases in our chief port is growing constantly. 3081 deaths, or an increase of 1292 on the corrected average, is the figure printed in the official record. The last half year has registered as many deaths at Liverpool as the whole year 1860.

**THE BROAD-STREET PUMP.**—The local authorities have replaced the handle of this pump which had been removed during the last epidemic of cholera, in consequence of the late Dr. Snow tracing to the use of its water the fearful outbreak in the neighbourhood of Golden-square. The mad act of the board has produced a joint letter in the *Times* from Professors Miller and Frankland, stating that only last year analysis showed this water to be little else than sewage filtered through the soil. The good water to be had since the Drinking Fountains Association commenced its valuable work should enable us at once to close all the pumps in the metropolis, much more this to which so many deaths have been distinctly traced.

**THE CHOLERA WARDS OF THE LONDON HOSPITAL.**—At this institution various methods of treatment have been tried by the indefatigable staff, but the large number of cases render a full record utterly impossible. Those who have not witnessed an epidemic of this kind can have no idea of the extra work thrown upon the staff. Forty or fifty post-mortem examinations have been made and some records of them kept. Last week there were 158 fresh admissions, out of which 73 were fatal. The Secretary has been obliged to appeal for aid, and the *Times* has lent its powerful columns to advocate the cause of this over-worked charity. We would ask how it is, that a much larger amount of medical assistance is not available? Would not old London hospital students, looking forward to a place on the staff, accept a temporary post. A few deputy assistant-physicians might gain invaluable experience by studying such an epidemic.

**CHOLERA IN PARIS.**—The *Courrier Médicale* declares that the health of Paris is improving. The *Gazette Hebdomadaire de Médecine* gives the following as the nearest approach to the number of deaths from cholera at which they could arrive in face of the indisposition of the authorities to permit inquiry:—

|         |   |   |   |   |     |
|---------|---|---|---|---|-----|
| July 19 | . | . | . | . | 116 |
| 20      | . | . | . | . | 142 |
| 21      | . | . | . | . | 106 |
| 22      | . | . | . | . | 89  |
| 23      | . | . | . | . | 92  |
| 24      | . | . | . | . | 94  |
| 25      | . | . | . | . | 90  |
| 26      | . | . | . | . | 86  |

**CHOLERA CASES IN SIR P. DUN'S HOSPITAL.**—A special meeting of the governors of this hospital was held on the 3rd inst., to receive a deputation from the guardians

of the South Dublin Union respecting the admission of cases of cholera. The following resolution was unanimously adopted:—"That cholera patients be received into Sir Patrick Dun's Hospital on the order of the guardians of the South Dublin Union, so far as the accommodation provided in the cholera wards shall admit of their reception; and provided such patients be brought from the districts of St. Mark's parish and Ringsend, or from a distance not greater than half a mile from the hospital." In opening wards for the reception of cholera cases, the governors of the hospital resolved to confine their operations to the poor of their own locality as having a special claim on the services of the institution. Mrs. Meyler, the last member of the family attacked at City-quay, died in this hospital on Sunday morning last.

**CIRCULAR FROM THE POOR-LAW BOARD.**

Poor-law Board, Whitehall, 27th July, 1866.

SIR,—In consequence of the outbreak of cholera, the Poor-law Board have already transmitted to you, for the information of the board of guardians, a copy of the regulations recently issued by the Lords of the Privy Council under the Diseases Prevention Act, 1855, and the amending act 23rd and 24th Vict., c. 77. By the provisions of the 23rd and 24th Vict., c. 77, sec. 11, the vestries and district boards under the 18th and 19th Vict., c. 20, are the authorities for carrying into execution those regulations. But these statutes do not remove from the boards of guardians the responsibility which the law has imposed upon them in regard to the relief of the destitute poor. The epidemic will necessarily create much additional suffering, and may probably cause a great increase of destitution among the poorer classes of the metropolis.

The Poor-law Board are satisfied that the guardians will not relax their exertions because the vestries and district boards are made responsible for the performance of the duties created by these regulations; and that the guardians and their officers will coöperate whenever practicable with those authorities.

The guardians are fully justified in calling to their aid such medical and other assistance as in their judgment the emergency may require. They can also provide those purifying and disinfecting agents which their medical officers recommend as requisite in the dwellings of the sick poor, and such additional sustenance or clothing as the peculiar circumstances may render necessary. In all these respects the powers and obligations of the guardians remain in full force.

It is inexpedient that the accommodation to be provided for cholera patients should be in the workhouse or on the workhouse premises. As far as practicable, therefore, the admission of cholera patients into the workhouse should be prevented.

The guardians should procure for themselves and their officers the fullest and earliest information as to the arrangements made by the vestry or district board, so that due notice may be given to every person who may require aid from the guardians of the arrangements applicable to the case, and how and where the requisite attention can be obtained.

The Poor-law Board will pay immediate attention to any communication which the guardians may address to them, and afford them any assistance in their power in the discharge of the duties and responsibilities imposed upon them.—I am, Sir, your obedient servant,

GATHORNE HARDY, President.

To the Clerk of the Board of Guardians.

A CASE was lately shown before the Société d'Anthropologie of Paris which would seem to lend great support to M. Broca's and Dr. Hughlings Jackson's views upon the subject of aphasia. A man was struck with hemiplegia of the left side without any affection of speech. Two years afterwards he had a fit of apoplexy, and this time his right side was paralysed, and he lost the power of expression. He died, and on examination there was found—1st, in the third cerebral convolution of the right side a hæmorrhagic cavity in process of cicatrization; 2nd, in the corresponding convolution of the left side a recent hæmorrhagic clot; this last evidently having determined the right hemiplegia with aphasia.

## NEW DISCOVERIES IN DIALYSIS.

AMONG the papers read at the closing meeting of the Royal Society's session, there was one by the Master of the Mint, which is likely to engage the attention of chemists and metallurgists, for it carries on, and with striking results, the researches arising out of Mr. Graham's important discovery of dialysis. Treating of the absorption and dialytic separation of gases by colloid septa, the first part of the paper gives the results obtained by a septum of caoutchouc, and the second part those of different metallic septa at a red heat. It has long been known that palladium and some other metals, when heated, absorb gases. Mr. Graham now finds that palladium will take up several hundred times its bulk of hydrogen, and that iron at a low red heat absorbs a considerable quantity of carbonic oxide; and that, contrary to long-standing belief, this gas does not act on the surface of the metal only, but permeates its entire substance. This fact is particularly interesting to metallurgists. Having taken up the gas, the iron will retain it for any length of time, and in this condition is best adapted for conversion into steel, as by the permeation of the carbonic oxide the subsequent process of carbonization is largely facilitated. Hence arises the suggestion that the process of acieration would be best accomplished by changes of temperature; a low red heat to fill the iron with carbonic oxide, after which it may be put away, if required, to await the final process at a high temperature of conversion into steel. Concerning another form of iron Mr. Graham remarks that wrought iron, in the course of its preparation, "may be supposed to occlude six or eight times its volume of carbonic oxide gas, which is carried about ever after. How the qualities of iron," he asks, "are affected by the presence of such a substance, no way metallic in its characters, locked up in so strange a way, but capable of reappearing at any time with the elastic tension of a gas, is a subject which metallurgists may find worthy of investigation." It would not be easy to overrate the importance of the paper of which we have given here so brief a sketch, for it is remarkably suggestive and original throughout. When published in the "Philosophical Transactions," with all the details, it will secure the attention it deserves. If Mr. Graham had never written more than this paper, it would suffice to place him in the foremost rank of the chemists of Europe; and it may be that metallurgists will now be ready to claim him as one of themselves for what he says about iron and other metals.

## STEAM AS A DISINFECTANT.

IMPORTANT experiments have been carried on during the last few weeks under the supervision of Dr. A. N. Bell of Brooklyn, aided by Drs. Stiles, Conklin, J. Lee, and others. The experiments were made at Seguin's Point.

Dr. Bell contends that steam is a far better disinfectant than chlorine, the latter remedy rotting the clothes, while the former is thoroughly efficacious, and makes not the slightest difference in the clothes, beyond the great one of disinfecting them of all disease.

The apparatus used for the experiments was simply an ordinary steam boiler of three horse power, and a Woodward's force pump—the latter connected with a coil of pipe 360 feet in length, enclosed in another furnace, by which the steam from the boiler is superheated and makes dry steam. From this furnace a section of pipe is carried to a small chamber containing about 500 cubic feet, in which the disinfecting is to be done. The pipe was in the centre of the floor, from which the steam is concentrated. On the wall was a self-registering thermometer; on the top of the partition of this room was another thermometer, and at the bottom still another. These were placed there to mark the different degrees of temperature during the experiments.

The experiments commenced by a five minutes' test, during which time some oysters, clams, fish, and three eggs, through eight thicknesses of blanket were cooked. By this it was understood to show that all animal matter being subjected to the action of super-heated steam will at once be destroyed. At the commencement of the test the lower thermometer marked 90 degrees Fahrenheit, and the upper

one 83 degrees. During the five minutes occupied in the experiment the gauges of heat stood as follows:—

| Minutes. | Lower Ther. Degrees. | Upper Ther. Degrees. |
|----------|----------------------|----------------------|
| 1 ... .. | 105                  | 120                  |
| 2 ... .. | 155                  | 178                  |
| 3 ... .. | 185                  | 220                  |
| 4 ... .. | 202                  | 202                  |
| 5 ... .. | 200                  | 198                  |

A second test was then made, which lasted ten minutes—oysters, eggs, &c., being put in as before, as well as a coat and a pair of white linen pantaloons. Before the door was shut the indicator marked 162 degrees (the lower) and 140 degrees (the upper). The annexed table will show the various degrees of heat obtained:—

| Minutes.  | Lower Ther. Degrees. | Upper Ther. Degrees. |
|-----------|----------------------|----------------------|
| 1 ... ..  | 167                  | 165                  |
| 2 ... ..  | 180                  | 190                  |
| 3 ... ..  | 185                  | 196                  |
| 4 ... ..  | 192                  | 202                  |
| 5 ... ..  | 195                  | 210                  |
| 6 ... ..  | 198                  | 214                  |
| 7 ... ..  | 202                  | 216                  |
| 8 ... ..  | 202                  | 216                  |
| 9 ... ..  | 205                  | 220                  |
| 10 ... .. | 208                  | 225                  |

The self-registering thermometer indicated 260 degrees. Dr. Bell accounted for the variation of the lower and upper thermometers by the fact of the lower one being connected with the chamber by an iron tube. Iron being a conductor of heat prevented it marking the graduations of heat correctly. The clothing placed in the room was perfectly dry and the linen pants, now considered perfectly disinfected from all disease, were as dry as a bone, and the starch and folds made by ironing were not even taken out of them. This, Dr. Bell claims, is done by his steam being superheated, which is the secret of his success as a disinfectant. To thoroughly cleanse and purify the clothes of emigrants and passengers will take two hours; at the end of which time it will be considered safe to allow them to go anywhere they please.

A retort can be attached to the steam pipe, capable of injecting any volatile substance or disinfecting agent into the chamber, such as chlorine, carbonic acid, fumes of coal tar, &c. If used, these chemicals will be heated to the utmost intensity, thus giving them greater power.

It is stated that a ship can be disinfected in the same way. The boilers of a tug will be used, and a portable super-heat apparatus be erected on board. In one day a ship, by this plan of disinfecting, can be thoroughly purified, and she will be enabled to come to the city in safety. If this is the case it will be the saving of many thousand dollars to our merchants and shipowners.—*Philadelphia Medical and Surgical Reporter.*

## Reviews.

## A MANUAL OF MEDICAL JURISPRUDENCE.

By ALFRED SWAINE TAYLOR, M.D., F.R.S., Professor of Medical Jurisprudence and Chemistry in Guy's Hospital. Eighth Edition. Pp. 707. London: Churchill and Sons. 1886.

A MANUAL so well known as that of Dr. Alfred Taylor, and which has reached its eighth edition, carries with it its own recommendation. It may, however, be necessary to mention for the benefit of two very distinct classes of readers that there are now two works on the same subject by Dr. Taylor, one entitled the "Principles and Practice of Medical Jurisprudence," and the other the Manual now before us. The first is a complete Encyclopædia of every thing relating to medical jurisprudence, and is amply illustrated by cases described in detail; the second contains the same matter in an abridged form, and the details of cases are omitted. The larger volume will therefore be consulted by the learned as a book of reference, and the smaller and more condensed work will serve, as it has

hitherto done, as a hand-book for students and practitioners in getting up the subject of medical jurisprudence or in refreshing their memory upon particular topics. For the information and guidance of medical men, two chapters on evidence and the duties and responsibilities of medical witnesses have been placed at the commencement of the volume, and we need scarcely observe that they contain a great amount of useful and instructive matter; and among other minor changes which have been made in the present edition, there are numerous engravings introduced representing the crystalline forms of poisons and the apparatus used for their detection. We need to add no further remarks beyond again cordially recommending this Manual to the professions of law and medicine.

**BRIEF NOTES ON THE LAST EPIDEMIC OF CHOLERA IN TURKEY:** with Observations as to Prevention and Treatment. A Report submitted to the Committee of the Seamen's Hospital Society, with Addenda. By HARRY LEACH, Resident Medical Officer, Hospital Ship "Dreadnought," and late Medical Inspector to the Kustendjie and other Turkish Railways. London. 1866. Churchill and Sons.

THIS pamphlet is one of a croud of cholera literature that the last epidemic has brought forth, and may claim perhaps additional attention as a short record of experiences culled from a city that is always the nucleus of the disease in Europe. Constantinople has constantly been visited with cholera in all its unmitigable severity, unchecked by any sanitary efforts, and consequently, raging most furiously, and working its will without let or hindrance; and so these pages are valuable, in that they tell us how completely the convictions of our Privy Council Medical Officers as to the contagiousness of the disease are borne out by the evidence of those in Turkey, who have seen more cases of cholera than any other clique of medical men in Europe. The pamphlet says little as to remedial agents, and we shall probably hear from the author at some future time the definite results of hypodermial injections which appear to be the only class of remedies spoken of with any confidence in his paper. An official connexion with the *Dreadnought* Hospital Ship will doubtless afford him an opportunity of giving this plan a fair trial.

**NOTE-BOOK OF MATERIA MEDICA, PHARMACOLOGY, AND THERAPEUTICS.** By R. E. SCORESBY-JACKSON, M.D., F.R.S.E. Edinburgh: Maclachlan and Stewart.

UNDER the deprecatory title of a "Note-book," Dr. Scoresby-Jackson has presented the profession with one of the most full and comprehensive works upon the materia medica, and upon the art of prescribing remedies which has for long appeared in an English dress; and when we say full and comprehensive, we, of course, desire to be understood as speaking of the amount of essentials contained in this little work of 632 pages, and not as to fulness of detail on every point—a matter of necessity confined to similar works of a larger size and more pretentious claims, yet this little work is a perfect model of condensation and accuracy. There is, perhaps, no known remedy, officinal or otherwise, which does not find a place in its pages, and its very index is made to convey that most important information—the dose of the drug referred to—so that in turning it up, a practitioner will often get

**CHOLERA CASES.** For the mere student this little meeting of the table. Starting with the naturally—the 3rd inst., to re

for a teacher of materia medica—rather overstrained idea that "the ultimate object of medical education is to teach *how to write a prescription*," the author proceeds to explain the principles which ought to guide us in the selection and collection of medicines, the nature and effect of those circumstances which influence the therapeutic value, more especially of vegetable remedies, including under this head, of course, an account of the nature of the various active principles of vegetable medicines, he then treats of pharmaceutical operations, and of weights and measures. Passing on to the consideration of officinal formulæ, and giving under this head all necessary information as to the composition, temperatures to be employed, &c., in regard to the formulæ for waters, tinctures, liniments, pills, powders, ointments, &c., contained in the British Pharmacopœia, as well as exhibiting at a glance the composition of each of them, and finishing off this introductory part by a very full consideration of "majutral formulæ"—that is, of the act of making *extempore* prescriptions—a part of the teaching of the uses of the materia medica too often wholly omitted, both from works and lectures, upon the subject. Under this latter head Dr. Scoresby-Jackson considers—1st, the properties and effects of remedies; 2nd, their *modus operandi* and classification; 3rd, the locality of their action; 4th, the channel of their introduction; 5th, the circumstances which modify their action; and 6th, under the head of the prescription, he shows how the information already acquired may be usefully embodied in the construction of a prescription suited to the requirements of each case, describing minutely the object sought to be obtained in the combination of various ingredients. In this, however, Dr. Scoresby-Jackson has perhaps adhered too closely to his predecessors, and while pointing out that the tendency of modern prescriptions has possibly erred too much on the side of simplicity, he has omitted to show in how far and in what manner complexity may be useful. It is one thing to prescribe a heterogeneous mixture of drugs possessed of diverse counteracting powers, and quite another to prescribe a combination of various drugs possessed of similar powers, each efficacious, mayhap, under divers circumstances. The tendency of the best practitioner of the present age is towards the latter mode of prescription; that of our forefathers was towards the former. It would have been well to have pointed out the distinction and the difference.

The remaining part of this work is occupied by a condensed yet clear and concise account of the natural history, composition, preparations, actions, and uses of the various articles comprising the materia medica; not merely those which are officinal or comprised in the British Pharmacopœia, but also including many others which, though excluded from that work, are yet deservedly prized by many practitioners of medicine. It would occupy too much space to enter upon a detailed consideration of this part of the work; it is sufficient to say that it is executed with the same diligent care evinced in the introductory part, and that in its construction the interests of both practitioners and students have been carefully consulted. This little work is dedicated by permission to Professor Christison, and the highest praise that can be bestowed upon it is to say that it is not only not unworthy to be so dedicated, but also not unworthy of the high reputation which Professor Christison has won for the Edinburgh Medical School in the matter of Materia Medica, Pharmacology, and Therapeutics.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 8, 1866.

## VISITATION OF EXAMINATIONS.

WE are enabled to publish below an important letter from Mr. RUMSEY of Cheltenham, one of the representatives on the General Medical Council appointed by HER MAJESTY, in respect to the proposed Visitation of Examinations by the Council, in which he was called upon to take part. We have the more satisfaction in making public this protest of Mr. RUMSEY's, because his very logical reasons for dissenting from the determination of the Council have been kept back by the Council, lest the profession might exercise their right to judge for themselves in this matter, and perhaps arrive at an unfavourable conclusion:—

MY DEAR DR. HAWKINS,—Circumstances over which I have no control prevent my attending the meeting of the Branch Council to-morrow; and as it appears from your notice of "Agenda" that the main business of that meeting will be to make arrangements for the visitations of examinations, I beg you will do me the favour to communicate to the President and the Members of the Branch Council my reasons for requesting them to excuse my continued inaction in this matter.

I have uniformly objected to the measure, both in principle and in detail; and the results of the recent visitation have in no degree removed my objections.

Although a majority of the General Council has so interpreted the last sentence of section xviii. of the Medical Act, as to found on it a resolution (April 6, 1865) that the Branch Councils, or such of their members as may be deputed by them, shall visit the examinations, preliminary and professional, conducted by the qualifying bodies, and report thereon to the General Council, there still exists a minority who do not so understand that provision of the Act, which, in their opinion, is merely permissive, and not intended to supersede any more correct or efficient method of attaining the object in view.

I believe that had it been left to each Branch Council to decide for itself whether it should depute its members to visit the examinations of the licensing bodies within its jurisdiction, the English Branch would not have agreed to undertake such visitation, and the Irish Branch would have peremptorily negatived the proposal. I believe that, in fact, we owe the adoption of this very questionable measure, by the General Council, to the unanimity and energy of our Scottish colleagues.

The manifest diversity of opinion on this point among the three nationalities in the Council, may, I think, justify any individual member in declining to accept his share of responsibility in this proceeding.

But, if I am mistaken, and if it were to be decided by legal authority, not only that the minority are in error, but further that they are bound to aid the majority in the performance of these visitations, undertaken voluntarily, and on a disputed interpretation of the Act, I for one should feel it my duty—though with much regret—to resign my seat in the Council.

I will now state, as briefly as I can, my principal objections to the present system of visitations.

A. If it be granted that the examinations of candidates

by any of the qualifying bodies, represented in the Medical Council, are so defective in their nature and so fallacious in their results, as to require the employment of some external agency to inspect them and report to a controlling and reforming authority (which I by no means assert), it would, I think, be obvious to every intelligent and impartial observer, that the representative members of Council ought not themselves to constitute that agency.

Even were the theoretical objection set aside, it does not yet appear how any members of Council can do the work at all satisfactorily or effectively: (1) because, with their utmost diligence and their largest possible expenditure of time and labour, they can be present at only a very small proportion of the many examinations held annually by the medical licensing bodies; (2) because the same gentlemen, however able and accomplished, can hardly be expected to superintend with equal thoroughness and efficiency those examinations in all branches of knowledge—general, scientific, and professional—which, at various stages of his education, each medical student has to pass through; and (3) because the representatives of the licensing bodies, though themselves free from corporate bias or interested motive, are not likely to satisfy the requirements of the profession, the public, and the Government, by undertaking a duty which makes them, as a body, judges in their own case.

Here, however, I beg not to be understood as supporting an objection which has been lately (and forcibly) made to "reciprocal visitation by the representatives of rival bodies," as though such attendances must necessarily degenerate into a mere exchange of empty courtesies, if not of invidious remarks. For this objection seems to assume what is not the fact—viz., that the licensing bodies are really "rivals," similarly constituted for similar purposes, conferring similar qualifications, and alike open to the same kind of criticism. It also implies a suspicion—not to be entertained for a moment—of the honour and justice of the visitors.

B. Assuming, for the sake of argument, that the regular attendance of appointed visitors or assessors is a sound and true method of securing the thorough efficiency and trustworthiness of examinations as tests for legal qualification, it follows that such visitors ought to be constantly present, each devoting his attention to those subjects with which he is most conversant, and on which his authority is unquestionable. Such a system, as I have said, cannot be carried into effect by members of the Council. Yet there is no reason why the Council should not be empowered to appoint and to regulate the duties of visitors not belonging to their body.

C. But a far better and surer means of testing the practical results of courses of medical study and examinations, than visitation or inspection of any kind, would be to establish in each division of the kingdom—at least in England—a Board of Examiners for all public medical appointments.

Every candidate for the medical or surgical charge of hospitals, asylums, prisons, workhouses, and districts, should be required to possess not only one or more of the existing legal qualifications, but also the testamur of a National Examining Board, which would thus confer upon the masses of the civil population the same security as the Army and Navy Medical Boards now confer on the populations of their respective services, and which, without requiring any additional qualification for mere private practice, would inevitably tend to raise the standards of qualification required by the several corporate bodies.

On a proper occasion I shall be prepared to show how the proposed measure might be carried out in detail.

I may at once mention that the existence of such a Board would supply a serious public deficiency, which none of the Universities have hitherto attempted to supply—I refer to the want of some reliable test or certificate of fitness for

the higher offices of state medicine—i.e., for important sanitary and medico-legal appointments, a subject on which I have published some remarks.

The establishment of a NATIONAL EXAMINING BOARD FOR THE CIVIL MEDICAL SERVICE would, of course, require an increase of public expenditure; and I think it would be impossible to apply a portion of the funds at the disposal of the Medical Council to a more worthy or important object, alike beneficial to the community and honourable to the profession.

Some such provision for higher standards of medical education, and higher degrees of qualification, ought to be embodied in the Medical Act Amendment Bill.—I am, dear Dr. Hawkins, yours very truly,

H. W. RUMSEY.

Cheltenham, June 14, 1866.

The perusal of Mr. RUMSEY'S letter will be none the less instructive to our readers, because they may dissent, as we do, from a part of it. There are many points in it worthy of notice, which must be treated separately. In the first place, Mr. RUMSEY suggests that the determination to carry out the proposed visitation did not originate with the English Branch of the Council, that it met with the strongest opposition on the part of the Irish members, and that it was passed by the active support of the Scotch Representatives. Here, alone, is a paradox worthy of solution, in the fact, which must be admitted, that the Scotch Licensing Corporations were the bodies who, through their representatives, might have been expected to oppose the visitation of their examinations. If the denunciations of the examinations of the Scotch Colleges, which we have read in the proceedings of the Council and elsewhere mean anything, they ought to signify that the visitation clause of the Medical Act was enacted specially for their behoof. We are not, at least, saying too much when we allege that the Scotch Colleges are not more innocent of diploma traffic than their English and Irish neighbours, and therefore their clamorous demand for inquiry, visitation, and investigation is almost incomprehensible. Altogether incomprehensible it would be if we believed in the efficacy of the visitation to detect faults, or when found expose them, but easily to be understood if we regard the visitation as an empty form. It may convey to the uninitiated an impression of purity to demand an inquiry which turns out to be only a solemn comedy, and we can therefore understand how the cue might have passed to support the proposition, and thus gain character for candour without fear of the real *exposé* being required.

We need not recapitulate Mr. RUMSEY'S reasons for believing that the visitation of examinations by the Council must prove futile, if not absolutely injurious. He thinks that councillors cannot effectually pronounce on examinations, because: 1. They can inspect then but very inefficiently. 2. They cannot be judges of all the subjects. 3. They are constituted judges in their own case. None of these arguments, strong as they are, appear to us as conclusive as that which Mr. RUMSEY repudiates—that the visitations “must necessarily degenerate into a mere exchange of empty courtesies, if

not of invidious remarks.” This point was well put by Sir DOMINIC CORRIGAN in one of his speeches, and it is of itself fatal to the existence of any confidence on the part of the public in the verdict of the visitors. It is a farcical expectation that a just conclusion of the character of the general run of examinations can be formed by every, the most conscientious, visitor, sitting by previous appointment to listen to questions and answers prepared with the knowledge of his advent. With the highest respect for the gentlemen of whom Courts of Examiners are constituted, we say that there are few who would not, even unconsciously, modify their examination. Which of us, if we knew that we were under official inspection, would not make an effort to furbish up our effete stock of questions, or infuse a just urbanity into our manner; and which of us would incur such a storm as would be called forth by an uncompromising verdict against the examination of any College. As Sir DOMINIC CORRIGAN expressed it, the examination would be necessarily “figged out” for inspection, and, as Mr. RUMSEY says, the Report would be only a “mere exchange of empty courtesies.”

If visitation is not the way to cure the evil, neither is Mr. RUMSEY'S panacea—the NATIONAL EXAMINING BOARD FOR THE CIVIL MEDICAL SERVICE—which to our mind appears a medicine more dangerous than the disease. The sense of the profession will dispose of the proposition better than we can.

The National Examining Board must qualify practitioners either on its own sole responsibility or, like the Army Competitive, in conjunction with the licensing bodies. If it is intended that it should act alone as sole Central Court of Examiners for all schools, then it involves all the difficulties of a single standard of education. Its standard must be either too high for the General Practitioner or too low for the University Graduate, for there is no mean in the requirements of medical men any more than in the necessities of the public. A carpenter with a whitlow on his finger does not want a highly qualified and highly paid medical man, while a Duchess in her confinement will not be content with a third-class practitioner. All the objections which have been urged to the enactment of a minimum standard of education apply to Mr. RUMSEY'S proposal, and no corresponding advantage can be claimed for it.

If, however, the Central Board is intended to act as supplementary to the examinations of licensing bodies, it is only a clumsy expedient to avoid the necessity for dealing with the deficiencies of these bodies themselves. If the standard of examination be fixed at the lowest, what is gained by a Central Board, which does not correct the underselling system—if a high position be taken why not deal with the erring licensing bodies themselves and compel them to advance in the scale. The Medical Council should bear distinctly in mind their proper function and should direct their efforts towards its attainment. They have simply to take care that no man undertakes to treat disease without being able to afford

sufficient evidence that he is qualified to do so. The Council have to fix the lower limit of medical qualification, not the upper, and in our opinion they will effect that purpose neither by Visitation of Examinations nor by the National Examining Board.

### THE CHOLERA IN LONDON.

It is now only too evident that the cholera has established itself again in the metropolis of the empire, but with the capricious and erratic predilection for certain localities which it has so often manifested, it has hitherto appeared chiefly in the eastern suburbs of London, and what is still more extraordinary, there is as yet no evidence of a direct kind that the present epidemic has been imported from abroad. The Seamen's Hospital Society applied some few months since for a hulk to be moored astern of the *Dreadnought*, off Greenwich, for the reception of cases which it was anticipated and feared might be brought into the Thames from foreign infected ports, and the *Belle Isle*, an old seventy-four, was appropriated to the purpose. On board the *Dreadnought* itself the greatest vigilance was exercised in examining every suspicious case, but up to a very recent period no cholera patients presented themselves, and even choleraic diarrhoea was by no means prevalent. At last, however, about a fortnight ago, a patient was brought to the ship suffering from unquestionable symptoms of malignant cholera, and was at once transferred to the *Belle Isle*, and died in a few hours. On the same occasion two women were brought to the ship from a barge coming from Boulogne, but as there was no accommodation for females on board the *Dreadnought*, they were transferred to Guy's Hospital. On this barge a man had died on the passage from Boulogne, and the two females were the wife and daughter of the deceased.

The curious and anomalous circumstances attending these cases were, that Boulogne, so far as we know, is not suffering, and has not suffered, from cholera, and therefore there is no evidence of infection from that port; and as for the other man who died on board the *Belle Isle*, he had been ashore for three weeks, and had come from Canada. Up to the time of our writing, cases of decided cholera have been daily admitted on board the *Belle Isle*, and a considerable proportion have died; but the same absence of proof of foreign infection has prevailed, all the cases having come either from the barges on the river, or from the lodging-houses of Poplar or Limehouse, or other places on the river side. Further investigation may perhaps show that some of the cases have been infected in foreign ports; but whatever may be the facts ultimately discovered, we are only stating the truth in asserting that at present no proof of such infection can be said to exist.

If, therefore, a system of quarantine had been adopted, so as to exclude the disease from being imported along the river Thames from foreign countries, it is but too obvious that any such precautions would have been use-

less. Preparations would have been made for meeting an enemy in the front, where he did not exist, while all the time he was in the rear and in the flank.

With regard to the question of treatment we are still compelled to speak with the utmost caution and reserve, but we think it our duty to discourage in the strongest terms the use of castor-oil as a specific in this disease. We think it the more necessary to do so, as the *Times*, with its usual imprudence in such matters, has very lately given nearly two columns of its space to a renewed recommendation of this more than doubtful kind of medication. Not only is such a recommendation calculated to inspire false hopes, but we are by no means sure that it will not lead to considerable mischief, and that in carrying out into practice a specious though untenable hypothesis, many lives may perhaps be sacrificed. If the *Times* had taken the trouble to inquire of the Royal College of Physicians of London what was the opinion of that learned body as to the castor-oil treatment of cholera, it would have received a pretty decisive answer in the shape of a report, published in our columns this day, presented to and adopted by that College, and drawn up by a committee, of which Dr. GEORGE JOHNSON, the advocate of the castor-oil treatment, is himself a member. This committee, although it does not in distinct terms condemn this treatment, is very far indeed from adopting or approving it, and in reference to the use of castor-oil it recommends the limitation of its use to those conditions of looseness of the bowels which result from "bad or obviously indigestible food," and even in such cases rhubarb is recommended as of equal efficacy.

We may state that the principles of treatment recommended by the committee of the College coincide with those usually adopted in practice, and that the plan of checking the early diarrhoea by astringents and moderate doses of opium is plainly enjoined and strongly recommended.

The last return of the Registrar-General gives the appalling result of 904 deaths from cholera in London in one week, and the return also specifies the district in which the greatest part of this mortality occurred. It extends all along the north side of the Thames, from the River Lea and the Isle of Dogs, to the Tower of London, and comprises the districts of Bethnal-green, Whitechapel, St. George-in-the-East, Stepney, Mile-end, Oldtown, and Poplar, including Bow.

The following extract from the weekly return will give some idea of the ravages of the disease in the eastern part of London:—

"The mortality is overwhelming in some of the districts. In Poplar alone 145, in Bow 188 people died last week, including Dr. Ansell, the meritorious health officer, and Mr. Ceeley, clerk to the Board of Works, whose name figures on the placards. The people are falling ill every hour; you see them of all ages, children and adults, lying about their beds like people under the influence of a deadly poison, some acutely suffering, nearly all conscious of their fate and of all that is going on around them. Here the doctor is drawn in by the husband to see the wife now attacked; there the husband lies in spasms; here is an old

woman seated dead, with eyes wide open; there lies a fine four-year old child, his curly head drooping in death, but his mother says the pulse is strong, and he takes what she gives him. An older brother just recovered is running about. Several wards of the London Hospital are full of patients, many of them very young children in all stages of the disease; some dying, some well again and playing. The medical men have no rest, and with the health officers are nobly doing their duty; brave men ready to lay down their lives for their patients. The people themselves are most patient; most willing to help each other, the women always in front, and none shrinking danger. There is no desertion of children, husbands, wives, fathers, or mothers from fear. In the midst of this scene the authorities have been, to some extent, paralyzed. The nuisance inspectors are not sufficiently numerous, neither are the medical officers. The administrative work has not been organized with sufficient promptitude, and is not carried out with sufficient energy."

#### THE WORKHOUSE INFIRMARY OF ST. MARY, ISLINGTON.

IN a report just presented to the Poor-law Board by Mr. H. B. FARNALL, one of the Poor-law Inspectors, we are told, p. 5, that "the wards of many of the infirmaries" (that of Islington being, among others, particularly alluded to) "were not originally constructed in such a manner as to secure either sufficient ventilation or light with the greatest facility, or so as to empty the wards of foul air with the greatest speed. In some of the wards there are no windows opposite to each other, and there I could not detect the air to be moving through them. The pauper nurses did not know how to obviate this defect, except by widely opening the doors and windows and creating draughts." All this is quite true. But the Poor-law Board knew it all before, at least in the case of the Islington establishment, for in a report written on the condition of that building, and sent to the Poor-law Board in the year 1854, it is stated, among many other matters, to some of which we shall presently refer, that "the ventilation of the sick wards is deficient in the extreme," and in order that there may be no mistake about the exact situation of the wards referred to, the writer, who was one of the medical officers at that period, goes on to say that "the wards were known as No. 1 and No. 2, and the lying-in ward; and from what I have observed," he continues, "the chief mode of ventilating the wards throughout the entire infirmary appears to be effected by opening the windows, which are placed directly over the beds of the patients, some of whom suffering from chest affections, such as pneumonia, bronchitis, pertussis, &c., and others suffering from rheumatism, have had their diseases most seriously aggravated in consequence." This is almost as bad as the carpet-beating nuisance which has lately been abolished in the workhouse of the Strand Union.

The same gentleman goes on to state that in ward No. 8 he has "known at the same time three cases of syphilis and one of itch, and he has frequently known cases of fever associated in the same ward with other inmates who might be considered healthy, but far from able-bodied. In the female receiving ward, which contains four beds," he continues, "I have known to be

intermixed two cases of insanity, one of puerperal fever, one case of severe burn, one nurse, and three other healthy persons, and I have known them so to pass the night. In addition to the over-crowded state of the infirmary, numbers of cases, contagious and non-contagious, have occurred from time to time, for which there was no room in the sick wards, and consequently they were necessarily left either in the tramp sheds, which are totally unfit for sick persons, or in other parts of the house not usually devoted to the sick; such cases, for instance, as typhus fever, itch, gonorrhœa, syphilis, puerperal fever, cholera, erysipelas," &c.

These matters were all known to the local guardians and reported to the Poor-law Board, and at the end of twelve years we find that the trustees of the parish are *thinking* of building a new workhouse.

Now, on turning to Mr. FARNALL'S report on the existing condition of the St. Mary Islington Workhouse, page 45, we find him stating that the present Medical Officer of the establishment enjoys the distinction of being "the only Workhouse Medical Officer in the metropolis who considers that the services of pauper nurses are equal to those of paid nurses; he is also the only Medical Officer (with the exception of one other) who considers 500 cubic feet sufficient for each sick pauper in a workhouse."

It is probable that the condition of the Islington Workhouse may be different now from what it was in 1854; but at the last-named period the sick paupers did not get even the 500 cubic feet of atmospheric air, which the beneficent liberality of the present medical incumbent would allow them.

Turning to the report published in 1854, we find the then Medical Officer describing one of the abodes of the sick, called the Regions; "so called," he says, "from its situation, which is partly underground, very dark, with one small window, no ventilation, and very damp, the woodwork crumbling from mildew. Yet this place," he says, "is devoted to the reception of the paupers, and in consequence of all the other wards being quite full, the paupers were and are kept there. The dimensions of this room are such," and here the exact measurements are given, "that as seven persons constantly sleep there, each person has 355 cubic feet." Comparing this statement with a note in the same report, we find that the convicts at the Pentonville prison are each allowed a space equivalent to 820 cubic feet, in which, moreover, the air is constantly renewed by appropriate ventilating machinery.

But not only did the elements of disease thus exist in perfection in the Islington Workhouse in 1854, but disease itself actually broke out. The number of cases of contagious fever is carefully recorded, and there was no negligence in registering each case with its treatment and the results. The Poor-law Board were made fully acquainted with all the particulars, and two of their Inspectors verified the statements as to the condition of the wards, and they themselves mea-

sured the cubic dimensions of air allowed to the patients; and we repeat our sentiment expressed last week that the Poor-law Board are convicted, in this instance at least, of a gross dereliction of the duty imposed upon them by the State. Whatever may have been their ignorance in other quarters, they were fully acquainted with the whole state of the accommodation afforded to the sick poor in the Islington Infirmary, and at the end of twelve years, we are told in Mr. FARNALL'S report, that the Trustees *intend* to erect a new building!

#### ARE WE PREPARED FOR CHOLERA?

It has often occurred that medicine has been unjustly blamed for matters beyond its control. This has often happened in reference to cholera, a disease whose happily rare appearance among us prevents such frequent opportunities of scientific investigation as are obtainable in many other forms of disease. The outbreaks of this disease are generally comparatively sudden, and always so alarming that the public is ever ready to expect much from the profession and prone to run after the bold assertions of those who profess to have a specific remedy for the disease, whether those persons belong to the profession or not.

It would be as tedious as it would be useless even to enumerate the remedies that have thus been put forth as specifics for the disease in question. We would ask, is it not rare indeed that so much is expected from the resources of science or of art in any other disease, at least in more recent times? No one can boast of any specific for typhus, and in how few cases can we point to what may be regarded as a specific in any disease; even quinine itself, though so extremely valuable in many forms of intermitting fevers, requires to be judiciously handled, as otherwise its use may be attended with risk.

But while the public expect great and often indeed superhuman aid from the profession in times of alarming epidemics, there is but too often an absolute determination to do but little to remove those causes which are so generally proved to be productive of disease. Can we take credit to ourselves in many large towns for the cleanliness of our lanes and alleys, lodging-houses, or even for our streets? Is our supply of water good, and are our people taught the great importance of cleanliness in their dwellings, their persons, their clothes, and their cooking and water vessels, &c.?

Has it not been pointed out in the columns of THE MEDICAL PRESS AND CIRCULAR, and in those of our contemporaries, that overcrowding, bad and insufficient food, sour beer, unripe or bad fruits, and bad vegetables, &c., all tend to produce either cholera itself or forms of disease that too often end in cholera, and that appear as far as our knowledge at present extends, capable of producing that disease? Are not observers agreed that emanations from decomposing organic matters, excreta, &c., especially in connexion with moisture, are very prone to promote the disease and to form the suitable localizing conditions that tend to fix the disease in one locality more than in another?

Let us now consider the condition of our important city, that unfortunately is not possessed either of the means of some other British cities, nor of an adequate result for money that has been expended for the promotion of its sanitary requirements. We allude to Dublin,

and are reluctantly obliged to admit that too much appears to be expected from a naturally excellent climate. Were it otherwise the constituted authorities surely would not permit the existence of numerous plague spots in our midst. We would ask has the fever, which but too often exists endemically in Dublin, assumed so mild a type that official routine is to be permitted to pursue its usual course despite the many warnings given by the press and by concurrent events. Is the experience of past epidemics completely forgotten? and the fact, that has been published in various journals and brought under the notice of the Imperial Parliament—namely, that cholera commenced in 1854 in immediate proximity to one of the depôts of the city scavenging departments of Dublin, and that, radiating thence, lives were lost and sickness and misery were inflicted on the inhabitants of the neighbourhood and expense incurred in sick poor relief and in rates to support the widows and orphans of those who died. A work, entitled "A Report on Epidemics and Endemics," thus alludes to the circumstance: "Cholera broke out in a limited district in Dublin. The patients all lived near each other, and in their immediate vicinity there was a very large collection in a yard of street manure and night soil, collected by carts from the lanes of the neighbouring parts of the city."

Our readers will scarcely believe that, notwithstanding all that was done in drawing attention to that state of things at the time and repeatedly since, instead of improvement, matters in this respect have become much worse in proportion to the increase of live stock and of population in the city, &c.; so much so that we have seen within the last week that men were employed in constructing higher walls to give a greater capacity for the reception of the matters described above, although the depth of the accumulation of liquid and semi-liquid filth already exceeds ten feet, and in area upwards of an acre, and we speak of only one of many such depôts in the city of Dublin.

#### POISONED BLOOD.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the face of vast pretensions to accuracy of definition, and notwithstanding the imperious tone of some modern writers who affect to found all their notions of diseased action upon such phenomena as are alone capable of material proof, it would appear that there is still extant a haziness and uncertainty about the application of certain terms in medicine, which render their true meaning positively inaccurate, if not altogether false. I know of no illustration of this vice more glaring than that which at the present time exhibits all obscure constitutional disorders as arising from poisons. Thus we have the poison of cancer, of lues, of hydrophobia, of pus, of cholera, of typhus, *cum multis aliis*, recorded as the certain evidence of a specifically diseased or distempered blood; of which circumstance, however, no more certain sign or proof exists than the comprehensive and bold assertion of the observer—that because no better explanation can be had, therefore we must be content to say that the blood is "poisoned."

After all, this is probably only a reassertion of a dogma of some of the old humoralists; but inasmuch as it is now held up with an amazing tone of assurance by parties having some influence on occasions of grave social alarm, it may not be out of place to ask these worthies what they mean

exactly by a poisoned blood. John Hunter himself gives in to a very lax use of the term poison, as applied to the blood; yet in the same breath he admits that particular poisons select particular tissues—as the skin in small-pox or measles, the throat in hydrophobia, &c.

Mr. Abernethy had a profound belief in the efficacy of blue pill. Since his day —\* has had a moderately good innings, the late Dr. Chambers having been nearly the latest representative of that school in London. Now, however, the cry is once more—poisoned blood! Our cattle die of poisoned blood. The cholera is a poisoned blood. A pauper, or, for the matter of that, a sick rich man, falls into a purulent cachexy; the tendinous tissues are ploughed by sinus and repeated formations of matter; the man is pyæmic, his blood is charged with pus—it is poisoned! *Qui faire?* For if these things be so to the letter, the wonder is, not that so many die, but that anyone sick of a specific disease ever recovers.

With submission I desire to suggest to your readers that “poisoned blood” is not a satisfactory definition of the cause of death in a vast category of painfully fatal disorders. If it were so, we might as well shut up our books and instrument-cases, and take to some more honest calling than the practice of modern medicine and surgery.

It would be occupying your space unduly were I to attempt on the present occasion to trace the course of this “poison hobby.” Suffice it that it was largely aided, if not positively set a-going, by a kind friend and preceptor of my own, the late Dr. Robert Williams of St. Thomas’s Hospital, in Southwark, a very elegant scholar and most amiable man. His work on “Morbid Poisons” is extant and highly prized; but Dr. Williams was in medicine a sceptic, and brimful of theory not always of the safest kind. Be this as it may, I humbly ask now, as I would in the days of pupil-dom—What, Sir, do you mean by poisoned blood? I can appreciate the fact of an attenuated, a defective, an altered blood—a diseased condition, if you please—but not a poisoned blood. I believe that the fountain of life plays with a very unequal force, and that its waters vary infinitely as to the purity of their elementary constituents throughout the animal kingdom, but I have yet to learn that it suffers any admixture with other fluids with impunity. No: when such an offence is offered, like “the Old Guard,” it dies—but it does not surrender. Those which are termed, as I believe erroneously, symptoms of blood-poisoning, belong to one of two stages or periods of dissolution, when the action is destructive of life. The first denotes resistance, the second dissolution of the blood; but at no period does it submit with impunity to the attempted contamination.

In the last and most rapid act of fatal cholera we are not dealing with a diseased blood in the sense of poison, but with the dissolution and resolution of this fluid into its elements, in the vain effort to resist the inroads of a mephitic and death-dealing agent. Majendie’s celebrated remark—“I a commence pour la mort”—has seldom been appreciated in this its best and highest sense.

The subject is a large one and of abiding interest. I shall be pleased, at no distant time, to avail myself of your courtesy to add some additional remarks explanatory of much which is here but very obscurely rendered.—I have the honour to be your obedient servant,  
B. TRAVERS.

Dover-street, London, July 31, 1866.

#### THE “INFERIOR ARTICLE” IN DEMAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following impudent advertisement appears in the Poor-law column of the *General Advertiser* of Saturday, July 28:—

“KILLYBEGS DISPENSARY.—Wanted a Medical Officer for

this Dispensary. The salary is £40 per annum, with prospect of increase, and considerable private practice. Testimonials to be forwarded on or before the 8th August. Election will (D.V.) take place on Saturday, the 11th, at noon.”

Some months since I ventured in your columns to express my disapproval of the manufacture of an inferior class of practitioners by the Irish College of Surgeons. Moralists, and all who have the true interests of the profession at heart, will say I was *right*: although certain pseudo-political economists may as decidedly pronounce that I was *wrong*. “There is a demand for the inferior article,” they will aver, “and therefore there will be a supply.” Yes; but it does not follow that there *ought to be* a supply. However, passing by all argument on the question of right or wrong, we cannot deny the humiliating fact, that at least a demand for the inferior article does actually exist. The above advertisement proves it. Whether in this case the supply will meet the demand must appear “(D.V.)” on the 11th instant.

And here let me protest *in limine* against this hypocritical use on such an occasion of the initials which I have quoted. The men who would sanctimoniously propose “(D.V.)” to inflict a forty-pound medical attendant on the poor, are just the men whom I should suspect of sanding their brown sugar, “(D.V.)”—wetting their tobacco, “(D.V.)”—watering their rum, “(D.V.)”—or opening their iniquitous election proceedings at Killybegs on the 11th inst. with a hymn. It is, to be sure, some trifling consolation to humanity to find that those individuals have exhibited a degree of decent shame in concealing their names. The advertisement appears without either signature, reference, or even a date.

The Killybegs Dispensary Committee seem to have some glimmering idea that the proposed salary is *rather* too low to tempt even the lowest class of medical men to accept it; and, accordingly, a “prospect of increase,” and of “considerable private practice,” is thrown out as an additional bait; whilst the usual phrase, “exclusive of registration and vaccination fees,” is ominously omitted. Translated into plain English, all these attractive expressions signify merely this—and no more—viz., that if the medical officer occupies a portion of his spare time in sweeping chimneys, breaking stones, cleansing sewers, or any other description of work, he will be paid something for his labour. Of course he will—no doubt about it. But what upon earth has this to do with attendance on dispensary patients, where special duties have to be performed, and for which duties a specific—though too often an inadequate—salary is paid?

A word more about this “considerable private practice” in *nubibus*. The word “considerable” is relative as well as illusory. What might be thought considerable in a fishing village or coast-guard station on the wild shores of Donegal, would appear very *inconsiderable* in more civilized districts. It may be that in Killybegs another “£40 per annum,” realized in private practice, would be looked upon as something very “considerable” indeed.

Now, my object in all I have said is not to complain that the fishermen and hucksters of Killybegs have offered an additional insult to medical men, or inflicted an additional grievance on the profession. The injury which they contemplate is directed against the *public* and against the *poor*. The injury from which the profession suffers has been inflicted by members of its own body, and more especially by the various licensing corporations. So long as these corporations will persist in gratifying the demand for a very inferior class of medical men—and so long as medical men themselves will accept the paltry salaries offered by sordid, unfeeling dispensary committees and boards of poor-law guardians—just so long will those committees and boards

\* We are unable to decipher this name in our Correspondent’s MS.

seek to recommend themselves to the favour of penurious ratepayers by entrusting the helpless poor to the tender mercies, and more than questionable skill, of forty-pound doctors. The committees and boards do not, as a rule, mean to insult or aggrieve the medical profession. Impelled by false notions of economy, and stupidly ignorant of the real wants of the community, they seek for cheap doctors, and (*proh pudor!*) they find them ready-made to their hand. They conclude—and very naturally, according to their lights—that the medical man who accepts a salary of £40 a year is a competent judge of the value of his services, and that if he be not worth less than that sum, he is certainly worth no more. A sad state of things, it must be confessed, but who's to blame?

Here is another advertisement (slightly abridged), cut from the same paper which contains the Killybegs manifesto:—

“WANTED A NIGHT-STOKER AND GASFITTER, at the T.—GAS WORKS. Security required: perfect sobriety indispensable. Testimonials to accompany the respective Tenders. Wages per week from 17s. 6d. upwards, according to competency.”

Country gas companies are composed of a class of men pretty equal in intelligence to the average poor-law guardian, and yet we see that they pay their stoker £45 10s. per annum, and “with prospect of increase,” too. Why do they do this? Simply because they know that they cannot get a competent stoker for less. And also, perhaps, because in the case of the stoker “perfect sobriety is indispensable,” and “security is required”—qualifications not insisted on by the Killybegs Committee, who may not consider them as worth the extra £5 10s. of wages. Let it be borne in mind that, in reality, the difference between the remuneration of the stoker and of the medical officer is much greater than this. The stoker can appropriate and enjoy *the whole of his wages*; the poor unhappy doctor cannot touch a penny of *his*. The whole of his pitiful salary must be consumed in defraying the necessary expenses of his duties, and he must perform those duties for *absolutely nothing*. Attendance on a dispensary district in the rocky wilderness of Donegal involves the keep of at least one horse; and everybody knows that the maintenance of a horse and groom, with the consequent “wear and tear,” shoeing, farriery, &c., costs more than £40 a year.

A quizzical friend at my elbow suggests that the first of the above advertisements is nothing more than a hoax;—that some rustic wag, designing to caricature the cheese-aring practices of the Killybegs Dispensary Committee, seeks to attribute to them a conspiracy to spare the pockets of the ratepayers at the risk of the health and lives of the poor patients—insinuating, in fact, that they have devised a cunning plan to *kill the beggars* with the aid of a forty-pound doctor! Wicked, brutal, and far-fetched pun! The perpetration of such a sorry joke is incredible; and I must still adhere to my belief that the Killybegs advertisement, notwithstanding its anonymous character, is a genuine document.—I have the honour to be, Sir, your obedient servant,

EDWARD BEWLEY.

Edington, Clara, August 1, 1866.

#### EXAGGERATED REPORTS OF THE CHOLERA IN SOUTHAMPTON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read some extracts from Mr. Simon's report to the Privy Council in your issue of the 25th ult. Assertions and assumptions abound, but are they supported by facts? I am unable to discover them. Having been in extensive practice at Southampton for nearly a quarter of a century, and, with my partners, having had a full share of the cholera and choleraic cases during the present epidemic, I think it cannot be too generally known that exaggerated

reports have been *palmed* on some of the leading papers. I have seen but three cholera cases of a fatal character; one a policeman, *æt.* 66, who applied for assistance after severe diarrhoea had persisted for eight hours. He was then in collapse, and, although he rallied for a time, sunk at the end of twelve hours. The second, a porter, *æt.* 40, who had been under medical treatment for disease of liver for several years. He had taken his ordinary dose of active aperient medicine, and regarded his symptoms as due to the excessive action of his usual remedy. On returning from his day's work he fainted, and then his medical attendant was summoned. It was too late; extreme collapse had set in, and the poor fellow succumbed before the middle of the following day.

The third case was that of a widow, a green-grocer, *æt.* about 48. She had long suffered from chronic phthisis, and had been taking morphia daily for some time. Again the premonitory symptoms had been neglected, and she sunk in about twenty-four hours.

Although from seventy to ninety patients are seen daily, and a large proportion of them suffering from abdominal symptoms, only three others have died from choleraic disease, and not one since July 15. Those did not fall under my observation.

I really consider such facts most encouraging, the disease being fatal only among the aged, the diseased, or the very young—if treatment be resorted to in the early stage. It should be impressed on the public that the disease is neither infectious nor contagious; that it is curable with greater certainty than most other diseases (if treated prior to the stage of collapse—and that collapse from other causes is equally fatal with that from cholera)—that every family should be provided with some *powerful* astringent medicine, in order that no time be lost in the premonitory stage, as during the night, &c.; and that more than ordinary caution should be observed in excluding everything of an unwholesome quality from the culinary department. The frequent removal of all surface refuse should be carefully attended to; and absolute cleanliness, so far as drainage and water supply will permit, which, unfortunately, in many populous localities, is abominably defective, should be rigorously observed. The disease appeared almost simultaneously in several parts of the town, in the same ill-ventilated, low, dirty localities as were first attacked in 1849. All evidence of personal importation is wanting.

The report in to-day's *Lancet*—“from our own Correspondent”—is a disgraceful exaggeration. The deaths have been confined to the dirtiest and worst parts of the town, or places on their borders; in fact, the same localities where the disease proved so much more fatal seventeen years ago, and which could have been rendered healthful, and incapable of supplying the requisite pabulum for cholera, had the local authorities listened to reason, and supported the measures propounded again and again by sanitarians, instead of which they allowed them to stand alone, and decried their measures as too costly; but now, panic-stricken, they are scattering the public money broadcast.

The cholera hospital is opened on the brink of the mud, in about the lowest situation in the town! The ice-bag application has been vigorously pushed, and is now absolutely discarded, after having received a questionable amount of puffing! The injection into the blood of such acrid things as corrosive sublimate, turpentine, &c., are now being strongly recommended!

That fifty per cent. of those who have been attacked with choleraic disease have died, is simply a perversion of fact. Unless among the aged, very feeble, or diseased, none resists treatment, if remedial measures are resorted to in the premonitory stage.

There were other things in to-day's *Lancet* which, if they

did not instruct, must have amused its readers. It assured us that "while much was already known of the epidemic, much remained to be made out, both in regard to the mode of its progress and the best treatment to be pursued. The Government so far acted upon these views as to join France and other great powers in an attempt to ascertain with certainty the place of origin of the present epidemic, and to come to some plan for trying to confine the disease to its home, whenever again it should show a tendency to assume epidemic proportions." Now, surely, if the word epidemic be correctly construed, it would be quite as logical to insist on confining the winds and the waves to their home as any epidemic disease. I now enclose a copy of second issue of "Cholera Non-Contagious," &c., with some new matter. You did not favour me with a notice of my first issue. I have been, in years past, a frequent contributor to the *Circular*, and certainly one of your oldest and staunchest supporters, having taken it from its first number, and having every copy of it at hand. My partzers now do the hard work, so that I have a greater amount of leisure than of yore, and, should you regard my contributions as acceptable, you may depend upon me as a tolerably frequent communicant.—Faithfully yours,

EDWIN HEARNE.

Southampton, July 28th, 1866.

P.S.—The amount of choleraic disease at the present time is nothing compared with what the town suffered in 1849.

#### POOR-LAW MEDICAL REFORM ASSOCIATION.— VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Many of my medical brethren will have seen with regret that the Vaccination Bill has been withdrawn, but your readers may not be aware of the cause. It will be in the recollection of all that the Vaccination Bill was brought in as a Government measure, and framed by Government officials; but as it contained many objectionable clauses, and made no provision for the better remuneration of the medical officers, I addressed a pamphlet to each member of Parliament on the subject, and suggested certain remedies. My views were, through the medium of your journal, made public, and so much opposition was raised in Parliament by the profession, that the Bill was referred to a Select Committee, to whom I sent copies of the amendments proposed by us, and the result was, that a large number of the clauses were amended, and the Bill, had it become law, would have given the profession some twenty or thirty thousand pounds per annum more than they now have. The measure was not perfect, but I considered it would be most unwise to offer any further opposition to a Bill which had the sanction of a Select Committee of the House, and which would be of material benefit to the public, as well as to our profession, and unopposed would pass into law. Judge, therefore, my surprise, when, on July 21st, I received a letter from Dr. Gibbon, with a printed heading, "Metropolitan Counties Branch of British Medical Association—Parliamentary Committee," asking me to oppose the Bill, at the same time enclosing printed reasons against the fines and registration clauses contained in the Bill. Unfortunately for us the gentlemen composing this Parliamentary Committee, who seemed to have a *carte blanche* to do as they like, without consulting the members of the Association, raised such an opposition in the House that when the Bill should have gone into Committee on July 23rd, Mr. Corry withdrew it, saying "he had ascertained from hon. gentlemen on both sides of the House that the measure was likely to meet with great opposition, and it was therefore doubtful whether it could be carried through this year." I sincerely trust the Association at their next annual meeting will point out to their Parliamentary Committee that, whenever practicable, they should consult the members of the

Association before they take active measures to oppose Bills; and here permit me to say, I do not believe the Association as a body would ever dream of asking Parliament to do away with the registration of vaccination, without which the whole machinery must fall to pieces. I regret the loss of the Bill, as on the whole it was a good measure, and would have been of great benefit to the poorer portion of our profession—the Poor-law Medical Officers. I regret it still more, as it is the imprudent act of members of our own profession.—I am, &c.

RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, July 28, 1866.

#### ADELAIDE HOSPITAL.

DR. DUNCAN having resigned his post of Physician to the Hospital, the following letter was forwarded to him, and to which he sent the annexed reply:—

August 4, 1866.

MY DEAR DR. DUNCAN,—I am requested by my colleagues, the medical staff of the Adelaide Hospital, to convey to you their deep and sincere regrets at your recent resignation of the post of Physician to the Hospital. When it is recollected that during the long period of your connexion with the institution you were unceasing in your endeavours to promote its clinical, as well as general, interests, we cannot avoid the apprehension that we shall have much difficulty in replacing you.

One circumstance, however, tends to dispel the gloom the resignation has caused us—namely, that you were solely impelled to take the step, from the feeling that to do full justice to the clinical department of the hospital requires more time than the special professional subjects to which you more particularly devote yourself would allow of your giving to it.

In conclusion, I beg, on the part of the medical and surgical staff, that you will not altogether sever yourself from us, and will allow your name to be placed on the honorary list of Consulting Physicians to the Hospital.—I am, my dear Dr. Duncan, yours very faithfully,

B. WILLS RICHARDSON, F.R.C.S.I.

Dr. James F. Duncan, F.K.Q.C.P.,  
Upper Merrion-street.

8, Upper Merrion-street, August 4, 1866.

MY DEAR RICHARDSON,—Will you kindly convey to my late colleagues my sincere thanks for the letter I have just received. I gladly accept the proffered post of Consulting Physician to the Adelaide Hospital, and I rejoice to think that by this act, the connexion which has so long and so pleasantly subsisted between us shall still be maintained, notwithstanding the step I have been obliged to take.—Believe me, very sincerely yours,

J. F. DUNCAN.

Dr. W. B. Richardson, Secretary  
to the Medical Board, Adelaide Hospital.

#### THE CATTLE PLAGUE AND DISINFECTANTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Your correspondent "M.D." disagrees with Mr. Crookes, Dr. Angus Smith, and myself, for advocating the use of carbolic acid as a disinfectant.

He objects to the first-named gentleman's report, because most of the experiments detailed are in connexion with carbolic acid, but seems to forget that Mr. Crookes expressly states that he experimented with chlorine, ozone, sulphurous acid and the tar acids. "These," says Mr. Crookes, "are representative bodies, and numerous trials have been made with them before coming to a conclusion as to their respective merits." I cannot see what deodorizer or anti-septic (if we, perhaps, except chloride of zinc) would not come under this category. As regards the other remarks upon Mr. Crookes' report, it behoves that gentleman to reply to them, should he think it necessary.

"M.D." has a suspicion that it was in consideration of Mr. Crookes' report coinciding with my own views that I

had such a favourable opinion of it. Surely this requires no admission on my part—a corroboration of the truthfulness of my ideas upon this subject was calculated to confirm my opinion as to the correctness of Mr. Crookes'.

I shall be very happy to argue the relative merits of disinfectants from a chemical point of view, if "M.D." will appear in *propria personâ*, but otherwise I do not think it desirable to enter into a discussion with an anonymous correspondent.—Yours obediently,

C. R. C. TICHBORNE, F.C.S.L., &c.

Laboratory, 40, Mary-street, 6th August, 1866.

### THE ELIMINATIVE TREATMENT OF CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The contagion introduced from Liverpool seems to have been now confined to the members of the family first attacked, but with so many of the English ports infected, we can scarcely hope to escape from other importations. It is, therefore, most desirable that we should calmly consider and then decide upon the treatment of the disease which offers most chances of recovery. I am an earnest advocate of the eliminative treatment—that is, by emetics, purgatives, such as castor-oil or calomel, and saline injections. My experience of this plan is very limited, being confined to my observation of some cases in the cholera wards at Liverpool, and that of Mrs. Meyler (the only one of the City-quay cases which I was called on to treat). But I have been convinced by the admirable writings of Dr. George Johnson. That eminent physician most fully published his views in 1855 in his work on "Epidemic Diarrhœa and Cholera," but they received very little attention until the present outbreak threatened. His "Notes on Cholera" are most lucidly and forcibly written, and to me seem so unimpeachable on physiological or pathological grounds, that I think they cannot fail to bring conviction to an unbiassed mind. A shilling pamphlet just issued by Hardwicke for general circulation contains an epitome of the former work, and highly commendatory, a review of it which appeared in the *Saturday Review* from the pen of Sir Thomas Watson. I would also advise the perusal of Dr. Handfield Jones' paper in the *British Medical Journal* (May 5), as containing all possible objections to the eliminative plan which could be started, and of Dr. Johnson's reply in the following number of the same journal.

Treatment by evacuants is not new; on the contrary, it was almost the invariable method in India before the introduction of cholera into Europe, and my friends, Dr. Ross, surgeon, 92nd Highlanders, and Dr. Clarke, surgeon, 85th Regiment, lately informed me that their invariable plan, in many hundreds of cases in India and the West Indies, was to order a mustard emetic, followed by castor-oil and turpentine as a purgative. The former gentleman has promised to communicate his experience of the treatment in your next number. In many post-mortem examinations of cholera patients who have been treated by astringents, the alimentary canal has been found filled with the characteristic whitish excreta, which, as containing the poison, all advise should not be allowed to accumulate in drains. To use Dr. Johnson's expression—Is there not as much need to flush the intestinal sewer? I await anxiously the publication of the details of many modes of treatment employed in the cholera wards in Liverpool, which Dr. McCloy has promised, but it has already transpired that the eliminative has been by far the most successful plan.

The London College of Physicians, in their communication to the Lords of the Privy Council, just issued, recommend that "If the discharges become colourless and watery (the purging being of the kind commonly called rice-water purging), and be accompanied with vomiting and coldness, the opiates should no longer be persisted in."

In conclusion, I have but to explain that my object in writing this hasty letter has been to ask the serious attention of the profession to the eliminative plan, every aspect of which is most admirably discussed in Dr. Johnson's writings.—I am, &c.,

E. D. MAPOTHER.

### COUNTY AND CITY OF CORK MEDICAL PROTECTIVE ASSOCIATION.

A SPECIAL meeting, numerously attended, was held on Saturday last, consequent on an action brought against Dr. Poole of Ardmore, at the late Cork assizes, for alleged malpraxis, at which meeting an expression of deep indignation characterized the speakers, as well as all present; while universal sympathy was evinced towards Dr. Poole at being made the innocent victim of so outrageous a proceeding.

Several subscriptions, limited to ten shillings, were received in the room towards defraying the expenses of the action, and resolutions passed, which will be found in our advertising columns.

NOTE FROM THE LONDON EDITOR.—At page 131, column second, of our last number, it is alleged in an article headed "Notes of London Practice," "that something like twenty cases of a mild type (of cholera) have been seen at the London Hospital, and five deaths." This statement is entirely erroneous, as the first twenty cases admitted at the London Hospital were all, or nearly all, fatal; and in the succeeding week 120 deaths from cholera occurred at the hospital, and were reported by the Registrar-General. By some inadvertence which we are now investigating, and a recurrence of which we are taking steps to obviate, the article referred to was never submitted to the London Editor, who was perfectly cognisant of the real facts of the case, and by whom (if the article had been seen by him before its publication) the error would, it is almost needless to remark, have been at once corrected.

It is with much pleasure we learn that the Poor-law Board is about to appoint an additional inspector for the metropolitan district, and that this important post is to be conferred on Dr. Markham. This is as it should be. No one is so well qualified for an office of this nature as a medical man, and no one will doubt the fitness of Dr. Markham for the appointment. We have no doubt that in his new sphere he will soon add to his deservedly high reputation, and while we congratulate him on the recognition of the Government, we cannot help remarking that Mr. Gathorne Hardy may be considered fortunate to be able to secure such services as those of Dr. Markham.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a board of examiners, held on the 1st inst., the following members of the college passed their examinations, and were admitted licentiates in midwifery, viz.:—William Folkes, Dukinfield; William John Wey, Plymouth; George Othwaite Spencer, Upper Gordon-street; William John, Haverfordwest; William Monckton, Brenchley, near Tunbridge; Joseph Loane, Dock-street, Whitechapel; John Quick, Penzance; Charles George Edmonds, Southampton-street, Camberwell; Richard Holt Robinson, Manchester; George Moore, Birmingham; Thomas Bell Hay, L.S.A., Caledonian-road; Richard Matthews Pryce, L.S.A., Caersws, Montgomeryshire; Richard Cresswell, Lewisham; William Harris Butler, Old Charlton, Kent; and John Macdonald, Kidderminster (not a member).

THE CATTLE PLAGUE.—By the weekly return for the week ending Saturday, July 21, the number of attacks in Great Britain was 207—viz., 195 in England, 11 in Wales, and 1 in Scotland. 150 sheep are reported during the week to have been attacked, making a total to this date, 5596.

**SIR CHARLES HASTINGS, M.D.ED., D.C.L.OXON.,**

FOUNDER OF THE BRITISH MEDICAL ASSOCIATION.

FOR most of the following particulars relating to Sir Charles Hastings, we are indebted to a biographical sketch from the pen of the late Dr. Herbert Barker:—

Six or seven years after the commencement of this century, if anyone had seen a playful schoolboy, rejoicing in rambles along the pleasant river Teme, and watching grayling rising for flies, it would have seemed too improbable to predict that the truant would, some day, be known as the most eminent medical man in his county, and as the founder of an association destined to raise the character of the medical profession. The boy was the sixth son of the Rev. James Hastings, rector of Martley, and was born at Ludlow, on the 11th of January, 1794. He attended the grammar school at Martley where he made no great progress in learning, and was soon afterwards sent to study medicine under the care of Messrs. Jukes and Watson of Stourport. After a few months of comparative indolence, a passion for study and a resolution to rise in his profession were almost suddenly developed in him, and his subsequent conduct proved how easily he could redeem what had seemed lost time in his boyhood. At the early age of eighteen, he was elected to the office of House Surgeon to the County Hospital, and fulfilled its duties so well as to win the confidence of those who, on the ground of his inexperience, had opposed his election. In this situation he had the good fortune to become acquainted with Dr. Wilson Philip, by whom he was employed in making a series of experiments on the functions of the cerebral, spinal, and ganglionic systems of nerves, and, especially, on the effects of galvanism in producing the results of nervous energy.

These studies served to give Mr. Hastings some status in the University of Edinburgh, where he matriculated in 1815. It so happened that, on the first evening of his attendance at the Royal Medical Society, the subject of discussion was so closely related to his recent course of experiments, that he was able to speak upon it so as to deserve attention. He now industriously attended several courses of lectures, and was favoured with the friendship and esteem of Dr. Monro. After a short interruption of studies, on account of delicate health, he returned to Edinburgh, and devoted himself to microscopic observations with regard to the several doctrines of physiologists on the irritability of the bloodvessels. At that time, he was the only student in the University who made use of the microscope in such investigations, and, subsequently, when he read before the Royal Medical Society a paper giving the results of these observations, the paper was censured by certain authorities, because it was founded on microscopical data, which were declared to be inadmissible!

Meanwhile, he had been unanimously elected President of the Medical Society (1817). In his thesis, written near the close of his academical career, before receiving the doctorate, he adhered to his favourite subject, "*de vi contractilium vasorum*," and gained the recommendation of the professor of anatomy. A proposal that Dr. Hastings should succeed Dr. Gordon, as teacher of Anatomy and Physiology, was declined, on the ground of delicate health, and to escape from the harsh winters of the North, Dr. Hastings removed, in 1818, to Worcester. In the same year he was appointed Physician to the Hospital in that

city, and continued to discharge the duties of that office during the period of almost half a century. His leisure hours were occupied in revising his observations on the action of the bloodvessels, and in recording and studying the numerous cases of affections of the mucous membrane treated in the course of his practice. As the results of these studies, he published, in 1820, a "Treatise on Inflammation of the Mucous Membrane of the Lungs," with introductory essays entitled, respectively, "An Experimental Inquiry into the Action of the Bloodvessels," and "An Inquiry into the Nature of Inflammation."

Dr. Hastings had long observed, with regret, the want of efficient means of promoting union, for both scientific and social objects, among provincial medical men. His first endeavour to supply this want was by the publication of a quarterly journal, under the title of the "Midland Medical and Surgical Reporter" (1828). It was well supported by contributors and subscribers, and its founder published in its pages, among other papers from his pen, an essay on the "Medical Topography of Worcestershire." Dr. Hastings was subsequently led to contemplate something more than a journal. He proposed the formation of an association for the promotion of the following objects:—the collection and publication of recent medical information; the study of medical topography, in connexion with endemic and epidemic diseases; the advancement of medico-legal science; and—last, but most important—the maintenance of the honour of the profession. This proposal issued in the formation of the Provincial Medical and Surgical Association. Its first meeting was held in Worcester, on the 19th of July, 1832, when Dr. Hastings delivered the inaugural address. The Committee prepared memorials to Government and petitions praying for the introduction of measures to provide for the better organization of the profession, and recommending uniformity of primary qualifications, equal rights of practice, and the adoption of the representative system in the formation of councils. Such were the plans that have resulted in the establishment of the British Medical Association of the present time.

The office of joint secretary to the Association was held by Dr. Hastings until 1843, and, on his retirement, he was appointed permanent president of the council and treasurer. In compliance with the wishes of many of the leading members, the honour of knighthood was, in 1850, conferred on him. In 1839, at the meeting held in Liverpool, the members of the Association, anxious to confer on Dr. Hastings some lasting token of regard and gratitude, presented a portrait of him to his wife. At the Annual Meeting of the Association held in London in 1862 a resolution was passed by the Council to offer a prize Gold Medal to the writer of the best essay on a subject connected with the medical profession—the medal to bear the profile of Sir Charles Hastings, and to be called the Hastings Prize Medal.

On the 9th of January, 1862, a meeting was convened at Worcester, to present to Sir Charles Hastings a splendid testimonial, commemorative of his *forty-nine* years of service as Physician to the Infirmary.

The study of natural history also supplied for Sir Charles a favourite recreation amid more arduous pursuits, and the excellent Museum in Worcester owes mainly its existence and success to his exertions. In 1834 he published "Illustrations of the Natural History of Worcestershire," and, subsequently, an account of the Salt Springs of the

same county. This latter publication supplied a great part of the materials used by Sir Roderick Murchison, in treating the same subject, in his celebrated work on the "Silurian System."

Sir Charles Hastings had for some time been in delicate health, and about two years ago his death was daily expected. He, however, recovered in some degree, but eventually expired at his residence near Malvern in the 73rd year of his age.

## REPORT OF THE COMMITTEE ON CHOLERA.

APPOINTED BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE Committee appointed by the College to consider a letter addressed by the Lords of her Majesty's Privy Council to the College, relating to the expediency of issuing instructions to captains of merchant vessels, "how they should act when proper medical attendance cannot be procured, so as to provide for the health of their crews against attacks of cholera," beg leave to report as follows:

"Their lordships request to be informed whether in the opinion of the College, any, and if so, what suggestions might be issued as representing the present state of medical knowledge and experience with regard to the drugs which should be given, or other treatment which should be adopted, in attacks of cholera, and especially in the beginning of the disease, when proper medical attendance cannot be procured." Their lordships at the same time submit to the College a copy of the instructions issued on previous occasions.

"With reference to that part of the instructions on which their lordships particularly request the opinion of the College—viz., that which relates (1) to the necessity of avoiding purgative medicines during the prevalence of cholera; and (2) the measures to be adopted when cholera appears on board ship, the Committee think—

"1. That when opening medicine is required, the mildest should be selected, as castor oil or rhubarb. Glauber's salts and Epsom salts are dangerous. The common belief that prolonged costiveness should not be interfered with during the prevalence of cholera is erroneous.

"2. That the master should ascertain by inquiry, morning and evening, whether any of the crew are labouring under such looseness; and if so, the following recommendations are subjoined for his guidance.

"3. That the remaining instructions should stand as follows:

"If a man be attacked with looseness of the bowels, he should, whenever it is possible, be sent to bed and kept warm, and some aromatic and astringent medicine, containing a small quantity of opium, should be given to him at once, and should be repeated every hour or two, according to the severity of the purging.

"It is suggested that ten grains of the aromatic powder of chalk and opium (of the British Pharmacopœia) should be so given in half a glass of peppermint water, or weak brandy and water. Should this medicine not be at hand, five measured drops of laudanum may be substituted for each dose of the powder.

"Large doses of opium, or of ardent spirits, should be avoided.

"If the looseness should result from bad or obviously indigestible food, or if the discharges are unnaturally offensive, and attended with griping pain, it would be desirable to give a dose of either of the gentle laxatives above-named before administering the opiates.

"The diet should consist mainly of beef-tea or broth, gruel, or rice.

"If the stools become colourless and watery (the purging being of the kind commonly called 'rice-water purging') and be accompanied with vomiting and coldness, the opiates should no longer be persisted in, and spirituous

liquors should be avoided. The patient should be strictly kept in the recumbent position, he should be allowed to drink water freely, and should be abundantly supplied with fresh air. Warm applications should be used to the feet and legs, and a mustard poultice should be applied to the pit of the stomach. Cramps may be treated by rubbing the affected parts with the warm hand.

"In all cases, medical advice, when obtainable, should be obtained as soon as possible.

"The Committee would further suggest that, in addition to the instructions relating to over-crowding, dampness, filth, unwholesome food, and excess, on which they make no comment, believing that they will be revised and amplified by their lordships as advised by their medical officer, regulations ought to be made for the guidance of ship masters on entering or leaving an infected port.—Signed on behalf of the Committee,

"WILLIAM W. GULL."

## Parliamentary Intelligence.

HOUSE OF COMMONS.

JULY 26.

MEDICAL OFFICERS OF THE ARMY AND NAVY.

ON the vote of £5926 for increased pay and allowances to the medical officers of the army and navy,

Mr. CHILDERS observed that the medical officers of the army and navy appeared to be taken out of the body of young medical men in this country, no provision being made for educating them for the services with the exception of a few months' training. He had felt it his duty to read very carefully the evidence taken by the committee appointed to consider the case of those officers; and it appeared to him that they did not complain so much of the inadequate amount of the pay given to them as of the inconvenience to which their status in the services put them. They also looked forward to retirement on pensions after fifteen or twenty years. Now, it could not be satisfactory to the body of combatant officers that the medical officers, who entered the service at about the same age as they themselves became lieutenants, should receive so much higher pay, and should be able to retire at an early age on so much better terms. He would suggest to the right hon. gentleman the Secretary of State for War, and his right hon. friend the First Lord of the Admiralty, that during the recess they might consider whether, instead of taking their chance of selecting from a body whose ideas of remuneration and early retirement were pitched so much higher than those of the combatant officers, it would not be wiser by early education to train up a body of medical officers, who would look to the army or the navy as their profession for life.

General PEEL thought that if there was one thing more desirable than another in connexion with this subject it was to obtain for the army and navy the best medical men they could procure (hear, hear). In 1858 a warrant was issued and very soon after it underwent an alteration in consequence of the dissatisfaction expressed with it. The hon. gentleman (Mr. Childers) now appeared to be dissatisfied with the amended warrant; but he would ask the hon. gentleman how could they possibly expect medical gentlemen to enter the army or the navy if it was announced to them that their status was going to be altered?

Mr. CHILDERS begged to say that his suggestion did not apply to gentlemen who had entered. It was entirely prospective.

General PEEL would remind the hon. gentleman that under the existing warrant direct inducements had been and were still held out to medical students to qualify themselves for the army and navy. The result of the alteration made in the terms of the minute had not been to attract the number of candidates anticipated, for at the present moment there were actually more offices to fill, he believed, than candidates for those positions. The effect of the proposal now put forward he understood to be that instead of inviting the services of members of the profes-

sion generally, a set of young men were to be sought out from some special Government establishment. He had not enjoyed the opportunity of considering the proposal as it might affect the navy. But it certainly ought to be the object of the House of Commons to secure for the army and navy the best men that could possibly be got (hear).

Mr. HENLEY said as far as he could gather from the statement of the hon. gentleman opposite it was proposed that young men should be attracted to the service by some scheme of early retirement. In that case young men would learn their business in the army or navy, and as soon as they knew it, would be enabled to retire and earn more money elsewhere (hear, hear).

Mr. CHILDERS said the right hon. gentleman exactly reversed the effect of his proposition (hear, hear).

The vote was then agreed to.

## Notices to Correspondents.

J. H. B.—In our next.

D. F.—The paper mentioned has not come to hand.

Medicus.—Your supposition is well founded.

F. R. S.—Shall receive a private note.

## Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College, at a Meeting of the Court of Examiners on the 26th inst. :—

Carruthers, James Gurney, Northampton.  
 Chester, John Charles, Redruth, Cornwall.  
 Coombs, Rowland Hill, Bedford.  
 Hallett, Lyttleton, Bedford-place, Russell-square.  
 Harris, William, Carshalton, Surrey.  
 Hayne, Frederick Greaves, Northfleet, Kent.  
 Marsh, Thomas Charles, Brixton, Surrey.  
 Moore, Joseph, M.D., McGill College, Montreal, Canada.  
 Norris, Henry Frederic, Charmouth, Dorsetshire.  
 Pryce, Richard Matthews, L.S.A., Caerseos, South Wales.  
 Rumsey, John Henry, Fulham.  
 Smith, Samuel Hignett, L.S.A., Weaverham, Cheshire.  
 Taylor, Henry Shinglewood, Alton, Hants.  
 Waller, John, Tattingstone, near Ipswich.  
 Williams, Evan, Llechlech, North Wales.  
 Young, Frederick William, Salisbury.

At the same meeting of the Court Mr. Thomas Roche of the Royal Naval Hospital, Haslar, and Mr. William Shute Fisher, M.B. Dub., of the Royal Marines' Infirmary, Woolwich, passed their examinations for naval surgeons. These gentlemen had previously been admitted members of the College, their diplomas bearing date respectively 24th of July, 1854, and 12th of June, 1857. It is stated that of the 72 candidates who presented themselves for examination 15 failed to acquit themselves to the satisfaction of the Court, and were consequently referred back to their hospital studies for six months.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 26th ult. :—

Anderson, David Hawley Burn, Edinburgh.  
 Beales, Benjamin Dawson, Queen's College, Birmingham.  
 Connock, Charles James, Mount-street, London.  
 Dolan, Thomas Michael, Cashel, county Tipperary.  
 Jackson, Frederick William, Broadstairs.  
 Schuetté, Rudolf, Gottenen.

The following gentlemen also on the same day passed their first examination :—

Guy, John, Guy's Hospital.  
 King, David, King's College.  
 Lane, William Wingate, St. Bartholomew's Hospital.  
 Wallace, Frederick, Guy's Hospital.

DEATH IN THE TRAIN.—In the Indian railway trains a considerable number of passengers are found dead in the carriages. Death is supposed to be caused by the effects of the great heat upon persons who undertake journeys and religious pilgrimages when physically unfit for the exertion.

THE CHOLERA IN DUBLIN.—LATEST PARTICULARS.—TUESDAY MORNING.—Another fatal case occurred at half-past eleven on Monday night, at 18, Poole-street. The deceased, a woman aged 32, was attended by Dr.

Ryan. There is no communication traceable to the site of the former cases, and it therefore appears to have been spontaneous. The room has been emptied and fumigated, but there is more personal need for the establishment of some place of refuge for the families of those attacked.

## WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING AUGUST 4TH, 1866.

By J. H. STEWARD, Strand, and Cornhill, London.

| July, 1866. | Barometer reading reduced to 32 degrees. | Thermometer. |       | Dry bulb. | Wet bulb. | Wind.      |        | Rain. | Remarks. |

## CHOLERA.

### Carbolic Acid Disinfectants. McDOUGALL'S PATENT DISINFECTING POWDER.

Carbolic Acid was first introduced as a disinfectant for public and household purposes as one of the active ingredients of this celebrated Powder; also containing Sulphurous Acid, the Powder combines the highest deodorizing and antiseptic qualities.

McDOUGALL'S PATENT DISINFECTING FLUID is prepared from the Powder, and is useful for purposes when a Powder may be inconvenient.

McDOUGALL'S PATENT DISINFECTING SOAP pleasantly and without the possibility of injury, conveys Carbolic Acid to the Skin, giving protection to attendants and visitors to the Sick from contagion. Bed and body linen rendered innocuous if washed with it.

McDOUGALL'S MEDICAL CARBOLIC ACID.  
 McDOUGALL'S PREPARED CARBOLIC ACID for Sewers and Drains.

Sold by Chemists, Oilmen, &c.

ALEX. McDOUGALL.

London: 11, Arthur-street West, London-bridge.

Manchester: Riga-street Shudehill.

\*.\* Write for "Suggestions for Prevention of Cholera."

ESTABLISHED 1812.

FOR the Sale of LEECHES and all kinds of MEDICAL HERBS. H. POTTERS, Depôt, 65, Farringdon-street, London, E.C. His new priced Catalogue sent to any address on application. H. P. has on Sale all kinds of Turkey and Honey-Comb Sponges.

TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

**Brown's Cantharidine Blistering Tissue,** prepared from pure Cantharidine. An elegant preparation, vesicating in much less time than the Emp. Lyttæ, P.L., easily applied and removed, and will not produce strangury or troublesome after-sores. It has received the sanction and commendation of many of the most eminent practitioners in the kingdom.—In tin cases, containing ten feet, 6s. 6d.; and small cases of five square feet, 3s. 6d. each.

BROWN'S TISSUE DRESSING.

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, Burns, &c., and may be called a companion to the above.—In tin cases, containing twelve square feet, 1s. 6d. each.

Sole Inventor and Manufacturer, T. B. BROWN, Birmingham. Sold by all Wholesale and Retail Druggists and Medicine Agents throughout the British Empire.

Dublin Messrs. BOILEAU and BOYD, 91, 92, & 93, Bride-street.

**James's Fever Powder, 4s. 6d. per bottle; packets 2s. 9d. each.**

Prepared and sold by J. L. KIDDLE, 31, Hunter-street, Brunswick-square, London.

This Preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remark on the part of the Proprietor unnecessary. To be had of all Wholesale Druggists.

**White's Saccharized Hydrate of Magnesia.**—For INFANTS and FEMALES it will be found an invaluable Medicine.

From its agreeable and pleasing taste, it has the advantage over other preparations of Magnesia, as the most susceptible stomach not reject it.

SOLE MANUFACTURERS AND PROPRIETORS,

BOILEAU and BOYD,

Wholesale Druggists and Manufacturing Chemists,

91, 92, and 93, Bride-street, Dublin.

Wholesale Agents:—Barclay and Sons; Newbery and Sons; S. Maw and Son; W. Edwards, London; Raines and Co., Liverpool, Edinburgh, and York; Bewley, Hamilton, and Co.; the Apothecaries' Hall; Dr. Butler; George Oldham and Co., Dublin; Grattan and Co., Belfast.

Sold in bottles at 1s. and 2s. 6d. each; also in Winchester Quarts for Dispensing.

### ON THE TREATMENT OF CHOLERA.

By A. C. ROSS, M.D., M.B., L.R.C.S.E., L.M.Ed. M.Ph Soc.,  
SURGEON, 92ND GORDON HIGHLANDERS.

HAVING been urged by some of my professional brethren to state my views on the subject of cholera, I do so the more readily as I conceive every medical man is bound to give the result of his experience to assist the profession in deducing from a variety of treatment some general principles to guide them in the treatment of this dread disease. About nine years' service in the West Indies, India, and China (during which I have seen several epidemics of this disease), and a personal experience of it, may entitle me to offer an opinion on the subject.

The limits of your space must preclude my entering into extended details in illustration of my views; but I wish it to be understood, that I do not desire to dogmatise, nor insist on my opinions being the only correct ones on the subject. The opinions I advance, I shall illustrate with facts, as far as my memory will serve me.

Before entering into any details of treatment, I would offer a few general observations.

I would desire to warn all against these great enemies of mankind—especially when an epidemic of cholera is apprehended—I mean fear, filth, and unripe fruit, or unwholesome food of any kind. We are all familiar with the effects produced on the urinary organs and often on the bowels by what is vulgarly denominated a "howling funk;" and many of us are familiar with the allegorical dialogue between the good spirit and cholera, who, when upbraided by the former for killing so many, replied: "I killed but one, fear slew the rest." During the fearful epidemic of cholera, which decimated the island of Barbadoes in 1854, many instances of men being prostrated by fear came under notice. One case will suffice:—A mess-waiter while employed in the pantry, heard of the death by cholera of a female friend of his, he instantly dropped down, his face a picture of abject terror and despair, was seized with vomiting and purging, taken to hospital, and died. Many of the men, and even non-commissioned officers, were stricken with terror, even found weeping in their barrack-rooms, and were attacked by the symptoms of the disease; while, on the other hand, the medical officers and hospital attendants who were in attendance and contact with the sick, both by day and night, who breathed the same atmosphere, and whose clothes were often covered with the vomit of the patients, enjoyed a singular immunity from the disease.

It is a trite saying, that cleanliness ranks next to godliness; not cleanliness of the person alone, but of the house and all its surroundings. Any epidemic of cholera, typhus, &c., is certain to be most severe among the poorer classes and the "great unwashed," whose persons are such strangers to the luxury of soap and water, and whose houses are dirty, ill-ventilated, and too often surrounded by filth and refuse of every description. At such a time as this, every effort should be made to induce and assist the poor to wash themselves frequently, to cleanse and whitewash as far as possible their houses, and to remove all refuse and filth. Many people may pooh-pooh all this, like the worthy alderman, who, at a public meeting, snapped his fingers at all sanitary arrangements, and triumphantly declared he had not washed his body for

five-and-twenty years, and yet was as healthy as any one present. I will give but one instance in support of my opinion. Cholera broke out in the station where my regiment was quartered in India. I soon remarked that one company furnished, if I recollect correctly, as many cases as the rest of the regiment. After careful inspection I found that near the block of buildings occupied by that company, there was a heap of rubbish, consisting of straw and decayed vegetables, &c., lightly covered with earth and rank grass. This was at once removed, lime and fresh earth thrown down, and that company at once became the healthiest in the corps.

Unripe or overripe fruit, raw or decaying vegetables, putrefying fish or meat, and salted fish or meat, if too frequently used, will certainly cause derangement of the digestive system—a derangement which may at present rapidly merge into cholera. Fruit should be eaten ripe, and free of the coarse rind, vegetables should be fresh and well cooked, and fish and flesh should be quite fresh and simply cooked.

Before proceeding to consider the symptoms and treatment of cholera, I would direct attention to a few simple and useful rules to be followed by all. If cholera unhappily appears, lay aside all fear; attend to the cleanliness of your house and person; remove all accumulations of filth of every description; avoid exposure to wet and cold; if wet, rub yourself dry, and change as quickly as possible; if cold, take exercise, and if possible a warm drink; avoid going into a sick room with an empty stomach; if you cannot command some solid food, or a cup of tea or coffee, take a small quantity of good whisky or brandy and water, rinsing your mouth with it first; when you leave, wash your hands and brush your hair.

On the non-professional sufferer I would urge the necessity of prompt application for medical advice as soon as symptoms of sickness or purging set in. It may be that these arise from over-indulgence, or from eating some deleterious article; if so, the mischief is readily removed, and the fears of the patient are allayed. If unhappily the symptoms are those of the dread disease, then the physician and patient have a better chance, for every moment is of vital importance.

Many and various have been the opinions expressed with regard to this disease and its treatment, and as yet with but varying success. As yet, I fear, we can only hope to tackle the destroyer by treating symptoms as they occur, basing our treatment on sound principles deduced from reason and experience.

The eliminative mode of treatment, as recently propounded by Dr. George Johnson, modified by circumstances as they arise, appears to me the soundest in principle; I myself have adopted it for some years. Whether the disease is caused by the presence of a specific poison in the blood or stomach, or the presence of deleterious matter in the alimentary canal, it is certain that it is worse than useless to attempt the cure of the disease while the exciting cause remains. That the disease may be caused by some poisonous product being generated in the body or conveyed there in drink or food, would seem to be indicated by the fact, that I have frequently seen animalcules in a state of rapid motion on the field of the microscope, whenever I placed on it any of the vomit or rice-water evacuations, or the contents of the stomach, taken after the death of a cholera patient. On the other hand, I have known, during an epidemic, all the symptoms of the disease appear in the case of a military prisoner, deprived for months of animal food, as soon as he resumed his ordinary diet. In such a case the disease would appear to have been caused by the presence of food to which the stomach had not been for some time accustomed.

We have not yet arrived at that state of perfection in medicine which would admit of our saying that any special mode of treatment is alone correct. In cholera, we want to treat the symptoms, and must be guided by common sense in our selection of remedial agents. If the patient

applies for advice in the earlier stages of the disease, suffering from nausea or vomiting, violent griping pains, and purging, it will be clear that there is some mischievous agency at work, whether poison or unwholesome food. The initial treatment should therefore be directed to the expulsion of this agent. Therefore, an emetic should be given, followed, when the stomach is able to retain it, by a mild aperient. The safest, simplest, and most convenient emetic is a teaspoonful to a tablespoonful of mustard, mixed with warm water, and followed by copious draughts of tepid water till the stomach is completely emptied. The merits of mustard as an emetic are that it is instantly procurable, it acts rapidly, it gives a stimulus to the stomach, and sends a glow through the body; and it leaves behind it no feeling of nausea or depression, and does no harm even if it is not rejected. A scruple of sulphate of zinc will also have the desired effect. Ipecacuanha I would never use in this disease on account of the prolonged nausea and great depression it produces, dangerous results at a time when you want to prepare the stomach for other remedies, and where every moment is of so much importance.

The stomach being rapidly cleaned of its contents, and restored to a healthier tone by the mustard, is fitted to receive and retain the mild aperient which should follow. I myself prefer castor-oil to any other purgative in these cases, and I give it in doses of two or three drachms, combined with ten minims of tincture of hyoscyamus to obviate any tendency to griping. If a small quantity of mucilage is added to the oil, drop by drop, while the whole is rapidly stirred in a mortar, it is formed into a pleasant emulsion, which is readily taken by patients who would sicken at the sight of the pure oil. Two or three minims of oil of peppermint may be dropped on the surface of the draught. If this draught is rejected it should be repeated soon afterwards. In half an hour milk, barley-water, or weak brandy-and-water, or thin arrow-root, may be given to quench the thirst. Small bits of ice rolled about the mouth and afterwards swallowed will also relieve the thirst and allay the irritability of stomach; for the latter purpose a sinapism over the stomach is very efficacious. After the emetic, if the stomach refuses to retain either medicine or food, I have found a few drops of chloroform, hydrocyanic acid, or creasote in a small quantity of water, have the desired effect.

Having got rid of the irritating agents by emetic and aperient, our attention is next to be directed to the removal of the severe griping pains in the abdomen and cramps of the extremities, which accompany this disease; to allay the general irritability of the system; to keep up a healthy action of the skin and a proper warmth of the body; to stimulate the circulation, which is so apt to stagnate; and to restore the alimentary canal to a healthy tone and action. The pains may be relieved by the application of sinapisms, flannels soaked with turpentine, or of tins containing boiling water, to the abdomen, and by friction with the hand to the extremities. The other results should best be obtained by the exhibition of diaphoretics, sedatives, diffusible stimulants, and aromatics, of such kinds and in such proportions as the physician may like best. I myself have used with great benefit the following mixture, occasionally varied as circumstances may require:—

℞ Chloroformi, ℥ss.  
Sp. ammon. aromat. ℥iii.  
Tr. opii, ℥i.  
,, cardamom co. ℥ss.  
Ol. menth. ℥xv.  
Mist. camph. ℥viii. M.

A tablespoonful to be given three times, at half-hour intervals—the dose then to be repeated every two hours, or sooner, if necessary. Other modes of treatment I have found also successful, after the emetic and purgative, such as giving arrow-root and brandy, or carbonate of ammonia and opium, while at the same time an enema of ten grains of acetate of lead, a drachm and a half of lau-

danum, half an ounce of brandy, and three or four ounces of thin arrow-root was thrown up the rectum.

Another system of treatment (still with the same objects in view of allaying pain and purging, producing a warm and profuse perspiration, and stimulating the circulation) will probably startle some members of the profession, yet I have adopted it with the best results, and will again, should unfortunately this disease appear in my regiment. It consisted in the administration of large doses of opium combined with some stimulants, accompanied by long-continued friction of the hands, legs, and abdomen with flannels, either dry or soaked in turpentine. Wet flannels are more hurtful than otherwise, as the moisture left on the skin produces a chill when the rubbing ceases. I will give an extract from a report I made on the epidemic of 1854:—

“It was surprising how few vomited these draughts, and even those whose stomachs rejected the first, were generally able to retain a second. Two to three drachms of tincture of opium were given, with three to four drachms of turpentine, or eight grains of carbonate of ammonia with some camphor water. Among the patients benefited by this mode of treatment, those who were admitted with a warm skin and perceptible pulse, quickly improved, vomiting ceased, diarrhœa became subdued, and cramps disappeared; while some who were brought to hospital cold and pulseless, rallied, were thrown into a profuse warm perspiration; the pulse re-appeared at the wrist, and the features, at first dull and expressionless, became marked with animation and hope. Most of those treated in this manner showed no indication whatever of labouring under the injurious influence of the large doses of opium; for even where the narcotic was repeated in similar or diminished doses, no unusual inclination to sleep was observed. Yet, it must be admitted, that a few cases after restoration to warmth and comfort, fell into a comatose state, in which they sometimes continued for upwards of two days. Whether this is attributable to any specific action of the morbid poison on the brain, or to the exhibition of opium, I will not pretend to say.”

This will by many be considered heroic treatment. In India and China I have repeatedly tried the same treatment, I do not say with invariable success, for I do not pretend to the knowledge of any specific for this disease. In this country I should be inclined, after eliminating the poison or irritant cause, to try the same remedies, in perhaps smaller doses, carefully watching the results. I would point out two ill-effects which may follow this treatment—strangury and consecutive fever; but these will be found very amenable to treatment, such as counter-irritants over the kidneys, diluent drinks, and the use of diuretic and diaphoretic medicines, with properly regulated diet. During the whole progress of the disease, the condition of the brain, lungs, kidneys and liver, must be closely attended to, especially the two last set of organs, as suppression of urine and an entire absence of bile may have to be remedied. In post-mortem examinations which I have made of men who died of this disease, I have often found the lungs either congested or collapsed, the kidneys and liver highly congested, and the stomach and bowels in an apparently healthy condition.

Your space and my time urge me on to a conclusion for the present. I shall, however, be glad to resume the subject, and give, which is all I desire or profess to do, the result of my experience and observation of this disease. Before concluding, however, I would wish to say something more, as especially bearing on the treatment of the last stages of cholera. In the treatment of the stage of collapse, the general principles must not be lost sight of in the hurry and excitement of the moment.

If the physician first sees the patient when he is in a state of collapse or merging to it—with his face shrivelled and anxious; his hands presenting the appearance of those of a washerwoman after a hard day's work; his skin blued and clammy; his pulse thready or imperceptible; his stomach casting up a thin pale fluid; his bowels ejecting the cha-

characteristic "rice-water stools," like thin gruel in appearance (or there may be a total cessation of vomiting and purging), and his body writhing in the agonies of spasms of the abdomen and extremities, or it may be a state of almost death-like quiescence—then he must be quick and energetic in his treatment. The cold clammy damp should be removed from the surface of the body; the limbs should be rubbed upwards either with the dry hand, or flannel soaked in turpentine; blankets should be heaped on the body, and under them the rubbing should be carried on; a mustard emetic should be given, which, even if it does not act, will assist in the great work of restoring the circulation to a more healthy condition. If there is purging a mild aperient should be given, quickly followed by hot brandy and water, brandy and thin arrow-root, or draughts containing ammonia, or turpentine and opium, or any of the numerous remedies which tend to hasten the sluggish circulation, to allay pain, and to produce a warm healthy perspiration; a hot bath is worse than useless, on account of its debilitating effects. If the patient is reduced to that stage when pain, purging, and vomiting have ceased, it seems useless to give either food or eliminative remedies, as the whole alimentary system seems paralyzed. The attention should therefore be directed to the restoration of a healthy perspiration and an increase of the circulation, and this is best obtained by dry friction upwards of the body and limbs with the hand or flannel soaked in turpentine, by heaping blankets over the patient, and by the internal use of hot brandy and water and other stimulants; as soon as the circulation increases in rapidity, and the skin assumes a more healthy appearance, then an attempt may be made to eliminate any poison or offending matter from the system.

In conclusion, I would desire to state that I shall be at all times most willing to render any assistance, professional or otherwise, to any of my brethren, or assist in carrying out any sanitary arrangements in which my services may be of any avail.

### RICHMOND HOSPITAL.

### CLINICAL SURGICAL LECTURES.

By JOHN HAMILTON,

SURGEON TO THE RICHMOND HOSPITAL, AND TO SWIFT'S HOSPITAL FOR LUNATICS.

### LECTURE III.—PHYMOSIS.

If the vascular supply to the prepuce is cut off by a deep phagedenic ulcer at its base, it soon runs into mortification, and more or less of it becomes black and shrivelled and separates, leaving a portion of the prepuce behind it. I have seen the whole of the prepuce so destroyed that in fact complete circumcision was effected. At other times an opening through the prepuce is effected by the ulceration on its inside perforating it through and through, the opening, though contracted, remaining after healing has taken place. I met with a curious case of this. A man was admitted into the Richmond Hospital, October, 1849; he had had several chancres round the orifice of the prepuce which it greatly contracted, and induced phymosis. At the same time he had chancres also within the prepuce at its base, where it is reflected from the corona glandis. By the extreme contraction of the orifice of the prepuce, the matter secreted by these chancres did not get vent, and ulcerated its way out at the base of the prepuce at two places, one a little anterior to the corona, the other a little behind it, where the matter had burrowed. Previously to this he suffered much pain, and the penis was swollen; but after the ulcers had perforated and the matter had got vent he became easy. When he came into hospital the contraction of the orifice of the prepuce was still extreme, and when he passed water it did not get exit readily through it, and therefore gushed out in two streams through the ulcerated holes. I passed a director

from the anterior hole out through the prepuce and divided the intermediate parts. The urine now meeting with no obstruction ceased to come through the posterior opening, which gradually closed. If the chancre is at the side the perforation will be there too; but if the perforation by sloughing is on the dorsum of the prepuce and large, the glans is apt to come through the opening, forming what has been called a hernia glandis and requiring subsequent removal of the pendulous flap. All these cases show the

Fig. 1.

Fig. 2.

necessity of ascertaining the seat of the chancre and of anticipating perforation of the prepuce and subsequent operation and long-continued suffering, by slitting up the prepuce at the proper place.

There is a case in which there is no time to deliberate, out when your decision is of immense importance to the welfare of the patient—I allude to where a phagedenic ulcer under the prepuce not only causes phymosis but opens an artery and gives rise to hæmorrhage. The artery may be one of the dorsal arteries, enlarged by the inflammation and opened by the burrowing phagedena. The bleeding is often excessive, and before assistance comes a large quantity of blood is lost. It sometimes happens when the patient is in bed and asleep without any warning, and he awakes in a pool of blood. You cannot be too quick in slitting up the prepuce and exposing the seat of the hæmorrhage. I could relate many such cases.

I was sent for in a hurry to see a young man who was said to have a violent bleeding from the penis. I found, in truth, that he had lost a very large quantity of blood, and was still bleeding very smartly from under the prepuce, the orifice of which was plugged up with a large clot. He had had a chancre for a fortnight, with inflammatory phymosis, with much pain and tenderness, and profuse thin curdly discharge, and a good deal of fever. He had begun to bleed about an hour before I saw him, and as far as I could judge, had lost about a pint of blood. I at once slit up the prepuce by means of a sharp bistoury probe; with a small ball of bread at the end. I then discovered a large phagedenic ulcer, bigger than a shilling, very deep, and which had burrowed under the fascia of the penis into the corpus cavernosum on the right side, and from which the blood spurted in a jet. After in vain having looked for any distinct vessel by candlelight, I cleaned the ulcer, and filled it up with small pledgets of lint steeped in spirits of turpentine, securing a certain amount of pressure by rolling a couple of strips of lint round this. There was a slight return the following evening, but it was easily restrained. Five days after the bleeding recurred more smartly, so that before I saw him he had lost six or seven ounces of blood. I perceived that the ulcer had burrowed rather higher up under the fascia, so I divided both the skin and fascia for about half an inch. The sore was deep, but no longer phagedenic, the bleeding was free but not spirting. A compress of lint, wet with turpentine, was applied, and there was no further bleeding. His mouth became fully affected by calomel and opium, and the chancre rapidly improved, became florid and granulating, and he was not long in getting quite well, with the loss of a small portion of the glans on the dorsum of the corona.

*Case 2.*—A young man, aged 19, was admitted into No. 1 ward of the Richmond Hospital, February 23, 1863, with rather acute phymosis, with thick purulent discharge of a dirty brownish colour, but not thin or oily. A week before admission he contracted a chancre, and three days after, while carrying a heavy basket of pigs' cheeks, he struck the penis against some iron rails and hurt it severely. He was put to bed, ordered to syringe frequently with cold water, to wash away the discharge, and then to syringe with black-wash: to take two grains of calomel and a quarter of a grain of opium three times a day. 25th: While in the operating-room I was told he was bleeding. I found that the bleeding had commenced about two hours before, and that he had lost a large quantity of blood, there being a good deal about the bed and his shirt, the hair of the pubes and scrotum was clotted with it. A dark clot projected through the end of the prepuce. I at once passed a director under the prepuce on the dorsum as far as it would go, and divided the prepuce through the whole extent. The inside of the prepuce was stuffed with coagula; these were rapidly removed, and bright arterial blood was then seen welling up rapidly from a deep ulcer at the left side of the corona, which had eaten under the skin and fascia of the penis. I stuffed this with small pledgets of lint wet with turpentine, and applied by means of a needle two ligatures to the bleeding corners of the cut prepuce. All bleeding was thus entirely stopped.

March 2nd (six days after): No return of hæmorrhage; mouth sore; he feels better, and there is less inflamma-

tion of the body of the penis, but the flap of the prepuce is purple and dead, so I cut it off. The glans looks soddened and whitish with exudation on it, undermined at its coronal edge by grey phagedenic ulceration; the hole at the left side, whence the hæmorrhage came, is not larger, and the discharge less. Ordered to stop the mercury. I applied nitric acid freely over the surface of the ulcer and covered it with pieces of oiled lint.

22nd (twenty-eighth day): Left the hospital, the whole ulcer nearly healed, a portion of red granular sore alone remaining; a small portion of the glans has been destroyed; he has plumped up, and his present healthy appearance contrasts with his sickly hue on admission.

These cases are acute, but there is a peculiar form of syphilitic ulcer of which I have a greater dread—viz., the chronic creeping phagedena—which, with a pale greyish-yellow shreddy ulcer destroys the part, and has a great tendency to burrow under the skin, destroying the subcutaneous cellular tissue, and, finally, the skin itself. It is rather a painful disease, particularly at night, which is restless, and attended with much constitutional disturbance. I do not know of any good description of this most serious ulcer, and I have not space at present to say more than that it occasionally opens a vessel. The worst case of this kind of hæmorrhage I ever met was from this chronic phagedenic ulcer. One evening, some years since, I was asked to go in all haste to Aston's-quay to see a Scotch gentleman who was said to be very ill. He had had a chancre for seven weeks, four of which he had been attended by the late Dr. Hayden, who had given him mercury to salivation, but without any improvement to the ulcer, which was in a great measure hidden by congenital phymosis. At length, besides the yellow matter which had flowed copiously, blood began to flow, and he had several smart hæmorrhages, for one of which I now saw him. He had lost a great quantity of blood, his shirt saturated with it, as well as the sofa on which he was lying, and there was under him a large clot which stuck to him. He raised himself up when I entered the room, but instantly fell down off the sofa on his head on the floor in a dead faint. There was a clot sticking out of the orifice of the prepuce. He was so timid and so enervated that he could not be brought to let me slit up the prepuce to get at the ulcer, the seat of the hæmorrhage. I was, therefore, obliged to content myself with stuffing the inside of the prepuce with small bits of lint. This effectually restrained the hæmorrhage, and next day, while he was under chloroform, I slit up the prepuce at the under part where I felt the ulcer to be. Half the glans was destroyed by a large, grey, shreddy-looking chancre. Proper applications were made, but it was not till at the end of two months that the chancre was healed.

Chancres round the orifice of the prepuce, even when small and uninfamed, merely by causing thickening of the orifice and by destroying the natural extensibility, induce phymosis. There are usually many of them, for as the sides of the orifice lie in contact inoculation is easy, they have an appearance as of ulcerated fissures, which, when the foreskin is somewhat retracted, open out into distinct oval ulcers. When phymosis arises from this cause it is non-inflammatory, the irritation and redness extend but a short distance from the orifice, but from the deposition round the chancre, this part feels as hard as in indurated chancre.

Now, in such a case, with sores so isolated, you would naturally be tempted to perform circumcision and relieve at the same time the phymosis, cut off the chancres from contaminating the constitution, and perform, as it were, a radical cure of the disease. Petit with these ideas performed this operation one hundred and sixty years ago; but after having tried it in several cases he came to the conclusion that it does not exempt the patient from the constitutional effects of the disease, for in the majority of cases, though he took pains to remove the whole of the diseased part of the prepuce, the patients afterwards came

to him covered with pustules. There is an objection to this operation also that occasionally presents itself—viz., that the incisions become inoculated with the virus of the chancres and become specifically ulcerated. I have seen this several times. You will sometimes find also other ulcers exist within the prepuce, on the sulcus of the corona glandis, or at the side of the frenum, small and masked by the phymosis and constricted orifice. In this case your incisions would infallibly become chancreous. Some years ago a young man of the name of Quilp, 20 years of age, was admitted with phymosis of a month's standing from chancres with induration round the orifice of the prepuce, so constricted that a probe could barely be admitted through the orifice. I performed circumcision, and then for the first time was seen a small chancre round the orifice of the urethra. The incisions at the end of a week became chancreous, but to remove all doubt I inoculated in the thigh and produced a true chancre.

We may conjecture the presence of other chancres within the prepuce, if, when it is drawn as far back as possible and the chancres wiped, yellow matter still oozes out, we may even feel a hardness and tenderness at a particular spot. It is best not to operate in such a case, unless the patient previous to the disease laboured under a natural phymosis, or experienced much difficulty in uncovering the glans.

I usually treat chancres round the orifice of the prepuce and consequent phymosis with strong caustics, so as to produce sloughing of the surface, best accomplished by the application of a saturated solution of the nitrate of copper. After the slough was separated, lint wet with black-wash and rolled up small enough to be put up into the contracted orifice of the prepuce, and then unrolled a little so as to apply itself to the surface of the chancres. If after a few days the chancreous character returns to the sores, it is best to administer mercury to slight salivation, and keep the patient under its influence for about four weeks. The sores are in this way most rapidly healed, and the occurrence of secondary symptoms rendered less likely. After the chancres are some time well, the phymosis will continue till the deposition is absorbed, the hardness removed, and the natural extensibility restored to the orifice of the prepuce.

## Hospital Reports.

### THE LONDON INFIRMARY FOR EPILEPSY AND PARALYSIS.

(Under the care of Dr. ALTHAUS.)

#### ON THE TREATMENT OF EPILEPSY.

In speaking of the treatment of the epileptic attack and the epileptic condition generally, Dr. Althaus remarked that epilepsy was one of those diseases which the majority of medical practitioners believed to be incurable from the first, and that therefore little hesitation was generally felt in forming at once an unfavourable prognosis of such cases. From its violent and formidable symptoms, and the reputed inefficacy of remedies against it, epilepsy was by the ancients believed to be a direct and irrevocable infliction of Providence, and was therefore distinguished by the term "Morbus sacer." Although we no longer spoke of a sacred complaint, yet to this day the idea which it was intended to convey by that name had to a great extent kept its ground amongst the medical profession. He had known many instances where, as soon as the disease had become developed, the dietum had gone forth that the affection was irremediable, and that the patient and his relatives must submit to the inscrutable designs of Providence, and bear the misfortune in a meek and resigned spirit. This he stigmatized as culpable negligence, and said that no progress in medical science would be possible if we were to allow this spirit to prevail,

and shield our ignorance or apathy behind what we might presume to call the designs of Providence. He alluded to the circumstance that "the designs of Providence" was one of the objections most pertinaciously put forward against vaccination in order to illustrate how wrong it would be for us to use such false and irreverent argumentation.

In forming our prognosis we had, in epilepsy, as in all other chronic diseases, first to consider whether there existed any organic lesions, or whether the symptoms depended merely upon disturbances of function and the finer processes of nutrition, without manifest alterations of structure discoverable to our senses. Dr. Althaus went fully into the evidence now accumulated to show that epilepsy was a functional disorder of the brain, and concluded that this fact alone showed the curability of epilepsy, for we possessed remedies by which all the functions of the body and all the finer processes of nutrition could be powerfully influenced and controlled.

Apart from this, which might be put down as a general proposition, there were, however, several special points to be taken into consideration, which had an important bearing on the prognosis of epilepsy. This disease was not to be cured in a few days, or by a single prescription. In most chronic diseases the treatment had to be chronic likewise, and unless both patient and physician persevered in it the result would be most likely disappointing. In fact, it would be unphilosophical to expect a very rapid cure of such diseases, as they were almost always the result of minute morbid changes which had been slowly going on in the affected organs for a considerable time, and which could not be corrected at once by a miracle. Although in the majority of cases the most striking manifestations of the disease—viz., the attacks—might be put down in a comparatively short time, yet the epileptic condition was thereby not immediately eradicated. In order to do this we must cause a thorough change in the nutrition of the brain; and such could only be effected with time. Most of the patients he had cured had taken medicine regularly from six to twelve months consecutively, and the progress of the cure had always been most steady and satisfactory in those amongst them who took the remedies in a proper and business-like manner.

It had often been asserted that confidence in the physician was of the greatest importance for the cure of epilepsy, but Dr. Althaus did not believe that it was of more consequence in this than in other diseases. Epilepsy not being an emotional affection, its progress was not influenced by the mere hope of a cure held out by the physician. In this respect there was the greatest possible difference between epilepsy and hysteria. The latter complaint, with all its symptoms, was powerfully affected by moral emotions, acting on the imagination and the will of the patient; and by the agency of faith, by a happy change in the circumstances of life—nay, by the mere statement of the physician that the case was curable, patients had recovered from severe affections which had lasted for years and resisted every treatment that art had been able to devise. Such was not the case in epilepsy. That formidable disease could not be charmed away by the strongest faith; it could not be improved or cured by a mere feeling of confidence in the skill of the physician. The epileptic constitution was one of such stubborn obstinacy that we must look to such medicines by which we could essentially modify and alter the nutrition of the brain and nervous system as the sheet-anchor in the treatment of the disease.

One of the greatest difficulties Dr. Althaus had had to contend with in the treatment of epilepsy had been the want of devoted and intelligent attendants, ever on the watch for the symptoms preceding an attack. In some instances, indeed, the patient was struck down suddenly without any warning whatever; but in the large majority of cases there were premonitory symptoms which announced the impending attack. It was then that the power of preventive medicine must be brought into play

without loss of time, so that the convulsive tendency might be checked before breaking forth in all its might. Of course, where the patient's bodily and mental health was satisfactory in the intervals between the attacks, so that he was able to take proper care of himself, we would, as a rule, have little difficulty, as most epileptics were anxious to get well. It was different in those cases—and they were by far the most numerous—where the patient was so unwell that he was left to the good offices of those who surrounded him, and there the result of the treatment must in a great measure depend upon their assiduity and intelligence.

The general circumstances of life had a considerable influence on the prognosis of epilepsy. Those whose means allowed them to have everything that was requisite for them had a better chance of getting well than those in straitened circumstances. Poverty, however, was not an absolute impediment to the cure. Most of the out-patients at the infirmary were poor, and yet there were continually striking instances of recovery amongst them. It was, however, different with those who were *very poor*, as due regard to the ordinary rules of hygiene was of the greatest consequence; and where they were neglected from sheer want or necessity the prognosis was certainly far less favourable. As regards sex and age, he had found that women were more easily cured than men, and the young more easily than the old. He thought that the better prognosis for the female sex was entirely due to the circumstance that women were, as a rule, more manageable patients than men, and more inclined to follow strictly the behests of the physician if he had once succeeded in commanding their confidence. Young patients had in almost all diseases better chances of recovery than the aged; yet even great age did, in epilepsy, not absolutely prevent recovery. There was now amongst the out-patients a man, aged 77, who had, in addition to severe epileptic fits, been sorely troubled by gouty pains in his elbows, knees, and feet, and who had now, after a short course of anti-epileptic and anti-arthritis remedies, been quite free from attacks as well as from the gouty pains for a considerable time.

It was generally believed that the resistance to a cure increased with each year, and that the greater the number of attacks which had actually taken place the less was the chance of recovery. Thus Herpin had asserted that, if less than a hundred fits had taken place, the prognosis was favourable; where the number was between 100 and 500 it was doubtful; and where it exceeded 500 it was altogether bad. Dr. Althaus had found that these assertions were incorrect. Epilepsy, even if it had lasted a long time, was for that reason by no means incurable, although generally recent cases might be more rapidly cured than such of long standing. A knowledge of the number of fits which had taken place at the time the case came under treatment did not give us any certain power of foreseeing the probable result. He had notes of a case—which had proved exceedingly stubborn—where only six attacks had occurred altogether at the commencement of the treatment; and he had again met with others which yielded rapidly to the means employed, although thousands of attacks had taken place in the course of years. One patient of this latter kind, who was sent to him from Paris by Dr. Marion Sims, had for about seven years suffered from the disorder; she had had as many as 165 attacks in one week, and no less than 3603 in the year before she came under Dr. Althaus' care. That patient had altogether undergone more than 10,000 attacks; yet, in this case of almost unexampled severity, he succeeded in a single week in reducing the number of attacks from 109 to 6, and the week after that the patient had no more. Two months afterwards a relapse took place, but was as speedily got under, and the patient had now for two years been free from the disease, and been altogether in perfect health. The successful issue of this case—perhaps the most severe on record in the annals of medical science—went far to show that by a careful selection of remedies,

and by a judicious perseverance in their use, favourable results might be obtained even in cases which would at first sight perhaps seem incurable.

## RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

### DR. LYONS'S CLINIQUE.

#### ENGLISH CHOLERA.

THE occasional occurrence at this season of well-marked cases of "English cholera" is familiar to all practitioners. Such cases, however, acquire a special importance at a season when the combined terrene and atmospheric conditions capable of inducing true or "Asiatic cholera" are known to be present or approaching. In the general state of apprehension which prevails under these circumstances, all forms of disease attended with vomiting, purging, and cramps, are apt to be set down as cases of "Cholera," and treated accordingly. This, however, is a practice fraught with danger should an indiscriminate employment of astringents be at once resorted to on the first alarm of diarrhoea.

To treat by astringents a patient in whom purging, vomiting, and cramps result from an effort of Nature to clear the *primæ viæ* of the foul accumulations, the consequence of a surfeit of unwholesome food or ordinary aliment ingested in excessive quantity, is plainly contrary to common sense, as well as to any scientific principles of medication; and yet such a practice is too often had recourse to. That death should occasionally ensue from an attempt, under these circumstances, to lock up the bowels, is not to be wondered at. The majority of such cases yield readily to an opposite plan of treatment, promptly and judiciously employed. The following case forcibly illustrates this position, while, from the suddenness of invasion and severity of the symptoms, it might readily have been taken for, and treated as, a case of "Cholera," and if fatal, would probably have been recorded as such:—

J. K., a fine strong girl, about 20 years of age, unmarried, a general servant, was suddenly seized about four p.m., while ironing clothes, with severe and continuous pains in the bowels, attended with cramps in the legs and smart vomiting and purging, which continued for several hours. She was admitted to the Hardwicke Hospital, where she was assiduously stuped and fomented, and a smart aperient of castor-oil and rhubarb, with twenty-five drops of tincture of opium, was administered. Free evacuation of the bowels was thus produced, and great relief to all the symptoms followed; much soreness in the abdomen and legs continued for a short time, but she was fully convalescent and able to leave hospital next day.

It was ascertained that this girl had eaten a large quantity of peas, probably improperly dressed. The case has perhaps but one point of interest, but that an essential one—the necessity for discrimination before astringents are had recourse to in cases presenting diarrhoea and vomiting. Dr. Lyons is entirely opposed to the incautious use of astringents in cholera periods, and thinks on the whole a moderate dose of castor-oil, with tincture of rhubarb (two drachms of each), and twenty to thirty drops of laudanum, a safer remedy for common use, until medical aid can be procured, than any form of simply astringent medicine.

#### ASIATIC CHOLERA.

J. K., aged 33, not married, temperate, of spare habit, but of vigorous frame, of energetic temperament, in good circumstances, for some years a resident in Australia, usually enjoying good average health, went from his house in Poolbeg-street, Dublin, to Liverpool, on a pleasure excursion, on Saturday, 28th July, 1866. He sojourned with an aunt in good circumstances in the district of

Bootle, but made frequent visits to various parts of Liverpool, and subsequently specially observed upon one street which he passed through as apparently remarkable for much misery and sickness, of nature unknown. There is no evidence that he was in any special manner exposed to the contagion of cholera while in Liverpool, or that his associations, habits, food, or drink, while there, were such as to predispose him to the disease.

J. K., returned to Dublin by the *Iron Duke* steamer on the morning of Tuesday, August 7th. The passage was a very rough one, and though long accustomed to sea voyages on former occasions, he became excessively sick, and vomited freely. Disturbance of the stomach continued even after his return home, and he threw off some tea made for him when he reached his house, and the nausea continued a good part of that day, but no account of any diarrhoea during this period could be elicited. By Wednesday, however, he seemed to have become himself, and it is stated that he was particularly cheerful on Wednesday evening, narrating the results of his observations in Liverpool. He ate fried bacon and eggs for his dinner. Later in the evening he complained of his feet being cold, and took some brandy-and-water in consequence of this and of some rumbling sensation in his bowels. Nothing was thought of these symptoms, however, and nothing further was observed about him by his sister and other friends, who were kind, close, active, and intelligent nurses to him throughout the remainder of his existence. He retired to bed about eleven p.m., and from his own subsequent statement had not occasion to rise till daylight, somewhere between two and three a.m. on Thursday morning, when he found it necessary to rise and go to the privy in a small yard behind the house. Between this period and seven a.m. little or nothing is known of his illness. At seven a.m. he was found by his sister up and dressed, but looking exceedingly ill; vomiting and purging, with cramps in the belly and upper and lower extremities, were now constant. The *egesta per anum* were at first *fæcal*, but soon assumed a greenish watery appearance. He was seen about eight a.m. by a highly intelligent practitioner, Dr. O'Farrell of Dominick-street, who found him pulseless, with the hands and feet cold, vomiting freely, passing large quantities of thin greenish fluid, of very foul odour. A pill containing one grain of opium was at once administered, and all proper means were put in requisition to keep up the temperature by hot fomentations and jars, and a moderate quantity of brandy was administered at intervals.

At nine a.m. he was seen in consultation by Dr. Lyons with Dr. O'Farrell. He was perfectly conscious, able to put out his tongue, and to answer all questions in a strong and firm, though somewhat querulous, tone of voice; the hands and feet were cold; the surface cold and moist, but not blue; the tongue was creamy white; breath still warm; the eyes not sunken, but the pulse at the wrist was completely absent, and the stethoscope placed over the heart elicited exceedingly faint *tic-tac* action at a rate of about 120 per minute. There was neither vomiting nor purging at this period, but cramps in the legs and feet, arms, and hands, and occasionally in the abdomen, were complained of, and the abdomen was soft and somewhat full; the hypogastric region was carefully examined, but not the least evidence of the presence of urine could be obtained, and from first to last no urine was passed or secreted. Little or no thirst was complained of, and great difficulty was all through experienced in getting the patient to drink anything. Tea was the only fluid which he took readily. Active measures were immediately adopted to restore the circulation and maintain the temperature. Besides hot jars, fomentations to the hands, feet, legs, and abdomen were assiduously applied by means of flannels wrung out in hot mustard water, a mustard cataplasm was placed over the heart, and brandy in soda-water was enjoined at frequent intervals with a view to supply fluid and stimulant to the drained and exhausted system. As the abdomen seemed somewhat full, a draught containing half

an ounce of castor-oil, two drachms of tincture of rhu-barb, and forty drops of tincture of opium were directed to be administered, and a second to be given if the first was rejected. The first was thrown off immediately, but the second was retained. He could hardly be got to take stimulants in any form, or, as before remarked, to drink anything but tea. Having been most kindly and assiduously attended in the interval by Dr. O'Farrell, he was again seen at twelve o'clock by Dr. Lyons. Well-marked rice-water evacuations per anum in large quantity, half a gallon perhaps, were now recognizable; vomiting recurred at intervals, but not in large quantity, and principally coloured by the tea which had been taken; the eyes were somewhat sunken; the hands and feet wrinkled with the well-known "washer-woman's hand" appearance of shrivelled and wrinkled skin. The breath was not cold, the voice was still fairly audible, and the patient gave notice of the spasmodic seizures in his limbs or trunk by calling out "cramp, cramp," and indicating the locality, and was quite impatient when the fomentations were applied too hot, calling out "hot, hot." Fresh attempts were made to rouse the flagging powers of life, but with no avail. By three o'clock p.m. he was in well marked and fully developed choleraic collapse; the eyes sunk, face livid, and all but slight traces of consciousness gone; no great amount of blue-ness was anywhere observable; there was constant passage of a fluid evacuation per anum of the appearance and consistency of thin slummary. He died at eight p.m. after an interval of about eighteen hours from the bowels being first affected. All due means of disinfection were at once employed, and the family were advised to remove.

In commenting on this case, Dr. Lyons observes:—

1. This case is noticeable as occurring in an individual exposed for a time to the influence of the terrene and atmospheric conditions, present in a locality new to him, and inducing cholera in others. Dr. Lyons has seen several instances of individuals who, as is presumably the case in this instance, had resisted the cholera influence in the localities in which it prevailed, but where they had become, as it were, inured to the conditions which surrounded them, and successfully resisted a disease which proved fatal when they were exposed to it in a new locality.

2. It is an example of a deadly charge of the cholera poison producing its effects on the whole comparatively slowly, though not less surely.

3. It is further an example of the failure of a special agent like castor-oil to cure the disease by elimination.

Much uncertainty still invests the subject of intestinal lesions, and hardly any class of cases offers to the practising physician greater difficulty of diagnosis, or more elements of doubt and uncertainty, in determining the question of the therapeutic measures to be employed. Perhaps no part of the human machinery is so constantly and so heavily taxed by the caprices, errors, and indulgences of the patient, while, on the other hand, the very remedies indicated by art often bear no little share in producing or continuing morbid action in the intestinal canal.

Amongst the most common of the affections of the large and small intestines, which we meet in daily practice, some are of functional and some of organic nature, differing essentially in pathological character, and yet constantly confounded under the indiscriminating designation of "diarrhoea."

The vague and ill-defined employment of the term "diarrhoea" to indicate almost all forms of intestinal malady attended by flux in the absence of hæmorrhage is productive of much mischief, often leading to carelessness in both diagnosis and practice, with ultimate disappointment to physician as well as patient in no few instances.

A little consideration will satisfy the pathologist that of the causes acting in the production of intestinal flux, the following are the principal:—Atmospheric vicissitudes and other mechanical or chemical influences, acting on the body from without and suppressing or deranging the action of such great emunctory organs as the skin, lungs, kidneys, &c., thus calling on the mucous surface for vicarious

activity of function; excess in quantity, irritative or otherwise unassimilable quality of the ingesta; morbid states of glandular and other organs tributary to the primæ viæ, and leading to the influx into the intestinal canal of secretions altered in quantity, or in physical or chemical quality; derangement of electrical action, or of nerve power consequent on states of congestion, or the contrary, of primary or secondary nerve centres, as the spinal cord, solar and splanchnic plexuses, &c.; morbid conditions of the intestinal tissues, vascular plexuses, glands, &c., of the alimentary canal itself, leading to imperfect or suspended assimilative action.

That in Cholera any special medication directed to the intestinal canal offers the least prospect of success Dr. Lyons wholly disbelieves. He regards it as a disease in which under a preternatural stimulus to the vaso-motor nerves of the intestinal apparatus a *white hæmorrhage* is set up. He holds that the remedy which a scientific induction would indicate is one applicable to the nervous centres, and one, capable either of intensely stimulating them, or of modifying or controlling the profound impression primarily made upon them. To attempt to stop the flux by acting on some part of the intestinal canal seems to him comparable to an attempt to stop the current of electricity through the Atlantic cable by acting on its outer covering. The remedy to be sought must be one to act energetically on the dynamic nervous centres, which preside over intestinal elimination.

### TREATMENT OF CHOLERA IN THE HOSPITALS OF LONDON.

SINCE the beginning of the epidemic which is now prevailing in London there has been nothing either particularly striking or new in the treatment adopted by the physicians of these institutions. A great variety of methods have been put in practice, but unhappily with no more favourable results than on former occasions. The conviction thus forces itself on the minds of some observers, that the variations observed in different epidemics, and in different sets of cases of the same epidemic, are to be ascribed to the varying type and severity of the disease, rather than to any effect from treatment.

The points in common relate chiefly to such subjects as disinfection. At all the hospitals the clothes and bedding, and most of all the excreta of the patients are immediately disinfected. Carbolic acid, chloride of lime, chloride of zinc, indeed all the disinfectants, are in turn resorted to. Calomel, opium, camphor, castor-oil, sulphuric acid, and the thousand-and-one specifics that have been recommended, have all in turn been tried, and under the use of each the mortality is undiminished. Yet every day brings only fresh specifics to hand, and many hospital physicians are overwhelmed with entreaties to try this or that by charitable but credulous people.

#### LONDON HOSPITAL.

AT first Dr. Fraser, who has seen other epidemics, tried five grains of ammoniac sequicarbonas every hour. Enemata of chloride of sodium were also used. Mr. Little injected saline liquids into the veins of several cases, a treatment which had been tried by his father in previous epidemics at this hospital, and from which we had hoped a greater measure of success than has yet been attained. Under Dr. Fraser's care cases have also been treated by castor-oil; others by the inhalation of steam; more recent ones by calomel, a scruple for the first dose, and half a scruple at intervals of two hours afterwards. Dr. Davies first of all gave Stevens' saline treatment a trial. The podophyllin and camphor, and sulphuric acid mixture with small doses of hydrocyanic acid in it. More recently, he has adopted calomel, five grains every two hours.

Dr. Andrew Clark usually orders prolonged warm baths,

and warm enemata. If the stools are feculent, a dose of castor-oil; but patients seldom arrive at the hospital until the evacuations are watery, and the skin blue. Saline lemonade, lead pill, and astringents are also employed. His baths are sometimes medicated with permanganate of potash.

Some observations are being made at this hospital with the thermometer, and other records,—will, no doubt, in due time be published; but so numerous are the cases, that it is quite impossible for full reports to be kept, as will appear from the following table.

Patients of cholera wards up to August 8:—

|                              |     |
|------------------------------|-----|
| Admissions . . . . .         | 450 |
| Recoveries . . . . .         | 131 |
| Deaths . . . . .             | 206 |
| Remain in Hospital . . . . . | 113 |

#### GUYS' HOSPITAL.

THE cases at this hospital have not been numerous. Dr. Barlow has prescribed effervescent mixtures with hydrocyanic acid (2 minims for a dose). Sometimes a small dose of calomel and opium, 1 grain of each.

Dr. Owen Rees has tried the inhalation of nitrous oxide in two cases, but without success. He has also tried the hypodermic injection of quassine.

#### ST. BARTHOLOMEW'S HOSPITAL.

ONLY a few cases have hitherto been admitted at this hospital. The treatment chiefly adopted has been calomel and opium, baths, sinapisms, &c. Beef-tea injections have been freely ordered.

#### BELLE ISLE HOSPITAL SHIP.

UPWARDS of thirty cases have been admitted; carbolic acid has been used here by the stomach as well as in enemata. Some other cases have been treated with four grs. of calomel at intervals of a quarter of an hour. In other cases, the hypodermic use of quinine has been tried. The numbers are at present too small to afford a fair contrast of the mortalities under these several modes of treatment.

#### ON PUERPERAL TETANUS.

DR. W. A. GORDON relates three cases of a rare but very interesting disease, tetanus, following abortion and labour:—

Case 1.—A healthy temperate Irishwoman, mother of four children, had aborted at an early period, eleven days before being seen by Dr. G. She had got about her household duties on the third day. On the eighth day she sat along time at the outside door, her feet resting upon the stone doorstep. Next day she complained of pain in the head, which extended to the jaws and throat. Two days later she complained of painful stiffness of the jaws, extending to the back and throat. Intellect unaffected, pulses natural, lochial discharges quite ceased; no symptom of metritis; next day opisthotonos. Death on the fifteenth day after the abortion. Etherisation increased her distress.

Case 2.—May, 1863. A farmer's wife, mother of five children, aged 40. Dr. G. saw her for hæmorrhage, threatening abortion, and signs of metritis. Thirty-six hours later, stiffness of the jaws, neck, and throat, running into severe spasms. Death on the fifth day. Chloroform left her worse. It transpired that she had been subjected to an operation for the procurement of abortion a few days before Dr. G. saw her.

Case 3.—July, 1863. Mother of three children, aged 35. Dr. G. called on account of flooding. Cold applications, ergot, opium, acetate of lead, and tampon of sponge. Abortion was completed, and she seemed to have recovered. Five days after the abortion tetanus set in, and she died eight days later.—*Amer. Jour. of Med. Sci.*

PROFESSOR CHRISTISON  
ON THE EDINBURGH UNIVERSITY MEDICAL  
SCHOOL.

THE following are extracts from the address of Professor Christison, on occasion of the annual graduation in medicine of the University of Edinburgh, which took place on Wednesday, 1st August:—

The University office, which I am called upon in my turn to fill for this day only, charges the professor who holds it with two duties—to deliver an address to the forthcoming graduates in the morning, and in the evening to entertain hospitably his colleagues. I wish very much that the former task were always as easy and as pleasing as the latter. But it is not so. A graduation speech is never easy, and it may be the reverse of agreeable. Should the speaker feel that he has little or nothing very suitable to say, which happens to be now my case. For, in fact, I have been concerned more or less in forty-five yearly graduation addresses, beginning with the first I heard when myself a candidate; and this is no less than the third time that the post of *Promotor Facultatis* has come round to me in turn among the twelve professors of the Medical Faculty. In this pass, the usual topics of the day seem so stale and worn out that I feel them to be for me forbidden ground. I have already twice told our candidates what they came to college to learn, and what they had to teach themselves on leaving it; twice tried to shape out for them their duties, their conduct, their destinies; twice taught them that the pursuit of medicine as a profession, in spite of all its hardships and crosses, will seldom fail to earn for them a life of substantial happiness. Having thus owned to you the straits I am in, I may shorten this unpromising preface by saying that on looking about me I can find no other subject so suitable or so tempting as one which has often been for some time the matter of my day-dreams, and which can scarcely have altogether escaped your mindfulness also—and this is the constitution and well-being of the medical school of the University. This is a general question, that one may take up in a rambling way, which best falls in with my present mood, and with the composition of my audience; for let me add that the custom of pointing this address to the candidates only is a modern change, and that large account was taken at an earlier time also of those outside the University, who used, as now, to honour us with their presence. Of the classical days of the Medical Faculty—of the days which were held to be classical because the professors conveyed their knowledge to the students in low Latin—a single remnant was long left in the Promotor's address. For several years even after I joined the *Senatus Academicus*, the address, delivered in Latin, set out with the imposing exordium—“*Candidati generosi! Collegæ spectatissimi! Auditores omnigeni!*” and it was shaped accordingly. My omnigenous audience will not take it ill that I remember them in recalling this old almost forgotten landmark, and that I choose a subject which they can all thoroughly understand, and in which very many of them must take an interest not much less than our own.

DIFFERENCE BETWEEN THE SCHOOL AND THE ENGLISH  
UNIVERSITIES.

The framework differed in two fundamental points from that of the far older English universities—in extramural instead of college residence, and professorial instead of tutorial teaching. The relative fitness of these several modes of arriving at the main ends of university training has been often made the subject of controversy, which very lately we have seen renewed in the course of schemes for improving education at the Scottish universities. In judging between them, regard must be had to the precise ends in view, to the genius of the people, and to the means within their reach. Whatever may have been the original design of the English universities, they have long become schools in a great measure for the wealthy only; and they

have long commanded immense resources. College residence and tutorial teaching are possible only for the wealthy and with the aid of wealth. Extramural living and professorial teaching are, on the other hand, the most suitable for opening the doors of a university to all ranks except the humblest of all, for a university so framed needs neither costly domiciles, rich endowments, nor heavy fees. Dr. Monro and his patrons chose the latter way of organising their school, because they had to provide for the education, not of the upper ranks of a wealthy nation, but of the middle classes of a people at that time poor; partly, too, because they had before their eyes the example of the Faculties of Arts and Theology, already flourishing under the same system of instruction at Edinburgh and the other universities of Scotland, and partly no doubt also because they saw that, on the contrary, medicine had never taken firm root under the opposite systems of college residence and tutorial teaching—nor, indeed has it done so to the present day—in the Universities of Oxford or Cambridge. The plan originally adopted has been adhered to ever since.

DEFENCE OF THE SCOTCH SYSTEM.

To the Scottish system of extramural university life the objection has been made of a laxity of discipline favourable to immorality, vice, and insubordination. I deny, however, that any proof has ever been brought forward that, under university rule in Scotland, either the greater or lesser vices of students are worse or more frequent than in the universities of England. As to Scottish insubordination, I deny the charge emphatically from long personal knowledge. It may perhaps be that, as some think, the *perferendum ingenium* of my countrymen inclines them too easily to outbreak—under provocation. But I must give our students the benefit of my testimony, that during the long time I have now taught them I have not witnessed a single act of insubordination in my own class, and that none has ever occurred in another which did not arise from mismanagement on the part of the professor.

PROFESSORS v. TUTORS.

Another objection that has been brought against the university system of the medical schools of Edinburgh and the other Scottish Universities is, that professorial teaching, in place of that by tutors, involved too much lecturing; and that the result is to teach too many things and none thoroughly—a smattering of much, but a sufficiency of nothing. Now, I am quite content that the soundness of this objection be tried by the testimony of facts, apart from all argument. The simple question seems to be—What has been the amount of success of the medical school of this University? I apprehend that there can be no doubt of its success having been most extraordinary. From the time when it was established by the first Monro, in 1720, no material change has taken place in its organisation, except that the Chairs of Botany and *Materia Medica* were separated in 1768; and that twenty-one years earlier, in 1747, the important addition was made of clinical instruction, which, by the way, was nowhere else introduced in Britain till nearly a century afterwards. From 1768 to 1825 there were only six professorships in the Medical Faculty, which now consists of twice that number. After 1825 other important changes, which will be presently adverted to, were made in the constitution of the Faculty of the University and in the instruction given by it. But till then no such alterations were made as could affect the scope and plan of teaching.

THE SUCCESS OF THE SCHOOL.

What, then, was the success of the school? During a period of fully one hundred years the concurrence of students increased steadily, till it reached, in 1823, the number of 900. After that the number fell off greatly, for reasons to be given afterwards. The medical graduates, of whom there was only one in 1726, and not another till 1730, rose to 12 in 1750, 22 in 1775, 50 in 1800, and 120 in 1820. They came from all parts of the British dominions,

as well as from some foreign countries. In 1792 the list was made up of almost equal numbers from Scotland, England, Ireland, and the United States, with a less proportion from the West Indies. A census, extending over nearly one hundred years, shows that the attraction to the University has fallen off only from those countries which, in the progress of time, have been supplied with universities of their own, where instruction may be had on the same footing as here at less cost, or without a far journey; and that, as fast as a new source of supply has arisen, the current thence has flowed greatly to the University of Edinburgh. On examining, firstly, the list of graduates for twenty-five years, ending with 1800, during which period this medical school, taught by Cullen, Black, John Hope, James Gregory, and the second Monro, was probably at its greatest height of fame; secondly, the list for ten years, ending with 1819, but adding also, for equality of numbers, about one-half of the graduates in 1820; and thirdly, those for the last eleven years, ending with 1865, we obtain the numbers for the three periods of 800, 800, and 807. Those from Scotland were successively 179, 319, and 405; those from England were 217, 177, and 232—showing no falling off in attraction in that part of the Kingdom; from Ireland the numbers, at first greater than from either England or Scotland, were 237, 236, and 28—no material decrease having taken place till after the foundation of the Colleges of Queen's University in Ireland—since which time, indeed, there has been a prodigious descent. In the earliest of the three periods the United States supplied 78 graduates. But the foundation of excellent universities in several of the States kept many afterwards at home, and the unhappy war in 1812 turned the American tide of fashion and students to Paris; and consequently in the middle period the American graduates fell to ten, and in the last to three only. The decadence of the West Indies, whence came no fewer than 61 graduates in the first period, reduced the number to 31 in the second, and to 17 in that just ended. Switzerland and Portugal sent us 14 in the first, and 15 in the second, but none at all in the third period—for reasons not far out of sight. On the other hand, British America, India, the Cape, Mauritius, and Australia, which in the first period supplied not a single graduate, have sent, as they have successively come under the sway of Britain, 18 in the second period, and 98 in the last of all. The concourse of medical students to the University has not continued so steady as the demand for its medical degree. Superficial or jealous observers ascribe this incongruity to falling-off in the quality of instruction, or to laxity of examination. As for the latter notion, I know well as a professor that the Faculty examinations are now not more lax than formerly, but quite the reverse, and I have no doubt you are all ready to endorse that statement. Of the relative quality of the instruction now given it does not become me to pronounce judgment. But impartial inquiry refers the apparent anomaly of more graduates among fewer students to a cause very different from a falling-off in the value of the instruction to be obtained—viz., that while the celebrity of the Edinburgh medical degree has continued without abatement, the facilities for obtaining it without an education exclusively at the University have been greatly increased. During fifty years, from 1775 to 1825, when the medical classes were the most populous, no education was recognized as qualifying for degrees except what was got at a university. It is true that this education might be got at any university, and without attendance in Edinburgh at all; but university attendance could be had by intending graduates scarcely anywhere else than in Scotland. America long had no medical schools of note of her own. Foreign wars for the most part closed the schools of the Continent equally against ourselves and to certain other nations friendly to Britain. Throughout England, medicine was taught nowhere in a university. In Ireland it could not be studied in a university without the costliness of college residence and submission to terms unpalatable, and to many insuperable.

But Edinburgh, blessed with the ablest teachers, also offered cheap living, and no condition on the part of the student save due capacity and diligence. Thus many circumstances, intrinsic and external, conspired to favour the success of the first great medical school established in Britain for her people, her dependencies, and her offshoots.

#### FITNESS OF THE UNIVERSITY SYSTEM.

Let me now turn back to the argument which has led me into this historical interlude. We see evidence of the fitness of the system of medical education pursued at the University in the continuing demand for its medical degrees, and the populousness of its medical school. Proof to the same effect may be seen also in the fact that every university medical school that has been lately erected as a rival was established and often avowedly, upon it as a model. And further proof may be seen in the circumstance that, since at least the beginning of the present century, Edinburgh graduates have held a prominent place in every branch of private and public professional life in this country. In the public service we find that before the recent appointment of the present head of the Army Medical Department, his predecessors for almost half a century were either Edinburgh graduates, or, at least, Scottish graduates similarly trained; that for the same period an Edinburgh graduate has filled the parallel office in the navy; and that in India the heads of the medical service and other prominent members of it have also been chiefly graduates of Edinburgh. Turning to civil life, we see that for more than fifty years there has never been a time without several of our predecessors being at or near the head of medical practice in London; in almost every considerable provincial city and town of England the leading physician has long been one who obtained his education and professional title here; and wherever a wandering Briton turns his steps throughout our distant colonies, he will seldom fail to encounter at the top of his profession an Edinburgh doctor of medicine. After all that has now been said, and what you, indeed, yourselves know from your own observation, it will surprise you to be told that of late a party have arisen, comprising men of great weight in medical politics, who deny the fitness and superiority of professorial tuition for teaching the profession of medicine; and cry up the advantages of tutorial instruction—that is, by apprenticeship and other similar methods.

#### NECESSITY FOR MORE FUNDS.

I take this public opportunity of making known the financial condition of the University, in order that all persons who take a sincere interest in it, and especially those whose interest it is to share that interest, may know their duty. Public spirit has been so far aroused, that there is a prospect of sufficient endowments ere long from private munificence for maintaining scholarships and bursaries. But, strange to say, for a land whose natives claim for themselves a special share of patriotism and nationality, the munificence of Mr. Muir is the only example, for a very long time, that professorships also require to be maintained on a footing of greater liberality. And as for the general wants of the University, I have already said enough of the inadequacy of the means of supplying them, even since the late partial relief which has been granted. Among others, I call especially on the citizens of Edinburgh to consider well their position and ours. It is a common saying on public occasions here that late changes, transferring much of the former glory and means of our city to the metropolis, have left only three great supports of our fame and prosperity—the Courts of Law, the University, and the romantic beauty of our town. Now, I warn my fellow-citizens that one of these supports is in jeopardy. Formidable rivalry has arisen on all sides around the University—in London, in Ireland, in Glasgow. The contest cannot be supported without the sinews of war. These are got, whenever wanted, for London, for Ireland, for Glasgow. The other day it was

intimated in Glasgow that £100,000 was required to supplement the building fund for the new college there; and at the same time it was made known that £50,000 had been subscribed by her public-spirited citizens without descending lower than subscriptions of a thousand pounds. Will the citizens of Edinburgh consent to lose the race in this rivalry, and to stand the consequences? I do not believe it. They may say, tell us specifically what is most wanted. Well, then, for erecting new halls for teaching anatomy and chemistry, in the new street which we are presently to see, under the auspices and enterprise of Lord Provost Chambers, to the north of the College, a sum of £15,000 is required. Unless this be done, Edinburgh must be content with becoming a very second-rate place as an anatomical and a chemical school; and I presume I need not tell the citizens what will be the consequence of that. I could add a great deal upon this head. But the present is not the fit time or place. Besides, I have already detained you too long. I believe my strict duty on the present occasion was to administer to you good advice on your approaching outset in professional life. But, in the first place, I think this unnecessary, because you will get excellent advice from others in all circumstances arising which may require it, or from your own conscience and experience; and, secondly, I have never yet been assured that your predecessors, on whom, on two previous occasions of the like kind, I did bestow many good advices, have been much the better for them. Allow me, then, to offer you instead the sincere good wishes of our Vice-Chancellor and Senatus, and also my own, and our hopes and confidence that you will all, in due time, arrive at that professional position which your assiduity and conduct as students, and your university training qualify and entitle you to attain.

## Reviews.

**CHEMICAL ADDENDA.** By B. W. GIBSON, B.Sc., F.C.S. London: James H. Dutton, 1, Wine-office-court, Fleet-street, E.C.

As the title page informs us, this little pamphlet is intended as a brief exposition of the salient features of modern chemistry, and is designed as an appendix to the elementary text-books on the science. In his preface Mr. Gibson says, "That his special object is to present succinctly to the student's consideration those changes in theory, notation, and nomenclature which have lately been made in modern chemistry." How the author can condense the whole of these changes—which have lately been made—into a book of twenty-three small pages, is at first sight a seeming impossibility, but a careful perusal shows the matter to have been arranged in a systematic and complete manner, although perhaps a little phonographically. Thus in some places (*e.g.*, when treating of "molecules and atoms contrasted,") we would have wished the author to have been a little more diffuse.

At page 21 Mr. Gibson introduces a table from which the different notations can be contrasted at a glance. The author winds up with a few paragraphs upon decimal and metric tables.

Now that the new notation is about to be introduced into the British Pharmacopœia, we heartily recommend our medical friends to get this little *brochure*, as we know of no work so suited to gain an insight into the modern theories of chemistry which have been promulgated through the works of Frankland, Gerhardt, Hofman, Williamson, and others. C.R.C.T.

**THE SOCIAL SCIENCE REVIEW.** August 1, 1866.

THERE are six papers in this number, and four of them concern our profession. 1, is on the Fallacies of Vital Statistics, and is continued from page 447 of vol. v.; 3, is a good

paper on Epidemics, by William Blower, M.R.C.S.; 4, is an essay or a lengthened abstract of a paper read before the Statistical Society of London, in January of the present year, by T. A. Welton, on the Social Condition of France. It was published *in extenso* in the Society's journal for June. 6, is a curious paper on the Vitality of the Jewish Race in Europe, by M. Michel Levy. We recommend this paper, and that on Epidemics, to the perusal of our readers, who will find much that is useful and interesting in the others also.

**THIRTY-SIXTH ANNUAL REPORT OF THE BELFAST DISTRICT HOSPITAL FOR THE INSANE.** Belfast. 1866.

OF all the reports of Hospitals for the Insane, we know of none more satisfactory to the profession and the public than that annually written at Belfast by Dr. Robert Stewart, the Resident Physician, Superintendent. It leaves little or nothing to be desired, so far as obtaining information is concerned, and it may be regarded as a model for clearness of arrangement and tabular statistics.

We congratulate Dr. Stewart on his reaching the thirtieth year of his connexion with the Belfast Asylum, and we hope the Governors of that Institution may long continue to avail themselves of the services of so useful a public servant.

**THE NEW YORK MEDICAL JOURNAL.** June, 1866.

THIS number contains (*inter alia*) a Historical and Biographical Notice of Cosmo Viardel, by Dr. Geo. T. Elliot, jun., and an account of the History, Etiology, Pathology, Prophylaxis and Treatment of Cholera, by Dr. C. C. Terry of New York. It has a lengthened Quarterly Report on *Materia Medica*, which, like most works on that subject coming from our transatlantic cousins, is full of interest and value. It notices Dr. Duncan's treatment of Acute Rheumatism by Permanganate of Potash, as given in this journal for May 16, 1866. This journal is well printed, and on good paper.

**THE EDINBURGH MEDICAL JOURNAL.** August.

THERE are five original communications in this number—1. Dr. Karell of St. Petersburg, on the Milk Cure; 2. Dr. Warburton Begbie and Dr. W. R. Sanders on two cases of Aphasia and Right Hemiplegia, with Dissections; 3. Dr. Henderson of Helensburgh, on a case of Air found in the Chambers of the Heart; 4. Dr. Ketchen of Forfar, on Diphtheria; and 5. Dr. Rutherford Haldane on a case of Cancer of the Lumbar Glands simulating Abdominal Aneurism.

There are also Obituary Notices of Dr. David Craigie and Mr. Toynece. This number is quite equal to its predecessors.

**THE DUBLIN QUARTERLY JOURNAL OF MEDICAL SCIENCE.** August, 1866.

WE consider the present number a very good one. It contains original communications as follows:—

Dr. R. McDonnell—On the operation of Trephining in cases of Fracture of the Spine.

Dr. Paton of Toronto—On the Action of the Heart.

Dr. Compton of Corpus Christi College, Cambridge, and of Trinity College, Dublin—On Temperature in Acute Diseases.

Dr. Kidd of London—on the Medical uses of Chloroform Inhalation.

Dr. Hayden—On Diphtheria, and Dr. McCormac on Strangulated Inguinal Hernia.

There are eight reviews of greater or less length, one is an essay, entitled "Works on Cholera;" and the Proceedings of the Dublin and Cork Medical Societies occupy their due places.

This number has numerous illustrations, and is much

larger than the ordinary size of the *Dublin Quarterly*, in consequence of its containing a long memoir and copper-plate engraving of Sir Patrick Dunn, M.D., from the pen of Dr. Belcher, who contributed a memoir of Dr. Stearne to the same journal about a year ago. As we understand that this memoir is about to be published in a separate form, at the expense of the King and Queen's College of Physicians, we need not further refer to it at present.

THE TECHNOLOGIST, A RECORD OF SCIENCE.—With the August number this valuable monthly journal enters on its seventh year and commences a new series. It is improved in appearance and in the tone of its articles, and the conductors promise, if well supported, to increase its size sufficiently to introduce reviews and abstracts of the societies, in addition to its usual contents. We may draw the attention of our readers to the articles on the Atlantic cable and on the needle-gun in this number. Specially interesting to the profession, there is also a sketch of the laryngoscope, and amongst the obituary notices an account of the late Mr. Toynbee. The commencement of the new series offers an excellent opportunity to commence subscribing to this useful monthly.

## London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 15, 1866.

### CHOLERA IN LONDON.

THE progress of cholera is naturally the theme of the most engrossing interest at the present moment to the Medical profession, while to the general public the daily accounts of the ravages committed by the disease form the subject of very natural alarm and apprehension. The last weekly return of the Registrar-General shows an increase in the number of deaths from cholera over the return of last week; but although several sporadic cases have occurred in several districts, the chief virulence of the epidemic has still manifested itself in the eastern suburbs, where it still continues to prevail.

A very remarkable instance was recorded a few days ago, in which it appeared as if the patient had swallowed or inhaled a concentrated dose of the cholera poison, for he was seen to stagger and fall down in the streets in the East-end of London, and before he could be conveyed to the London Hospital he had ceased to exist. The post-mortem examination proved that the disease of which the man died was cholera, although from the suddenness of the seizure, it was at first supposed to be apoplexy, even by the Medical Officers of the Hospital. Another instance of sudden death in this disease, although under totally different circumstances, occurred on board the *Belle Isle*, the hospital ship moored in the Thames off Greenwich, a few days ago. The patient was convalescent from cholera, and was on the point of being discharged cured, when he was suddenly seized with symptoms resembling paralysis and died; and on a post-mortem examination congestion of the cerebral vessels was discovered, together with effusion of blood in the cranial cavity.

With regard to the invasion of the disease in the

present summer in the metropolitan districts, it cannot, we think, be fairly attributed to any introduction from foreign ports. This opinion we expressed last week, and it has rather been strengthened than otherwise since that time. Although a vigilant watch is kept upon the cases admitted into the *Dreadnought* Hospital Ship, which, as is well known, receives any male patients of the maritime calling who may happen to be taken ill in the vicinity, no case has yet occurred in which it could be said that the sailor had brought the disease from an infected port; on the contrary, the cases have been principally brought from the houses situated along the banks of the river, from some of the docks, from the barges plying from town to town, and from colliers and other vessels sailing on the Thames. In the case of the latter the most careful investigation has failed to show that the disease was brought from any infected port, and indeed at the time of our writing the number of seaports infected with cholera is very small.

The Medical profession is at present industriously and laboriously engaged in endeavouring to detect the laws which govern the spread of the epidemic, and post-mortem examinations are assiduously made with a view of unravelling, if possible, the pathology of the disease. Unfortunately, little of a definite nature has yet been established, and the conclusions hitherto drawn have been rather negative than positive. It is perhaps almost puerile to observe that it is above all things necessary to check the preliminary diarrhoea, but the observation is not uncalled for when we find a practice advocated in some quarters of encouraging the discharges from the bowels instead of repressing them. It is also to be observed that when the serious symptoms have set in the more promptly medical treatment is sought for the better, and it has appeared to us that many cases have been restored by speedy removal to an hospital and assiduous medical care, which might otherwise have succumbed to the malady.

The local boards, to whom, by our British institutions, the superintendence of our sanitary measures is unfortunately intrusted, have at last begun to bestir themselves in the improvement of the condition of some populous districts, but in the eastern part of the London suburbs the overwhelming violence of the outbreak has almost paralyzed the authorities. There is, undoubtedly, something to be said as to the inequality with which a visitation of disease like the present falls upon the poorer as compared with the richer and less populous localities, and it is to be regretted that the richer classes of society are not compelled to contribute much more largely than they do at present to supply the wants of their less prosperous neighbours. It is true that subscriptions to a very considerable amount have been received by local committees and duly acknowledged in the newspapers, but these subscriptions form but an insignificant fraction of the incomes of most of the subscribers, and are quite inadequate to the necessity.

## HOSPITAL NURSING IN DUBLIN.

THE 1st of August instituted a new era in the history of the Dublin Hospitals. The want of properly trained nurses, both for hospitals and for private individuals, had long been felt in this city, so much so that some charitable persons, with the ARCHBISHOP of DUBLIN and Mrs. TRENCH at their head, have had it for some time in contemplation to establish a system resembling some of those which have been found to work so well in London, where now the hospital nursing is largely conducted by a staff of well-trained nurses and probationers, managed by some society in connexion with the institution. We have frequently discussed this subject of late, and we have given full information about this new institution, so that there is no occasion to go over the ground again; but it may be recollected that when the subject was first mooted the Governors of Steevens' Hospital generously gave up one ward for the purpose of seeing how the system would work, on the distinct understanding that all sectarian principles were to be excluded from consideration. The matter was referred by the Board to the Medical Officers for report, but the latter, in the absence of more accurate information as to minor details, confined themselves to reporting that the then present system of hospital nursing required amelioration. We have been informed that—

"The lady superintendent Miss Beatty, made her first appearance in the Male Accident Ward of the hospital on Thursday morning, attended by her head nurse and two probationers; they set to work and in a very short time a complete new face was put on matters. There are twenty-eight beds in the ward, and these are constantly filled with every variety of accident and surgical disease, so that the labour in such a ward is immense; before attending to their surgical wants cleanliness was to be considered, and here a good deal of prejudice had to be overcome; some actually rebelled against having their faces and hands washed; others insisted on refusing the sheets, and lying in blankets; while a sturdy few objected to having their morning smoke in bed discontinued; the razor and the scissors were put into requisition, and before noon a complete metamorphosis had taken place. It is refreshing to see the unostentatious quiet way in which everything was done; no hurry as might have been expected from beginners; any commands given by the surgeons were accurately and immediately attended to; in fact, everything showed that the system was under judicious management. Although little more than a week has passed since its commencement a visible and real change for the better has taken place; it was at once apparent that the faults under the old *regime* were to be attributed rather to ignorance and want of direction than to carelessness.

"The lady superintendent was herself trained at Netley, where the surgical dressing is almost wholly effected by nurses themselves; there they learn to bandage, strap, &c., and perform many other operations which are effected by pupils in a clinical hospital. Hence under her management women could be trained to a higher class of efficiency than is to be generally met with in either public or private nurses; but in a clinical hospital where the pupils require to be taught, it would not be desirable to allow the training of nurses to encroach on those cases which must be looked on as the professional property of the former. A probationer has to serve twelve months, but Miss Beatty, for the present, hopes to have some few ready in about five months. It will be a real blessing both to a medical

man and to his patient to have at their disposal a person properly trained, and on whom reliance can be placed.

"The house, 152, James's-street, has been taken and fitted-up for the probationers; they sleep and get their meals there, and it is to this place that applications should be made for nurses when the time comes round that a sufficient number have been trained to commence private nursing.

"The support of such an institution is a subject which comes home to all of us, as we do not know the moment when we may require the services of a good nurse ourselves. The amount required will not be much as it is hoped that the society will be mainly self-supporting."

We are glad to find that this system has been inaugurated at Steevens's Hospital, which from the account given above, seems to have very much wanted it. Not long ago, and before any attempt was made to set up this system in Steevens's Hospital it was attempted to be introduced, at the instance of a Medical Governor, into Sir P. Dun's, and only failed because in the opinion of the majority of the Board, there was not at that time sufficient accommodation for a lady superintendent to reside in the house, and her position, as distinct from that of the matron, could not be clearly defined. This nursing system on an "unsectarian basis" looks very well; but in London it is found that the Sisterhood plan, such as that at King's College Hospital, works much better. This latter cannot perhaps be had here just now; but in any case, according to the old adage, "half a loaf is better than no bread."

## NOTES OF LONDON PRACTICE.

THE *Saturday Review* has been going over the evidence of Dr. Acland and Sir B. Brodie, as to what mischief water once charged with sewage matter may do in places like London, and it fears we have now cholera from the sewage of Oxford. However unsound decisions have been as to rinderpest being small-pox, or as to cholera or cubic feet for wards in workhouses and infirmaries, the chiefs of the agitation are now in a rage, whether with Dr. Todd or Dr. Edward Smith. 600 feet are sufficient, or rather 1200 with various sphygmographists, newspaper amateurs, annotationists, &c. Mr. Gathorne Hardy and the Government have taken till November to decide about it, as the whole thing hitherto has been *ex parte* or one-sided. Meanwhile a very severe endemic of cholera rages at the East End of London, due in some large degree to the insufficient out-door treatment of the sick poor, deficient house-to-house visitation, and an idea rather of a mischievous kind amongst the poor that this form of cholera is highly contagious.

Dr. Smith considers that no ward is to be occupied night and day which does not provide a floor space of 54 to 60 feet, a height of 10 to 12, with 6 feet across the bed. (1000 cubic feet is an area of 80 square feet to each bed, the present average of workhouses is only 50). Military and civil hospital authorities are quoted for and against the new measurements; a parliament commission is asked to decide whether six or twelve or eight hundred cubic feet would be the statutable law against all those ills to which workhouse flesh is heir. As might be supposed the debate is pitifully one-sided; cholera and small-pox threatening all the parishes of London. Earl Shaftesbury

believes that the workhouses will never be what they ought to be till there are medical visitors to superintend the wards, and general medical charities. Cholera from the sewage of Oxford is a long way off, but poor-law guardians and vestries helps its spread, neglecting local measures in London.

The condition of the East End of London just now is, in fact, quite terrible to think of; the water at Limehouse described as black as ink and in a state of putrid fermentation, the sewers in many places opened up (at the wrong time) from the *nimia diligentia* of the vestries!

Of matters medical of less note during the week, perhaps we may mention the fact, that for fifty vacancies for assistant-surgeons for India, only thirty-six candidates presented themselves here recently, due, it seems, to the entire innocence of these appointments, in which the "third years' men" are brought up in the London schools, their normal position rather being, in place of £500 a year, assistantships at £30 a year to some half-educated chemist—due, in some measure, too, to the deficient pay and pension in this service compared to the regular army, though on this latter part we believe too many errors are encouraged, and the subject has never been described exactly as it is.

An interesting but sad return has been made at the Brompton Hospital as to twenty patients sent last winter to Madeira; the return is not at all encouraging, two out of twenty returned improved, seven were slightly improved, four were not so well, and one died; in twelve cases the phthisical symptoms remained stationary, in five they advanced!

Of the treatment of cholera not much that is new can be stated, the castor-oil plan and ice-bags have gone to that limbo of annotationists where vaccination for cattle plague, it is believed, will ever remain. A masterly account of transfusion in cholera occurs in an old book, "Mackintosh's Practice," and a few cases have been treated (as these thus first described), and with good results; of other treatment small doses of calomel appear best, the chief benefit arising, however, from stopping the diarrhoea early.

The ceremony of opening the new hospital for paralytic and epileptic patients in Bloomsbury, one day last week, was not without interest. When closed a year ago there were forty beds occupied, and now it is enlarged with 1200 out-patients. It is not necessary to indite anything of the special architecture, but a new gymnasium and an electric-room (like that of Guy's) struck us as very valuable. This hospital was due to the indomitable energy of Dr. Brown-Séquard, whose lectures and clinique we have always attended as a duty, and a suggestive pilgrimage of much pleasure, to the shady and smoke-coloured glades of Queen's-square.

The Bishop of Oxford delivered one of his charming and manly addresses. The hospital was commenced when there was in London a blind rage got up against all specialties, and yet the poor epileptics were not received into the larger hospitals. Epilepsy required separate study, and specific *treatment in its various stages*. It has struck men, said the Bishop, of the greatest intellectual powers, Napoleon I., Julius Cæsar, and even the great Duke of Wellington. It was in 1856, just ten years ago, a great physiologist (Dr. Séquard) had sounded the keynote of the cure of epilepsy. An attempt, not unsuccessful, was made in the leading medical journal to put him

down, and not till 1858 was he heard of, when his lectures at St. Bartholomew's first appeared (in the *Medical Circular*), and in the next year in the columns of his old adversary, where Marshall Hall checked the new extravaganza. We had only now to look around and see what the hospital had grown to, what epilepsy (from the *opprobrium medicorum* of the hospitals in males and females, like ovariectomy, vesico-vaginal fistulæ, &c.) had become. The lectures (first in the present journal) had been reprinted as new in other journals. Still much good would arise, and if any further inducement to assist in the good work were necessary, said the Bishop, with his usual solemnity, he would remind them that the great Saviour when on earth had obviously applied the healing art or power to the epileptics.

[The London Editor does not hold himself responsible for the opinions expressed in the above notes.]

## Correspondence.

### THE LATE MR. TOYNBEE AND DR. BISHOP'S APPARATUS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your journal of this day, under the head of "Contributions from your London Correspondent," you have referred to my notice of the death of Mr. Toynbee, and to the use of my apparatus for applying vapour and spray to the cavity of the tympanum, adding that Mr. Toynbee had not much faith in our ability to reach the middle ear in this manner. You will excuse my writing to correct this error.

There was a time, probably, when these observations might have been correct, but if so, increased experience caused this distinguished aural surgeon to change his views, in proof which I refer you to a short discussion which took place at the meeting of the Royal Medico-Chirurgical Society on the 6th of February, 1866. Dr. Weber of Berlin, on this occasion, exhibited specimens, proving the possibility of injecting fluids into the tympanic cavity. Mr. Toynbee, in commenting on this practice, so far from *doubting* the possibility of accomplishing the object in view, said there was no doubt whatever on this point, but warned the profession as to the *danger of such a proceeding*. This opinion I am sure he would have abandoned had he seen how safely and successfully it can be *done* by myself and others.—I am, Sir, your obedient servant,

EDWARD BISHOP, M.D., &c.,  
Surgeon to the Metropolitan Ear Infirmary, London.

31, Sackville-street, London, W., Aug. 1, 1866.

### THE LATE DR. WARDER'S ALLEGED MURDER AND SUICIDE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I consider your remarks (see *MEDICAL PRESS*, July 27,) on Dr. Alfred Warder's case of very great moment. Here is a member of the medical profession, without satisfactory indirect, and certainly with no clear direct evidence, set down as a murderer and a suicide. It is quite monstrous that such dire conclusions should, on such single grounds as those set forth, be assumed. There are misery and wickedness and lunacy enough abroad, without adding, by suppositious instances, to the list. I say the guilt alleged was *not* brought home by evidence on which a jury would convict to Dr. Warder, and therefore it is that we should be chary to condemn. In the eye of the law, and in the eye of reason too, a man must be assumed to be innocent till he shall be convicted. Dr. Warder was not convicted, whether during his life or after his lamentable decease. I hold,

therefore, that we are called upon to suspend our judgment, and to ask for a reversal of the attainder to which it seems Dr. Warder's property has been subjected. I again beg to express my warm concurrence in everything you have said, your closing sentence excepted, which, I submit, were better left unsaid.—I am, Sir, your obedient servant,

HENRY MACCORMAC.

Belfast, August 3, 1866.

#### MR. COLLIS'S LATE LECTURE ON STRANGULATED HERNIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I wish to correct an error in the history of a case of strangulated hernia, reported by me in the July number of the MEDICAL PRESS. The report is as I received it from the resident pupil, who thought that the case had been under Dr. Moore's care, as he sent it into hospital, the fact being that Dr. Moore had never seen the case until shortly before, and at once sent the woman into the hospital. The following is the history, as given me by Dr. Moore.—Believe me yours truly,

M. H. COLLIS.

#### STRANGULATED FEMORAL HERNIA, OPERATED ON BY MR. COLLIS, JULY 18, 1866.

Ann Baker, æt. 50, or more, not married, was admitted into hospital on the 1st May, with a strangulated femoral hernia on the right side. The patient stated that on the 28th April, when carrying a bundle of clothes on her back, she suddenly got a pain in her bowels; this became very violent, and on her return home she was obliged to go to bed; vomiting came on soon after. She had no previous rupture, and first noticed the swelling on that night. Dr. C. F. Moore of Peter-street Dispensary was sent for; he ordered her a dose of castor-oil, which she vomited. She had repeated attacks of vomiting on the 29th and 30th ult., but none on the day she was admitted. Mr. Moore made efforts to reduce the hernia at different times, but finding it impossible, he had her removed to hospital. Mr. Collis used a reasonable amount of force in trying to reduce the tumour, but finding the stricture very tight, he at once decided on operating, which was done about half an hour after the patient was admitted.

"1st May, 1866. Dr. C. F. Moore was called to see Baker (Ann), æt. 60, having been informed that she had been under treatment, and was taking pills of opium and calomel every four hours for peritoneal inflammation for some days. Turpentine stupes had been also used; she had moved to her present dwelling fourteen days before.

"During Dr. Moore's visit stercoraceous vomiting occurred, which, with the state of the patient, induced him to interrogate her sister very strictly, who persistently affirmed that no tumour of any kind existed in her sister's case, nor did she or the patient allude to any exertion and subsequent pain. However, Dr. Moore, on personal investigation, discovered the rupture; which, on examination, AND ONE ATTEMPT, WITH A JUDICIOUS AMOUNT OF FORCE at reduction, he determined was only to be relieved by operation, and he then with much difficulty induced the patient to enter the Meath Hospital within about an hour from the time he first saw the case, in order to undergo the same."

#### APOTHECARY QUALIFICATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Please let me know through your next paper, if possible, can an M.D. and L.R.C.S.I., on giving sufficient proof that he has been two years apprenticed to a qualified apothecary, practising with open shop in Ireland, and also one year and a half mixing and compounding medicines in the dispensaries of a Poor-law Union, and also attending with the Medical Officer of same dispensaries the out-door practice of the parish, be admitted to the License of the Apothecaries' Hall, Dublin, on passing the prescribed Examination; or, in other words, will the two years' apprenticeship, and the year and six months spent in attending the dispensaries, be taken instead of the three years' apprenticeship required

by the Apothecaries' Hall? Trusting you will reply at your earliest convenience, I am, Sir,

A SUBSCRIBER AND CONSTANT READER.

August 7, 1866.

[We believe he can; but he had better apply to the Secretary, Dr. Leet.—Ed.]

#### MR. RUMSEY ON INSPECTION OF EXAMINATIONS AND THE MEDICAL COUNCIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I do not question the propriety of your publishing my letter to the Branch Council for England respecting the Visitations of Examinations, although it must have come indirectly into your possession; nor have I any reason to complain of your general treatment of the subject. But I trust to your candour to insert the following brief remarks in your next number.

In the first place, I do not think it quite fair to my colleagues on the Branch Council, to intimate that they "kept back" my reasons for not acting with them in this matter. The minutes of Council meetings *never* contain the reasons—whether oral or written—of members, for or against any measure, and there was no sufficient ground for making an exception to the general rule in this instance. Although the letter was not intended for publication, I am not at all sorry that your readers should have been informed that a difference of opinion on this subject exists in the Council, and that the minority have something to say for themselves.

Then, again, in reply to your editorial comments, I beg to observe that your first ground of objection does not apply to my proposal. On referring to it, you will see that the suggested "Examining Board for the Civil Medical Service" was not intended to supersede in any way the established licensing bodies, or to "act alone" in testing the qualifications of medical officers. I expressly guarded my recommendation against any such inference, so that it is not touched by your criticism, be that sound or unsound.

With regard to your strongly expressed opinion that a "supplementary" or additional examination would be "a clumsy expedient," I beg to remind you that it is precisely the same sort of "clumsy expedient" which the Army and Navy Medical Boards have adopted with infinite advantage to their respective services, and to medical education in general. The value of their returns made to the General Council, proving the grievously defective character of the examinations of the licensing bodies, cannot be over-estimated. Let us hope that your remarks may not induce the war department to abandon their "clumsy expedient."

I am, Sir, yours faithfully,

H. W. RUMSEY.

Cheltenham, August 9, 1866.

#### TREATMENT OF CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have always protested against the College of Physicians or Dr. M. or Dr. T. writing articles in journals or papers to teach medical men how to treat cholera. Its treatment though varied, like that of all other diseases, has now well defined principles, and it ought to be left to those who have been educated in those principles to adopt whatever course they deem suitable.

This literary diarrhœa puts practitioners in a false position; for when I treat a case according to my light, my patient's friends turn on me, and say, "Oh! Doctor, that is wrong; the eminent Dr. M. says it ought to be something else." I have seen three outbreaks of the disease in this country, and my experience is that of most medical men, that at the first outbreak many patients will die of it, do what you please; in a very short time the type changes, and any rational treatment will give good results, more depending on the energy of the doctor and his attention to

general principles both in prescribing and nursetending, than in any peculiar nostrum in the way of plan or medicine.

One would think that the eliminative plan was new, yet in 1832 it was extensively tried. I well knew the trial given to it by the Assistant-Surgeon of the Rifle Brigade in the town where it was then quartered. He gave castor-oil freely, and the idea of curing it with cold water turned his brain and made a lunatic of him. Yet his patients died in a similar ratio with those treated otherwise. It will not do to compare treatment used during one week with that used the next, as the probability is that the latter, no matter what it is, will give better results. I have seen the saline treatment get full play, and it is not to be despised, but will not always answer. I have seen cold water act with very happy results. I have seen it very injurious, bringing on relapse of diarrhœa when it has been checked, and I have seen calomel and opium work wonders. Let men alone, and let them bring their energies, experience, and education to bear on the difficulties that will arise, and I am sure the public will be better served than by running nostrums down our throats.—I am, Sir, yours very truly, J. W. M.

### THIRTY-FOURTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

THE meeting was opened in the Music Hall at Chester, on Tuesday, the 19th inst.

At eight p.m. the public proceedings were opened by the Retiring President, Dr. JEAFFRESON of Leamington; who, on taking the chair, addressed the members present in the following words:—

GENTLEMEN,—At a meeting of the Council of this Association this morning it was unanimously agreed that we should proceed to no general business connected with the Association until we had passed some resolution of condolence with the family, and regret at the loss which we have sustained in the death, of Sir Charles Hastings (hear, hear). If I had a thousand times the eloquence that I have—or rather that I never had—nothing that I could say would express one-half of the feelings which I entertain towards the memory of our inestimable founder, Sir Charles Hastings. In every relation of life he was a man to be loved, to be respected, and, I may say, to be venerated. I was invited by the family, as the representative of your Association, to attend the funeral of Sir Charles Hastings, which I did yesterday. It was a painful duty to me, but it was made to me a happy and noble one, because I felt that by my attendance I represented the feelings of every single member of our Association (hear, hear). I think it may be a satisfaction and a pleasure to you to know that, apart from the feelings which every member of our Association must retain of his memory, I never was more staggered than I was by the demonstration of feeling towards him as a man and a neighbour, in the town of Worcester. Short of any very great public character, or any member of the Royal Family itself, it was impossible that more respect could be shown. It was wonderful to see the number of places—both shops and private houses—that had their shutters up out of respect to the memory of our founder. I may mention one little anecdote, which I am authorized by his son, Mr. George Hastings, to mention. So much was Sir Charles attached to the Association that the last words connected with any matter of business which he used previously to his death—either on the day before or on the morning of his death—were words connected with his ardent desire and hope for the prosperity of this Association. Up to his last breath he retained his loving and kindly feeling towards the members of this Association, and his desire for its permanency and its prosperity (hear, hear). The resolution suggested by the Council has been put into my hands as your President, and I shall call upon Sir Charles's dear

friend, neighbour, and medical attendant to the last, Mr. Carden, to be kind enough to second it. I should not wish to see any kind of discussion upon it. It will be passed unanimously; and it is intended that the resolution should be forwarded to the family. The resolution is as follows:—

“That the British Medical Association, assembled at the general meeting at Chester, desires to express its deep sorrow at the loss the Association has sustained in the death of its much loved and highly esteemed founder, President of Council, and Treasurer, Sir Charles Hastings, who, from the period of its establishment to the present time, has, with singular courtesy and fidelity, exerted his highest powers for the promotion of the best interests of the Association; and that a copy of this resolution be forwarded by the President to the family of the late Sir Charles Hastings, with the condolence of the Association on the bereavement they have sustained.”

Mr. CARDEN (Worcester) said—I can assure you that this is to me a most melancholy and, at the same time, satisfactory duty. I have been called upon by Dr. Jeafrason and yourselves, who knew the value of our late friend, the founder of our Association; and I do most cordially second every word that has been said. But I feel it is unnecessary for me to enlarge upon the character of Sir Charles Hastings. It is well known to you. But I might perhaps say that, having known him intimately through a long and serious illness—more intimately than we can know any one during his appearance in public—throughout that long illness, and at the close of his long, useful, and earnest life, his great wish was for the success of your Association. The last words he said to me were: “When is the meeting at Chester?” I repeated, as I had done before, when it was, and he said, “I may not be able to go to Chester.” Fancy a man with no pulse below the elbow, his soul, entering into the occasion, going beyond his body! Then he added: “If I am not able to go this time it is just possible, perhaps, that I may never join the Association again. If so, I shall only say, as I have always said in my greatest disappointments, ‘God’s will be done!’” He could say no more; but this spoke volumes. It was the character of the man—a high and mighty soul, finding his bodily weakness so great that he began to feel as if his soul should cast away the body that could not carry out his intentions. It was a beautiful sight! You have seen his buoyant manner, and heard his cheering voice, and seen his countenance, which you will never see again, except in recollection; but I can tell you his soul was with you, and I think it my duty, in so many words, to tell you so. I second, most cordially, the vote of condolence and the expression of the feeling of deep regret at the loss we have sustained; and I know further, that the feeling of condolence thus expressed, when received by the family, will be one of the most consoling expressions of feeling that they could possibly receive from any quarter (hear, hear).

Dr. RICHARDSON (London)—I think, Sir, before this resolution is passed those who have worked with Sir Charles Hastings during many years past should give expression to those feelings to which he would have listened with respect and love. I cannot allow this resolution to pass with a silent vote. I must bear my testimony to the kindness, the geniality, and goodness, of Sir Charles Hastings. There were three great attributes in his character which especially call for our attention: first, the wonderful power which he possessed, and which should be diffused through us, of amalgamating men of contrary opinions on many subjects, but of one opinion on those things which most pertain to us as a profession. The more we recognize this particular feature in his career, and feel the spirit in him which welded us together, the more we shall advance in the path of unity and progress (hear, hear). Nor can I fail to recall his untiring industry. I have often thought that for the correspondence of the Association, which he performed alone, many a man would have required a secretary; and he would have been insufficiently remunerated

whatever his salary might have been (hear, hear). For thirty-five years, since he commenced his work, his energy, his industry, through the whole time, is a great and marvellous model to us. And, lastly, I think of that quietness with which he proceeded through all. He went on through the long vista of thirty-four years, always doing something, and least of all presenting through himself that something was done. If we progress, using these three attributes, and sustaining the Association which he founded, we shall best perpetuate his memory (hear, hear). I could not avoid saying these few words with reference to my dear and lost friend.

The resolution was passed unanimously.

The retiring PRESIDENT, after making some business announcements, said—And now, gentlemen, I make my bow. I shall not attempt to make a long speech; but I have to thank you for all the kindness I have experienced from every member of the Association during my year of presidency, and to express the feeling that, though I entered upon my office with great dread and fear that I should not be able to get through all the work in the manner I should wish, yet I owe so much to my good friend our Secretary, and to every member of the Association, that I hope I have not disgraced myself (loud applause). With a loving feeling for the Association over which I have had the honour to preside during the last year, it is no small pleasure, no small consolation, for me to feel that I am succeeded in my office by one so well deserving of your confidence (applause). I am quite sure that Dr. Waters will not be wanting in zeal and kindly feeling; and I feel that he will do more than justice to the office to which you have elected him (applause). Certainly, my year of office has been one of great pleasure in many respects, and of great pain in others. I could wish that at some future time—perhaps when my friend Dr. Waters retires—the dying effort of the President should be to give some little sketch of the history of the year past—some little testimony to the memory of those dear friends we have lost during the year. In this respect, this year has been a very painful one to the Association, as we have lost many valued and very much esteemed friends. I might name amongst them my own cousin, Mr. Jeaffreson of Framlingham, the originator of the ovariotomy operation; my very dear friend Mr. Toynbee, an exceedingly useful member of the Association; and also our most worthy President, Sir Charles Hastings. I have not had the leisure or health to do this; but I do think that, if in future some retiring President should give some slight sketch or memorial of those who have been lost during his year of office, it would be a very valuable addition to the transactions of our Association. With these remarks, gentlemen, I wish you farewell; but I shall continue to hold all of you "to memory dear" (loud applause).

On taking the chair, Dr. WATERS proceeded to deliver the following Address—

#### THE PRESIDENT'S ADDRESS.

GENTLEMEN,—In the year 1859, when I filled the post of President of the Lancashire and Cheshire Branch of this great Association, on the occasion of its meeting for the first and, as yet, only time in Cheshire, I gave expression to my gratitude for the signal mark of regard and confidence then conferred on me; then, as now, I stated that the esteem of my professional brethren, as it is one of the most worthy, so has it ever been one of the most cherished objects of my life.

I have an undoubting trust that this same feeling will ever animate me; it burns within me now as vividly as in the most sanguine period of existence when, rich in the possession of that priceless appanage of youth, a warm, confiding heart, unchilled by the trials of life, the future spread itself out before me bright and unclouded.

The present is an occasion when I may, perhaps, be excused saying some few words of myself. In doing so I am not actuated by any vain-glorious spirit, but for those who have to follow the older members of any profession there is not unfrequently some little advantage to be

derived in the way of guidance and instruction from those who have preceded them. The maxim I would seek to establish is, that, though there is much of uncertainty and of accident in the career of most men, steady and persevering application, however unassuming, generally reaps all, and not unfrequently more than it is strictly entitled to; but above all, without referring to the delights incidental to extended knowledge and increase of intellectual power, it confers rewards of which no instability of fortune can deprive the possessor.

During the course of my professional career, marks of great kindness have been conferred on me by the teachers under whom I studied, as well as by those in community with whom I worked, for which I scarcely dared hope, but which, for that very reason, I value the more highly.

Gentlemen, standing before you in my present position, one of the highest and most honourable to which any man whose lot is cast in the provinces can aspire, while dreading the responsibility devolving on me, and which, but for a conviction that your kind consideration and forbearance will pardon my shortcomings and more than supply all my deficiencies, I must have hesitated to accept, it may readily be believed that I regard this day as the proudest of my life. The personal gratification incidental to the day is, however, alloyed by a deep and solemn feeling of profoundest grief. This, the thirty-fourth anniversary of the British Medical Association, the first held in the time-hallowed and ancient city of Chester, takes place under circumstances previously unknown in the annals of the Association. The founder, the venerated founder of the Association, is no more. Only a few days back, on the 30th of last month, in the seventy-third year of his age, the pure spirit of Sir Charles Hastings winged its flight for a higher existence, leaving us to regret and lament his absence. As is the grief of a loving son mourning the loss of a wise and good father, to whose fostering care and affection, to whose untiring devotion, he is indebted for all of happiness and prosperity with which he is blessed, such is the deep pervading sentiment of sorrow experienced by every member of the Association for the death of him we now deplore, who will no longer cheer us by his genial presence, elevate us by his noble aspirations, stimulate us by his achievements, and guide us by his wise counsels and great experience.

During the past year death has, indeed, fallen heavily upon us in removing many a valuable member. Without attempting to enumerate all, some names I cannot refrain from mentioning. The mortality amongst medical men from contagious diseases is so heavy as to raise their death-rate to a height which, if it fell on the general body of the people, would soon solve the difficulty of disposing of our surplus population. The disease, which of all others specially decimates their ranks, is typhus. All members of the profession are, of course, subject to it; though it necessarily falls with greatest weight on the medical officers of public institutions. With respect to other contagious diseases, for instance, cholera, intervals sometimes of great duration occur during which the disease is scarcely met with, but our public hospitals are never free from typhus. In greater or less degree, cases always present themselves; and owing to the length of time over which they extend, those in charge of them are peculiarly exposed to take it. Drs. Stokes and Cusack have shown that in Ireland, during the twenty-five years prior to 1843, 560, out of 1220 medical men who were attached to public institutions, suffered from typhus fever; of whom, 28 had it twice, and 9 three times. The tables from which these facts are drawn do not extend over a period of exceptional mortality, for they stop short of the fatal epidemic of 1847, when out of every three deaths occurring in Ireland amongst medical men, about two were from typhus, the exact proportion being 1 in 1.55. In Chester, during little more than a twelvemonth, we have lost Dr. Hutchinson Powell, one of the physicians to the Chester Infirmary; Dr. Lewis Brittain, house-surgeon, the eldest son of Mr. Brittain, senior-surgeon to the Infirmary,

and our valued associate; and Dr. Hughes, also house-surgeon; together with Mr. Jones, one of the pupils. All four have fallen a prey to typhus!

Gentlemen, it was in discharge of the holy and self-sacrificing ministrations for which our profession is so pre-eminently distinguished, that these our brethren, free from the taint of worldly gain, wholly unrewarded for their priceless services, were thus immolated.

One only, Dr. Brittain, was a member of our Association, but all intended to have joined it. Amongst the victims of fever I would, however, specially mention our associate, the late Dr. Barker of Bedford. It has in numerous instances been observed that those whose studies have been directed to any special disease, or any distinct organ or portion of the frame, have themselves experienced the suffering incidental to it. In this way Laennec succumbed to pulmonary consumption; Reid of St. Andrew's, to the most painful of diseases which afflict mankind, and involving, in his case, the very nerves whose influence his numerous experiments had done so much to elucidate. So Dr. Barker, in dying of typhus, also succumbed to one of that class of diseases which it was his effort to prevent. A short time only elapsed after the celebration of last year's anniversary at Leamington, where Dr. Barker received from the hands of him whose name it bore, the Hastings medal for his prize memoir on disinfectants, ere we all heard of his being stricken by fever and perishing under it—another martyr to professional duty. Alas! in one short year, both he who received and he who presented the valued reward of competitive merit, have been lost to us by death! The recent death of Mr. Toynbee has deprived us of another of our most valued associates, one who helped to sustain the reputation of England by the high rank he attained in that department of the profession to which he devoted himself. Still, high as were his professional attainments, and in these no man excelled him, he was no less remarkable for his open-handed charity.

There is one charitable institution specially connected with the British Medical Association—one which in no way interferes with the Royal Medical Benevolent College at Epsom. The establishment at Epsom founded by our respected associate, Mr. Propert, who, as a Welshman, is an honour to the Principality, exercises a wide and most beneficial influence, and enjoyed the distinguished honour of having the late and ever-lamented Prince Consort as its patron. It affords a sound education, such as will bear comparison with the best of our public schools, to the sons of medical men at a very moderate charge, and to a certain number of orphans and fatherless free of all expense. It also supports as pensioners superannuated and disabled medical men or their widows. The numerous applicants to fill the vacancies that occur, far exceeding the resources of the institution, were incontrovertible evidence of the urgent necessity for its existence. Acting as I have done for several years as one of the Honorary Local Secretaries to the Epsom College, I need not say that it has my warmest support, and that I hope not only for its continuance on its present scale, but that I look forward to its great extension. To secure the great advantages offered by the Epsom College, a system of arduous and expensive canvassing is resorted to, which, when continued year after year, is almost heartbreaking, and crushes those whose influence is not sufficiently great to insure success. This charity, however, is not specially connected with the Association, as is the Medical Benevolent Fund, which is conducted on a plan different to that of the Epsom College, and occupies an entirely different field. The chief object of the Medical Benevolent Fund is to grant temporary rather than permanent relief; to obtain assistance from it, all that is required is to have the case of distress well authenticated and recommended by two or more members of the profession. The application is then at once considered, and relief granted. No canvassing and no publicity are necessary, and if the saying, *bis dat qui cito dat*, can ever

apply, most unquestionably it attaches to the aid granted by the Medical Benevolent Fund.

It is with reluctance that I have trespassed on your time with these details, but, though well-known to many of us, they may not be equally so to all our associates; and I have been influenced to do so by the fact of the late Mr. Toynbee having devoted much of his valuable time, abstracted from incessant professional demands, to enlarge the sphere of its operations. The unobtrusiveness of the method in which this Fund dispenses its relief, accorded with that pursued by Mr. Toynbee himself in the exercise of his private charity. Hence his special support of it, on one occasion giving, I believe, £500 towards it; but, above all, bestowing on it his time, more valuable even than his pecuniary munificence. The melancholy accident by which he met his death was in harmony with his life: while seeking, by experiments on himself, to discover means for alleviating the sufferings of others, he sacrificed his own life in its fullest prime.

In Dr. Connolly we have lost another chief, who, as long as health permitted, always attended our meetings, and by his exquisite literary taste, his high professional attainments, and graceful urbanity, contributed largely to their attractions. In him society has lost a true and practical philanthropist; but the influence of his life will remain in all that he has effected for the humane treatment of the insane, and for the aid he afforded in founding the first asylum in this country for the reception and education of idiots, awakening and training their affections, developing their feelings, and opening a new world to those whose existence before was a dark and dreary blank. Dr. Connolly was one of the earliest members, and one of the pillars of the Association; and, with Forbes, Johnstone, and others, aided Sir Charles in founding it. One by one these early friends passed away, leaving Sir Charles almost their only survivor; and it became painfully evident to all who attended the latter anniversaries, that the conviction was deepening in his mind, that the day was not far distant when he also would be summoned.

At the Leamington meeting, he appeared so much like his former self, so much better and stronger than the years before, and spoke with so much vigour and power, that, when accepted for Lady Hastings and himself, my proffered hospitality for this meeting, I fully calculated upon the pleasure of receiving them. I know that Sir Charles Hastings had for many years looked forward to a meeting being held in Chester; but little did I imagine at Leamington that, when we assembled, he would be absent, and that I should not only lose the ever ready counsel of him, the grand object of whose life was the promotion, the growth, and the increase of the influence for good of this Association, but that I should have to mourn his death. This is the first occasion on which the person who has to preside over your proceedings, has not been aided by the experience of him who has never missed one of its gatherings. The ship he built is fairly launched, and the pilot who so long guided it has departed. It now remains to be proved whether others can safely navigate it, and whether his great ambition to fix this Association on the firmest possible basis has been realised.

Gentlemen, as I have before stated, in accordance with our founder's wish, we are met together in Chester; and, in the name of the profession, I give you a most cordial welcome, and hope the meeting will prove a successful one. In objects of interest, Chester can be nowhere surpassed. It is no modern town; it boasts an antiquity of nearly two thousand years, dating from the occupation of the Romans, when the 20th Legion of the Empire was encamped here. The remains of Roman antiquities are extremely numerous; but of these, in your perambulations through the city, you will acquire a far better knowledge than from any description of mine. The most important fact for us, is the existing unmistakable evidence that the Romans built their city, with a view to the health of its inhabitants, on a foundation of new red sandstone, at an elevation admitting of easy and effectual

drainage. The city was clearly characterised by a high state of civilisation. It possessed at least two sets of public baths, and many fine public buildings, the remains of which are occasionally disinterred where least suspected to exist. These remains generally lie from four to five or more feet below the present surface of the ground, such being the accumulation of soil during the time that has elapsed since their erection. The remains also show that pure drinking-water was much valued, and that hygienic measures were carefully carried out; better, probably, than they have been at any subsequent period. With the Roman occupation and civilization, Christianity undoubtedly came in. The theory has been maintained, that existing savages are the descendants of civilised races. In some cases, this may be the case; in others, however, much more probably not; but in no way should we be justified in terming the Saxons savages, though it is certain and very remarkable that, under their rule, the arts and comforts of civilised life were replaced by earthen floors strewn with rushes, and Christianity by Paganism. In Wales, where the Saxons did not penetrate, Christianity remained. In the neighbourhood of Mold, a town twelve miles distant, the Christians under Germanus gained the Hallelujah victory against the Picts; and about twelve miles up the River Dee, where no vestige of a monastery now remains, but simply a church that replaced it, an establishment numbering two thousand monks existed, who resided there when Saxon England was Pagan. I would also mention that, in the neighbourhood of Chester, Delemere Forest is situated, which, under the rule of Ethelfleda, daughter of Alfred the Great, was the site of an important station. The hundred in which it is situated is named Eddisbury, obviously a corruption of Ethelfleda's borough. Anyone now visiting it, and perceiving no trace of ruins of any kind, would never imagine it to have been the seat of a large population, though yet an undoubted fact.

That a civilisation of so high an order, and marked by that special attention to the preservation and promotion of good health which characterised the Romans—a civilisation which could not merely have occupied this portion of the kingdom, but which palpably extended wherever the Roman rule prevailed and was moreover refined by the softening influence of Christianity—that such a civilisation should have been absolutely extinguished and replaced by barbarism and paganism, and that we should now have the proof of the change at our own doors, is in the highest degree worthy of attention and reflection, and should make us, who, by our calling, are the conservators of the public health, carefully guard against the influences which tend to deteriorate it, for degeneracy of body and degeneracy of mind unquestionably coincide. In Chester, it took years of suffering, during which the penalty for neglected hygienic measures was paid in the form of fearful mortality from the sweating sickness, and from repeated attacks of plague, before the inhabitants again awoke to the necessity of drainage, of water-supply, and of public baths, all which have only very recently been attended to.

Whatever may be the causes that bring together large bodies of men, whether the mustering of great armies, or the demand for labour resulting from manufactures or from commerce, neglect of hygienic rules is, under such circumstances, inevitably followed by sickness and premature death. The terrible lesson experienced by our army in the Crimea, where a mortality of 35 per cent. from disease in the short space of seven months, extending from October 1st, 1854, to April 30th, 1855, decimated its ranks, is still fresh in the memory—a rate of mortality which by disease alone, without reckoning the casualties of the battle-field, would in twenty months have swept away every living soul of one of the finest armies that ever left our shores. The mortality above given does not comprise the numerous men whose health, broken by the privations under which their comrades, happily for them, more speedily fell, have since their return succumbed, or are still dragging on a weary suffering life of hopeless illness. That this sad state of things might have been prevented, is

unquestionable; for the officers, who from their private resources, were to some extent independent of government care, did not suffer equally with the men; and when the reclamations of the medical officers (for our professional brethren did not allow our noble soldiers to die from disease without pointing out the neglect that occasioned it) at length succeeded in obtaining their demands, then the mortality rapidly diminished.

The French profited in their Italian campaign by the experience of the Crimea; for, owing to the admirable arrangements directed by the Emperor, at the instigation of the distinguished surgeon Baron Larrey, notwithstanding the monster armies assembled, notwithstanding the heat, which was excessive, and the unfavourable telluric influences incidental to a campaign in Lombardy, neither hospital gangrene, typhus, nor other contagious disease, prevailed to any extent. If the English nation, equally with the French Emperor, should thus profit by the Crimean lesson, then our gallant men will not have died in vain; but it is a lesson that the English nation seems too frequently to require; for in 1809 the same feeling of horror, that was engendered by the Crimean losses, thrilled through all England at the result of the Walcheren expedition, when, out of every 1000 men, 167 only were lost by wounds, and 332 by disease. The medical profession in this country is, however, year by year increasing in influence, and bringing its weight to bear upon questions of public health, although it has but scant encouragement afforded it.

Since our last anniversary, Cheshire has been heavily visited by the cattle plague. Well do I remember how the alarm was sounded by our associate Dr. W. Budd at Leamington this time last year. No one who then heard him can forget the deep impression he stamped on the minds, and not only on the minds but on the feelings, of those who listened to the moving, eloquent language in which he predicted the sad results which would inevitably follow the neglect of the precautionary measures which experience had too surely proved could alone avail. The preventive measures he advised were of no hypothetical character; they had been tested and found effectual in countries actually adjoining infected districts, and with entire success; they were carried out in France, where the disease had actually penetrated, and with equally good result; they were peculiarly easy of application in England, girt as she is by the sea, and capable of complete isolation. The measures suggested were marked by no taint of novelty; but, as with the Walcheren, as with the Crimean expedition, the teaching of past experience was disregarded. A century back, the plague had passed over the herds of this country, carrying desolation in its track—desolation, the effects of which, in the ruin it entailed, it took a generation to erase. With all this knowledge pressed upon the authorities, no adequate measures of repression were enjoined. Step by step the disease advanced, until at last it invaded our Cheshire herds. Gentlemen, I did my best at that sad and anxious time to have the disease stamped out; I addressed one of our county members, and urged the impropriety of attempts at cure, and showed that no amount of private success could be otherwise than injurious to the public weal; for that the very process of cure must entail the spread of the disease.

I urged that the visitation was a national calamity, and should be met by a national tax; that it was not the agricultural interest which was alone involved; but that every member of the community, from the labourer upwards, would, in the price of meat, be affected, and that the drain on the public purse would be insignificant, if not imperceptible, if the pole-axe were resorted to in time. I endeavoured to impress upon him that it was the duty of the executive to anticipate and to guide public opinion, rather than be governed by it; and that, at the expense of present unpopularity, it should at once enforce such measures as superior information and intelligence dictated, and allow subsequent events to justify them. The gentleman to whom I thus applied endeavoured to influence others.

Time, however, travelled on, the disease extended; and the reply he then generally received was, "We are not going to pay for your losses in Cheshire."

The pole-axe system was then put in force, and killing was adopted with a view to compensation; but in very many, if not the majority of instances this was only done when the animals were at the point of death. As far as Cheshire was concerned all the misery and loss the disease could effect was accomplished; the infection was so general that no killing could save the remaining stock. The pole-axe system in Cheshire, at that time could only be of by advantage to those parts of the kingdom not yet invaded the disease; and those gentlemen who replied to my friend, "We are not going to pay for your losses in Cheshire," may yet pay the the penalty of their selfishness in the loss of their own herds.

One consequence of the disease has been the selling off of a large quantity of hay, which has been forwarded to other parts of the kingdom. As yet, no ill results seem to have followed; it may be that the hay, owing to the abundance of grass at this season of the year, has only been used for horses, and not for cattle. It is highly probable that much of this hay contains the fomites of the disease. Let us, however, hope that no ill results will occur. The face of Cheshire is completely altered by the disease; farms where cattle abounded are now stocked with sheep, for which our pastures are ill adapted. A loan of £300,000 has been obtained from the public purse to compensate those whose cattle were killed, and rates extending over thirty years will be levied to pay off interest and loan. Such a proceeding is simply a loan to the sufferers, to be returned by instalments. For two years nothing is to be repaid, for the simple reason that the farmers have not wherewithal to pay. Such is a short sketch of the progress and effects of the cattle plague in Cheshire by an eye-witness.

The subject of contagious diseases has always excited interest in Chester. The late Dr. Thackeray, whose name is connected with our principal charities, especially the Infirmary and Blue-coat School, was one of the early members of this Association, and to whose memory a monument has been erected by his fellow citizens in our picturesque cemetery, placed £50 at the disposal of the Association, as a prize for the best essay on fever. Another of the medical celebrities of Chester, Dr. Haygarth, at the end of the last century, with a view to the prevention of infectious diseases, inculcated the necessity of isolation in their treatment, and the adoption of fever wards. It is one of those matters of which the profession in Chester is naturally proud, that the views he so strenuously advanced and maintained, and which at the time were met by uncompromising opposition from many, are now generally adopted.

The cholera at present, more than any other disease, occupies public attention. On its last occurrence in Chester, the worst possible course was adopted with regard to it. The cases were treated, as they occurred, in the localities where they originated, spreading the disease around, and so continuing until it wore itself out. The authorities at present are fully warned against the danger of pursuing a similar plan, and are taking steps to insure, as far as practicable, the isolation and separate treatment of the disease. There is one point of deep interest connected with Chester as regards cholera, and has a direct connexion with the conclusions arrived at by Dr. Snow in his pamphlet on cholera, published in 1849 and again in 1855, and by the Registrar-General in the reports on the epidemics of cholera in 1848 and 1854. Dr. Snow showed that the cholera in London was more general in districts where the population drank water contaminated by sewerage than elsewhere. This was particularly the case with the notorious Broad-street pump, which, as supplying water of a pleasant, bright, sparkling character, though thus contaminated, was in general request. It was mentioned in the papers recently that the handle of this pump had been repaired, but happily Dr. Lankester has since interfered and ordered its removal.

The supply of water to Chester is derived from the River Dee within the tidal influence, the spring tides flowing some miles above the point whence the water is pumped. The water, however, is only pumped into the reservoirs, which immediately supply the city when the tide is out. This constitutes a source of objection to the present source of supply; there is, however, a still graver one to be urged, and this affects the very body in whose hands the interests of the community are lodged. In reference to this point I must mention that in the reports I have referred to the following facts are stated. I shall select provincial towns as specially bearing comparison with Chester. During the epidemic of cholera in 1832, 1000 cases occurred in Exeter, of which 347 were fatal; the water supply at that time was derived from the river, and was contaminated. In 1834 the water supply was improved, being drawn from the river two miles above the town, and when the epidemic of 1849 occurred, there were only 44 cases, and those chiefly amongst strangers. In Dumfries in 1832 and 1849, when the supply of water was both scanty and impure, the disease raged with fearful virulence; after the second visitation a better supply, perfectly free from taint, was procured, and in 1854 the place was very lightly visited by cholera. I might multiply similar cases, but those I have given sufficiently show the importance of pure drinking water.

In Chester, as in most other towns, we are dependent on a water company for the convenience and advantage of our water supply. The water, at the time of their establishment, was drawn from a point of the river above the city; but, with the extension of the city, houses have now been erected beyond it, and the company are at present laying down pipes extending above them. Complaints have not unfrequently been made against the Water Company, and this has been done by members of the Town Council, although there is a source of pollution of our river for which I believe the Town Council is responsible. Some fifteen years back, the sewerage of this city was remodelled. Difficulties present themselves in all undertakings; and the difficulty in this instance was the disposal of the sewerage. We have a sandy alluvial soil within easy reach of the city, thirsting for all the manure we can bestow on it, and certain to repay it in abundant crops; but, be this as it may, obstacles existed to obtaining an outlet, and, in consequence, the Town Council decided on discharging the sewerage of the city, yearly increasing in population, into the River Dee, but a short distance below the point whence the present water supply is obtained. At the point where the sewers enter the river, a bank of deposit is rapidly forming, and the tide passing over it necessarily carries upwards beyond the water works the influence to be exerted by the excreta of the inhabitants. I have ventured to call attention to this subject, because, after the experience of Exeter and other places, it will be interesting, should cholera invade the city, to watch its influence, and learn what, if any, may be the effect on the citizens resulting from this pollution of their river. I have often seen the dark iridescent pellicle due to it floating on the surface. The water supply of Chester is trammelled by the restrictions which ever apply when an article of such prime necessity for private individuals or the public good rests in the hands of a private company. The occupiers of low-rented tenements, unless the water be supplied through their landlords paying the water-rate (and this is by no means generally done), are dependent on surreptitious supply, or supply from private pumps and fountains; and the very houses and localities which, for the sake of the public health, stand most in need of cleansing and purification, are thus left without the means of effecting it. All sanitary reformers maintain that the supply of water should be free as air and light. The window tax being abolished, the time has arrived when, wherever practicable, the supply of water should, for the public good, be taken up by the local authorities, and a general water-rate levied, which would bring all the property of

the city under contribution, and make the supply a profitable one. In the interest of the public health, the plan of proceeding might be well urged on the Government, which would thus do something to counteract the ill effects resulting from the great facilities afforded for obtaining less innocent beverages.

When the diversion of the sewage from our lovely river is effected, and when the city takes into its own hands the supply of water to its citizens, so as to supply it to all, a great and most beneficial advance will have been made in our sanitary arrangements.

Gentlemen, in the remarks—the discursive remarks—with which I have opened this anniversary, I have avoided touching on the subjects to be treated by the readers of the addresses, who are so much better equal to dealing with them than I am. I have touched on some matters of local interest, but the more important business of the meeting I resign into other hands, and again thank you for the kind manner in which you have received me.

(To be continued.)

### THE BRITISH MEDICAL ASSOCIATION IN DUBLIN IN 1867.

We have much pleasure in stating that the British Medical Association has accepted the cordial invitation of the University of Dublin, of the King and Queen's College of Physicians, and of the Royal College of Surgeons in Ireland, to meet in Dublin in 1867. We are satisfied that the Association will meet with an Irish reception, which will, doubtless, be of the proper kind, under the Presidency of Dr. Stokes. We publish in this number part of the proceedings of the late meetings, including the President's Address; and we have to apologize for the non-appearance of several communications in consequence of the pressure on our columns from this cause.

## Notes on Current Topics.

**THE TREATMENT OF CHOLERA.**—The *Lancet*, in some recent numbers, contains a paper by Dr. Painter, "On the Theory and Treatment of Cholera." It is written with a strong conviction based on experience, that the theory of elimination is not a safe one in practice. He states that if he had seen no cholera his reason would be perhaps satisfied with the eliminative theory; but, having seen strong men drained of their fluids and dying in a few hours, partly at least from exhaustion, he would prefer a different treatment to attempting to purge out the poison. He would rather fit his theory to his practice as, at any rate, the safer, and adopts a theory for this as well as some other epidemic diseases, which he calls that of *conversion*. He contends that in typhus, for example, there is no evidence that all the poison germs are thrown out, although some may escape with the excretions and convey the disease. The greater portion of the poison is probably oxydized in the body, or otherwise converted, should the patient have sufficient power to effect it. Again, he argues that in cholera there may be nothing to throw out, as the deranging influence may be imponderable in its nature, and only effect, perhaps, the nerves; the diarrhœa arising from a peculiar derangement of nutrition.

But, granting that there be a material thing to cast out, he holds that it would be rational to endeavour to restrain the too rapid outflow that is likely to kill by exhaustion.

He advises instant arrest of diarrhœa previous to collapse by astringents and opium; but during collapse opium to be carefully withheld, and trust to be then placed in brandy, calomel, and cold water, the application of the "wet sheet." Nearly two-thirds of his collapsed cases recovered. He suggests, in regard to the contamination of water theory, that patients should be asked if they are beer or water drinkers. The inference is plain. If bad water be the only source of contagion, drinkers of beverages made of boiled water, as beer, tea, and coffee, ought not to suffer attack.

**THE ESK POLLUTION CASE.**—This expensive suit is now being heard before the Lord Justice Clerk and a special jury, and excites a great amount of interest. The action is brought by the proprietors on the banks of the River Esk, the Duke of Buccleuch, Lord Melville and others, against the paper makers, whose mills are said to have so polluted the stream as to render its water totally unfit for domestic purposes. The stench which now arises from the river is declared to be abominable and unhealthy, and the object of the action is to interdict the paper manufacturers from allowing the refuse of their works to flow into the river. A large number of medical and scientific gentlemen have been summoned as witnesses, including Professors Christison and Maclagan of Edinburgh; Miller of King's College, London; Penny of Glasgow; Drs. Gamgee and Crum Brown of Edinburgh, &c. &c.

**URQUHART v. BONNAR.**—This case which has been so often alluded to in these columns, was tried for the third time before Lord Brough and a jury on Monday and Tuesday last week, and the verdict, which on this occasion was unanimous, was again in favour of the pursuer. The jury found that the assignation of the life policy had been signed by the deceased John Urquhart when he was under essential error as to its nature and effect, induced through undue concealment on the part of the defender Dr. Bonnar. We trust that this may be the last we shall hear of this tedious and painful case.

**THE RIVER LEA.**—The report of the Registrar-General directing attention to this water has produced a somewhat animated correspondence in the daily papers. It was to be expected that the company supplying this water would say all that could be said in its favour, and, to do them justice, analysis has shown their water to be equal to that of other companies. But the force of the epidemic continues to be spent in the district drinking their water, and from a careful examination of the charges brought and the replies offered, we feel that it is by no means certain that the water could not have been contaminated. We are, therefore, glad to learn that the Metropolitan Board are actively erecting a temporary pumping station, in order to divert some of the sewage. Further, a quantity of water from the Thames has been let into the Lea, from which an improvement in its condition may be anticipated. At the meeting of the board Mr. Bazalgette stated that £250 a week was being expended in deodorization.

**THE NEW PUBLIC HEALTH ACT OR THE SANITARY ACT, 1866.**—This important measure, to which we alluded in our last issue but one, has received the Royal assent. It contains many important and valuable provisions, and will go a long way towards placing our sanitary regulations on a sound basis. The Act, containing sixty-nine sections, is divided into four sections (with two schedules), and is to be

cited as the "SANITARY ACT, 1866." Its chief characteristic is that of rendering compulsory many things that have been hitherto more or less optional. Thus, inspection of districts to ascertain the existence of nuisances, prosecutions for such nuisances, provisions for good water supply and good drainage are no longer to be left to the option of the local authorities, but are from this date obligatory upon them. A more detailed analysis of the Act will be furnished our readers in the next number of THE MEDICAL PRESS AND CIRCULAR. In this column we have only to express our gratification that the Bill has become law, and our approval of many of its provisions, among which we may particularly cite the clause empowering any twenty inhabitants of a district to appeal to the Home Secretary on sewage matters; that enabling any nuisance authority, on the certificate of any legally qualified medical practitioner, to order premises to be cleansed or disinfected; those regulating the conveyance of persons suffering from infectious diseases; those for the prevention of overcrowding, and for closing cellars used as dwelling places; for founding hospitals for the sick, and suitable places for the reception of dead bodies. There are numerous other provisions, all deserving careful analysis, and the fourth part of the Act (with the first schedule) is devoted to the application of the measure to Ireland.

**LONDON WATER SUPPLY.**—No time could be more favourable for bringing forward the subject of a better water supply for the metropolis, and we trust that this national object may be attained in spite of the vested interests, which are likely to oppose every proposal. It is stated that surveys are now being made with a view to seeking an Act of Parliament, to divert and utilize all the sewage of the towns on the Severn above Tewkesbury, and taking water just above that town, convey it to reservoirs about nine miles off, at such an elevation as will allow the water to pass from the reservoirs to London, delivering it a sufficient height to afford a constant supply at high pressure. It is hoped that the continual flow of the water such a distance would tend to oxidize any organic impurities. The cost of this undertaking is estimated at £3,000,000, only one-third the amount of the Welsh project, which found favour with some persons. Another scheme is to obtain a supply of water from the sources of the Wye, which drain the districts in the vicinity of the Plymlym range, where there is a yearly rainfall of seventy inches. The cost of this plan would be some £5,500,000. Other proposals will no doubt be coming forward. No more important subject could have the attention of our engineers and the public. Whatever the cost London ought to be supplied with pure water in a manner to obviate the least chance of sewage contamination. Every house in the metropolis should be furnished with such water. It is time to put an end to the monopolies of mere commercial speculations, and make the supply of water the duty of some such body as the Metropolitan Board of Works.

**CHOLERA MIST.**—In a remarkable letter to the *Times* the Astronomer Royal calls attention to a peculiar blue mist that he had observed in Greenwich Park during the prevalence of the cholera epidemic in 1854, and which has again made its appearance. Mr. Glaisher says, that "no meteorological choleraic conditions had been present up to July 22." After this he was away, and on his return to the Observatory, on the 30th July, he at once saw the same phenomenon that he had remarked in September, 1854. He says he has "examined the atmosphere daily for this blueness, particularly during the last twelve months, and never seen anything like it since 1854." The peculiarity of the mist is its permanence, for, while ordinary mists pass away with a wind pressure of half a pound per square foot, this remained for a whole week,

with wind blowing for sixty or seventy hours together at a pressure varying from a quarter of a pound to nine pounds per foot.

Mr. Glaisher has also observed a yellow mist "connected with the prevalence of scarlatina."

The observations of a man like Mr. Glaisher are not likely to be neglected, nor are they open to the objections that might be urged against those of inexperienced scientific observers. Mr. Lowe, from his observatory near Nottingham, writes to say, that his attention had been attracted to a similar appearance, of which he had taken special notice, "thinking it possible to be a comet detained by the earth's attraction." Nor is this the first occasion of this phenomenon being described as possibly connected with cholera, for Dr. Cooper described a "thin transparent bluish haze hanging over the spot, and not affected by the wind," as having been noticed by persons on board our men of war at Varna, just before the outbreak of the cholera there, as well as at St. Christopher, "just prior to the outbreak of the disease in that island in November, 1854."

The subject is very interesting, and if at first somewhat startling, is worth the notice of other observers, which Mr. Glaisher asks for.

**GRADUATION IN MEDICINE (EDINBURGH).**—The ceremony of graduation in medicine took place on Wednesday last in the Assembly Hall. The venerable principal, Sir D. Brewster, presided, and Dr. Christison addressed the graduates on "The Constitution and well-being of the Medical School of the University." There was a large attendance of professors and of the general public, every part of the large hall being completely occupied. The degree of M.D. was conferred on twenty-one candidates; the degrees of Bachelor in Medicine and Master of Surgery on thirty-nine; and the degree of Bachelor of Medicine alone on three gentlemen. The following is a correct list of the candidates, with the titles of their theses, &c. :—

*Candidate who received the Degree of Doctor of Medicine under the new Statutes.*

Groves, Charles H., B.A., M.B., and C.M., England.

*Candidates who received the Degree of Doctor of Medicine under the old Statutes.*

Allshorn, Adolphus Hahnemann, England. On Tubercular Meningitis.

Briggs, Edwin Adam, England. On Mercury, its Cholagogic Action.

Cowie, Robert, M.A., Shetland. On the Inhabitants of the Shetland Islands.

Crane, Charles Albert, England. Some Remarks on French Hospital Practice.

Henderson, William Patrick, Tuscany. On Acute Hydrocephalus.

Hewan, Archibald, Jamaica. On Malarial Poisoning.

Jones, James, England. A Report of Certain Cases in the Clinical Wards, Session 1865-66.

McDowall, Thomas William, Scotland. On Tumours of the Jaws.

McNab, William Ramsay, Scotland. On the Development of Leaves.

Miller, Andrew, England. On Uric Acid Gravel.

Moniot, John Adolphe, East Indies. On the Diseases of Joints.

Murray, William Berkeley, Barbadoes. On the Hereditary Transmission of Disease.

Rawlings, Joseph Henry, England. On some Cases of Albuminuria.

Ritchie, Alexander Ramsay, Scotland. On a New Modification of Ecraseur, and its application to Decapitation of Fœtus in Crossbirths.

Thomson, John Robert, Scotland. Clinical Observation, illustrating some Forms of Hepatic Disease.

Watson, George, Scotland. On Ovarian Dropsy.  
 Weston, George Blyth, South Carolina. On Yellow Fever.  
 Whittle, Alfred, England. On Typhus Fever.  
 Williams, William Jones, Wales. On Wasting Palsy, or Progressive Paralysis.  
 Wright, Robert Temple, England. On the Fœtal Pulse-rate, as a Means of Predicting the Sex.  
*Candidates who received the Degrees of Bachelor of Medicine and Master of Surgery.*  
 Aldren, Robert, England. On an Epidemic of Small-Pox.  
 Anderson, David Hawley Burn, Scotland. On the Action of Remedies.  
 Anderson, Francis Henry, Jamaica. On Pyæmia.  
 Andrew, James, Scotland. On Apoplexy.  
 Bent, John Francis Vincent, England. On Diphtheria.  
 Brown, Joseph, Scotland. On Enteric Fever.  
 Brunton, Thomas Lauder, Scotland. On Digitalis, with some Observations on the Urine.  
 Cadell, Francis, Scotland. On Cataract, and the Operations for its Removal.  
 Downie, Kenneth Mackenzie, Scotland. On Excision of Joints.  
 Drummond, Alexander, Scotland. On Tedious Labour.  
 Fulcher, George Frederick, England. On the Change of Type in Disease.  
 Gell, Thomas Silvester, England. On Urethritis, and its Complications.  
 Gordon, John Mackenzie, Scotland. On Acupressure.  
 Hair, Philip, Scotland. Observations on the Arrangement of the Muscular Fibres of the Alligator.  
 Howells, Thomas, England. On the Excision of the Knee-joint.  
 Hunter, William Brown, Ireland. On Hygiene.  
 Husband, Henry Aubrey, Jamaica. On the Treatment of Nervous Affections following Gunshot Wounds and other Injuries.  
 Lowe, George May, England. On the Structure, Relations, and Functions of the Ligamenta Rotunda Uteri. On the Diagnosis and Treatment of the Retained Menses. On the Occurrence of a peculiar Crystalline Substance in a certain form of Dilatation of the Bronchi.  
 Macbeth, John, M.A., Scotland. The Influence of the Nervous System on Nutrition.  
 MacLaren, George Gilbert, Scotland. On Rheumatic Fever.  
 Malins, Edward, England. On Fatty Degeneration of the Placenta.  
 Moir, John Wilson, Scotland. On Excision of the Knee-joint.  
 Moon, Charles, Scotland. On the Pathology, Symptoms, Diagnosis, and Treatment of the Gastric Ulcer.  
 Munro, William, Scotland. Moral Insanity, with especial reference to its Manifestation as Kleptomania and Dipsomania.  
 Paterson, Alexander, M.A., Brazil. On Typhus Fever.  
 Pullar, Alfred, Scotland. On Glaucoma, its Nature and Treatment.  
 Ramsay, James, M.A., Scotland. On Syphilization and the Syphilitic Virus.  
 Rhind, John, England. On Stricture of the Urethra.  
 Sharp, David, England. Additions to the Catalogue of Scottish Coleoptera.  
 Shaw, Robert, Scotland. On Cutaneous, or Exanthematic Typhus Fever.  
 Smith, John, Scotland. On Aneurism.  
 Steven, Alexander, Scotland. On Angina Pectoris.  
 Stewart, William, Scotland. On Fistula in the Genito-Urinary Organs of the Female.  
 Stolterforth, Henry, M.A. Cantab., England. On the Influence of the Mental Faculties both as a Cure and Cause of Disease.  
 Sykes, Walter John, England. On the Human Voice.  
 Symes, William Henry, England. On Accommodation of the Eye.

Trentler, William John, Bengal. On the Evolution of Light from the Living Bodies of Man and the Lower Animals.

Watson, John, Douglas, Scotland. On the Poison-resisting Power of the Hedge-Hog.

Yarrow, Thomas, Scotland. The Pathology, Complications, and Connexions of Rheumatism.

*Candidates who received the Degree of Bachelor of Medicine.*

Buchan, Peter, Scotland. Ileus, its Pathology and Treatment.

Haughey, Alexander Richardson, Ireland. On Asthma.

Wigg, Henry Carter, England. On the Physiological Action of Nitro-Benzole.

A Gold Medal has also been awarded to Mr. Franklin Gould, for his thesis "On the Thermometer in Disease;" but as he has been unexpectedly called to go abroad, the conferring of his Degree, and the presentation of the Medal, are unavoidably postponed.

## Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.---The following Members of the College, having undergone the necessary examinations were admitted Licentiates in Midwifery, at a meeting of the Board on the 1st inst. :—

Butler, Wm. Harris, Old Charlton, Kent; diploma of Membership dated July 25th, 1865.

Cresswell, Richard, Lewisham, Kent; May 10th, 1866.

Edmonds, Chas. George, Southampton-street, Canberwell; May 9th, 1866.

Folkes, William, Dukinfield; May 9th, 1860.

Hay, Thomas Bell, L.S.A., Caledonian-road; July 25th, 1866.

John, William, Haverfordwest; April 26th, 1866.

Loane, Joseph, Dock-street, Whitechapel; May 8th, 1866.

Macdonald, John, Kilderminster; L.R.C.S.E., August 6th, 1858, and L.R.C.P.E., October 4th, 1864 (not a member).

Monckton, William, Brencley, near Tonbridge; April 26th, 1866.

Moore, George, Birmingham; July 24th, 1866.

Pryce, Richard Matthews, L.S.A., Caersws, Montgomeryshire; July 26th, 1866.

Quick, John, Penzance; May 8th, 1866.

Robinson, Richard Holt, Manchester; May 10th, 1866.

Spencer, George Othwaite, Upper Gordon-street; April 26th, 1865.

Wey, William John, Plymouth; May 7th, 1863.

The following gentlemen, having undergone the necessary examinations, received their diplomas in Dental Surgery at a meeting of the Board of Examiners on the 2nd inst. :—

Apperly, Ebenezer, Stroud, Gloucestershire.

Bartlett, William Penny, Kensington-park-terrace.

Harding, Thomas Henry G., Park-square, Regent's-park.

Lanc, Edwin Frederick, Bedford-place, Russell-square.

McAdam, George C., Hereford.

Oliver, John Cardell, Cardiff.

Read, Thomas, Holles-street, Cavendish-square.

Tracy, Nathaniel, Ipswich.

West, Edward Byatt, New Broad-street.

Williams, William Caleb, North Petherton, Somerset.

APOTHECARIES' HALL.---The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 2nd inst. :—

Argent, Samuel, South Molton-street, W.

Charlton, Alfred, Tonbridge.

De la Cour, George Francis, Chatham.

Folkes, William, Dukinfield.

The following gentlemen also on the same day passed their first examination :—

Burroughs, Thos. John, Guy's Hospital.

Davies, Wm. Richd., University College Hospital.

Dukes, Clement, St. Thomas's Hospital.

M. SIMONIN writes to the French Academy of Sciences to confirm a statement made by M. Maland, that he had discovered gold deposits in the department of the Marne. M. Simonin adds that he has found gold on the other side of the Cevennes, whence, he thinks, the ancient Gauls drew all their supplies of the precious metal.

RECENT letters from New Zealand allude to considerable deposits of bismuth in combination with copper, and state that an economical method of separating the metals has been devised by some one interested in the discovery.

FROM the Cape the news of considerable discoveries of gold is confirmed in the latest advices.

It is reported that the Prussian troops stationed near Brunn are sorely afflicted with cholera and typhus.

## Notices to Correspondents.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Can an L.K.Q.C.P.I. style himself M.D.Surg. on his hall-door, and, if illegal, would an action lie against him or any other individual for giving M.D. to a person?—for example, in a newspaper, &c., who might not be entitled to same?—Yours, &c., L.R.C.S.I.

He cannot *legally*, and therefore should not style himself M.D., unless he be a graduated Doctor in Physic. We are not aware that any ground of action would lie against one who might address an unqualified person as M.D.—Ed.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly answer the following questions in your next issue:—The Master of the Rolls in Ireland having decided that the L.K.Q.C.P.I. can use the prefix of Dr., and the College of Physicians Ireland, state that they admit to the "licentiate and doctorate of medicine," can the licentiate style himself M.D., L.K.Q.C.P.I.?

Is the holder of the above licence, possessing a surgical diploma, qualified to hold a poor-law or other appointment as if he were a L.S.A.!?—Yours obediently, BIRMINGHAM.

Is our Correspondent sure that the Master of the Rolls decided as he says? The form of license now given by the Irish College of Physicians does not give the expression "Doctorate of Medicine." Our Correspondent refers to the form in use shortly before the legal decision above quoted. The College interpretation of the prefix "Dr." will be found on page 18 of the Register of 1866. A Licentiate cannot style himself M.D.; but if he be also qualified in Surgery and Midwifery, and if he be 23 years of age, he can hold any poor-law appointment in Ireland; and, as a physician, he can hold any other appointment which "a duly-qualified physician" may hold in the Queen's dominions. Exceptional legislation may, in some cases, provide that the holder of a given place must be L.S.A. In such a case, of course, nothing but L.S.A. will do; but this cuts both ways: for example, no one can be physician to an Irish County Infirmary except he be a Licentiate of the Irish College of Physicians. See Register, above noted, page 12. We recommend our Correspondent to get this book from Messrs. Hodges and Smith, Dublin.

*The Hospital for Consumption, Brompton.*—The notice is inserted.

*Neophyte.*—Carbolic acid or phenic acid is one of the products of the distillation of coal-tar, and is somewhat analogous in its properties to creasote. It has considerable antiseptic powers, and is now being employed rather largely, both externally and internally, in the treatment of cholera.

*Inquirer.*—The name of the person mentioned does not appear in the present volume of the Medical Directory.

*Mr. J. B.*—Valerianic acid is prepared for medical purposes from fousel oil, which is one of the amyl compounds.

## Appointments.

- DR. JENNER, F.R.S., has been appointed Consulting Physician to the Hospital for Diseases of the Throat, vice Dr. Babington, deceased.
- J. C. BROWNE, M.D., M.R.C.S.E., Medical Superintendent of the Newcastle-on-Tyne Borough Lunatic Asylum, has been elected Medical Superintendent and Director of the West Riding of Yorkshire Lunatic Asylum at Wakefield, vice J. D. Heaton, Esq., appointed Commissioner in Lunacy.
- A. COLEMAN, M.R.C.S., L.D.S., &c., has been appointed Lecturer on Dental Surgery at St. Bartholomew's Hospital.
- R. HODDLEY, M.D., has been elected Assistant House-Surgeon to the Halifax Infirmary, vice J. McC. McWilliams, promoted House-Surgeon.
- F. W. LOWNDES, M.R.C.S.E., has been appointed Resident Surgeon to the Birmingham and Midland Counties Lying-in Hospital and Dispensary for Diseases of Women and Children, vice A. Veitch, M.D., resigned.
- DR. M. MACKENZIE has been appointed co-Lecturer on Physiology at the London Hospital.
- J. G. MACKINLAY, L.R.C.P.L., M.R.C.S.E., late Resident Medical Officer to the Charing-cross Hospital, has been elected Medical Officer to the Brentford Union Infirmary and the District of Isleworth and Brentford, vice J. Mackinlay, M.D., deceased.
- J. McC. McWILLIAMS, M.R.C.S.E., has been appointed House-Surgeon to the Halifax Infirmary, vice Mr. T. J. Pawcitt, resigned.
- S. PARKER, M.R.C.S.E., Surgeon to the Sheffield Public Hospital and Dispensary, has been appointed Surgeon to the Sheffield General Infirmary.
- W. WIGHTMAN, M.D., has been appointed Physician to the Halifax Infirmary, vice M. S. Kenny, M.D. deceased.
- MR. R. ALLEN has been appointed Medical Officer for the Towcester District and the Workhouse of the Towcester Union, Northamptonshire, vice T. Collier, M.R.C.S.E., resigned.
- T. H. BARNES, M.D., has been appointed House-Surgeon to the Loughborough Dispensary, vice A. Jones, M.R.C.S.E., resigned.
- E. H. BIRKENHEAD, D.Sc. Lond., has been appointed Lecturer on Chemistry at the Liverpool Royal Infirmary School of Medicine.
- G. N. COLLYNS, M.R.C.S.E., has been appointed Medical Officer for the

- Tedburn St. Mary District of St. Thomas's Union, Devon, vice J. A. Edwards, M.R.C.S.E., resigned.
- B. ARCHDECKER DUNCAN, L.R.C.P.Ed., of Gower-street, Bedford-square, has been elected a Fellow of the Royal Society of Literature.
- H. B. MARSH, L.R.C.P.Ed., has been appointed Medical Officer for District No. 3 of the Upton-on-Severn Union.
- W. MATTERSON, M.D., has been appointed Physician to the York County Hospital, vice W. E. Swaine, M.D., resigned.
- C. A. NEWNAM, M.R.C.S.E., has been elected Surgeon to the South Staffordshire General Hospital and Wolverhampton Dispensary, vice F. A. Nesbitt, F.R.C.S.E., deceased.
- W. S. SAUNDERS, M.D., has been elected Medical Officer of Health for the City of London Union.
- W. J. TATTERSALL, M.R.C.S.E., has been appointed Physicians' Assistant at the Royal Infirmary and Dispensary, Manchester, vice T. Leads, M.R.C.S.E., resigned.
- W. THOMSON, M.D., has been appointed Medical Officer for the Annahilt Dispensary-District of the Lisburn Union, county Antrim, vice W. Rutherford, C.M.Glas., deceased.

## BOOKS RECEIVED.

- On the Rational Employment of Mercury in the Treatment of Syphilis. By Dr. Coloniate Meredyth. Hardwicke.
- Cholera Non-Contagious. By Edwin Hearne, M.B. Southampton: Gutch.
- The Antidotal Treatment of the Epidemic Cholera. By John Parkin, M.D. London: Churchill and Sons.
- On Epidemic Diarrhoea and Cholera. By George Johnson. London: Robert Hardwicke.
- Search by \_\_\_\_\_ London: Booth.
- The New York Medical Journal. Vol. iii.
- Army Hygiene. By Charles Alexander Gordon, M.D. London: John Churchill and Sons.
- Wine as it should be. By James L. Denman, Piccadilly. Free on application.

## Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

### BIRTHS.

- On the 12th ult., at Rathmines, the wife of W. H. Cruice, Surgeon R.N., of a son.
- On the 20th ult., at Clifton, Bristol, the wife of Dr. Martyn, of a son.
- On the 26th ult., at Stickney, Boston, Lincolnshire, the wife of P. Maxwell, M.D., &c., of a daughter.
- On the 27th ult., at the City of London Lunatic Asylum, Stone, near Dartford, the wife of Octavius Jepson, M.D., of a daughter.
- On the 30th of June, at Tranquil House, Morro Velho, Brazil, the wife of John McIntyre, M.B., M.C., of a daughter.
- On the 1st ult., at Colaba, Bombay, the wife of John Reynolds, M.D., L.R.C.P., &c., of a son.
- On the 25th ult., at York-road, Lambeth, the wife of F. Blackman, M.R.C.S.E., of a son.
- On the 26th ult., at Stickney, near Boston, Lincolnshire, the wife of Peter Maxwell, M.D., of a daughter.
- On the 29th ult., at Iver, the wife of W. W. Leadam, M.D., of a daughter.
- On the 5th inst., at Ardee, county Louth, the wife of Thos. Jas. Moore, M.D., of a daughter.
- On the 7th inst., at Edgbaston, Birmingham, the wife of B. W. Foster, M.D., of a son.

### MARRIAGES.

- On the 24th ult., at Stapleford, Cambridge, Richard Edwin Ruffe, M.R.C.S., L.S.A., of Bingley, Yorkshire, to Lucy, youngest daughter of W. Baker, Esq., of Stapleford.
- On the 26th ult., at the Parish Church, Snettisham, Norfolk, Hutchins Williams, M.R.C.S.E., L.R.C.P.Ed., &c., Surgeon Peninsular and Oriental Company's Service, son of the late Hutchins T. Williams, Esq., of Dublin, to Ellen Harriet, daughter of the Rev. John Colclough, M.A., Vicar of Snettisham.
- On the 2nd inst., at St. Stephen's Church, Dublin, George Cochet Chesnaye, F.R.C.S.I., L.K.Q.C.P.I., H.M.'s Bengal Medical Staff, to Mary, daughter of Robert Roberts, Esq., Chief Transfer Officer, Bank of Ireland, Dublin.
- On the 2nd inst., at Freshwater Church, Isle of Wight, George Ralph Tate, M.D., Assistant-Surgeon, Royal Artillery, to Sophia, eldest daughter of David Way, Esq., of Afton, Isle of Wight.
- On the 7th inst., at Lansdowne-crecent, Glasgow, Edward Turner Smith, Esq., eldest son of J. Fairfull Smith, Esq., W.S., to Margaret Eleanor, elder daughter of the late Peter Fullarton Watt, M.D., of Demerara.

### DEATHS.

- On the 19th ult., G. Walker Skinner, M.R.C.S.E., of Sheffield, aged 25.
- On the 20th ult., at Crawford Villa, Spring-grove, Denis Cronin, M.D., late of Bruton-street, Berkeley-square, aged 59.
- On the 20th ult., Chas. Otter Gilby, M.R.C.S.E., of Brewood, Staffordshire, aged 46.
- On the 23rd ult., Dr. Frederick Drought, of Richmond, Fairview, Dublin, aged 78.
- On the 23rd ult., Edward Young, M.R.C.S.Eng., late of Highbury-grange, formerly in the H.E.I.Co.'s service, aged 52.
- On the 27th ult., at Queen-street, Cheapside, the wife of Wm. Clapton, F.R.C.S.E., of a daughter.
- On the 29th ult., at Montagu-square, the wife of R. E. Dudgeon, M.D., of a daughter.
- On the 24th of May, at Strathalbyn, South Australia, Dr. Sinclair Blue, late of Bridgton, Glasgow.
- On the 27th ult., at Paris, Charles Higgins, M.D., Knight of the Legion of Honour, aged 60.

ERRATA.—In Dr. Travers' paper on "Poisoned Blood," page 162, line 7, supply "gout"; line 15, for "qui," read "que;" line 53, for "l'a," read "c'a;" for "pour," read "par."

"SALUS POPULI SUPREMA LEX."

### THE ADDRESS IN SURGERY.

DELIVERED AT THE ANNUAL MEETING OF THE BRITISH  
MEDICAL ASSOCIATION,

*Held at Chester,*

ON THURSDAY, AUGUST 9TH, 1866.

By WILLIAM BOWMAN, Esq., F.R.S.

MR. PRESIDENT AND GENTLEMEN,—Surgery has always been that department of the Healing Art which most strikes the imagination of mankind, and secures their admiration, by prompt, dexterous interposition, in obvious and great perils, where life or limb is jeopardised, when the ignorant or timid are ready to despair, or the disease seems too terrible and deadly to be controlled. One now steps in, holding in his hand the talismanic charm of knowledge, with skill to find and courage to touch, for their correction, the hidden springs of life, and in a few moments how altered is the scene. The poor sufferer, a weeping family, or, it may be, a nation in deep anxiety, is relieved; and gratitude, the most precious human tribute for so great a benefit, so opportunely conferred, mingles with the respect and almost veneration that greet the successful operator.

Pardon me, if I avow, arrived at middle age, that my boyish ambition—not far from this *Castrum* of the old Romans, and under the inspiration partly of one still among us (my father's friend), partly of others to whom I am even more deeply beholden—was to be a great surgeon. And though I am able thankfully to acknowledge a gradual diversion of my lot in life away from this dream of earlier days, I yield to none in my regard for the eminent dignity of the surgical art, concerned, as it is, with some of the dearest earthly interests of mankind and certain to rise more and more in their esteem as they become more capable of weighing things and men by the true and real standard of *their usefulness*. For I see no reason to doubt that future ages will still accept the pious saying of one of old, that surgery is the hands of God: the human hands, apt images and reflex of man's whole being, from his morning hour of puling helplessness, when the

"Tender palm is prest  
Against the circle of the breast;"

through all his working day of time; until they at last shall be upraised once more in joy and adoration, to hail a brighter and an eternal dawning; the human hands permitted now through insight into God's laws, to be the saving instruments of that earthly life and organization, which His power, wisdom, love, having first brought into being, still alone both sustain and cause to perish when their part is played; of that organization which dies every hour it lives, which indeed dies by living and lives by dying, and which wondrously transmits ever its own prerogatives and dark secrets to a succeeding life, destined apparently to remain a marvel and a mystery impenetrable to all generations.

A general survey of the present state of the Healing Art in those countries that most represent the recent progress of mankind, may well incline us, on an occasion such as this, to outstep the narrow limits of the specialty of surgery, to which, indeed, our precedents do not confine us, and to inquire whether we be not in some danger in England now, amid the multitudinous divergencies and details of modern practice, of losing sight, in some measure, of the essential unity that pervades our whole work of healing in the world; and further, whether we do not

need to hold more to this central idea of unity, in order, by greater concentration of our powers and agencies for good, more effectually to promote the proper objects of our great profession, by better directed common efforts than in times past.

And can such a theme be more appropriately handled than before an Association which is, up to the present moment, the only visible upholder and representative of the comprehensive unity of all ranks and degrees of healers in this country, and which has been for many years working towards the realization of it.

Let us, then, spend a short time in tracing, if we can, the scope and meaning of this work of ours, which interests ourselves so very closely, and our fellow-men hardly less. And for this purpose our past history shall first be adverted to, so that we may gain, as from a distance, a more general and a juster view of our whole position.

With the earlier developments of the art in remote ages we are little concerned, except to observe that the same simplicity of conception which we now find among our less instructed countrymen, implied in their respectful customary epithet of "doctor" addressed to us all alike, regardless happily of university-acquired titles of too motley import and of modern Acts of Parliament—this same simplicity of conception would probably more apply to the healers of a dawning civilization, who, though they then, as now, must have failed in any instance to embrace all knowledge and all the powers of treatment, yet could hardly have been other at first than general practitioners.

Probably the state of the healing art (if so it can be called) in various savage tribes, and among the antique and decrepit communities of the East, only now being awakened out of the torpor of tens, perhaps of hundreds, of centuries, by the rude shock of contact with modern European forces, may exhibit to us, not inaptly, what it once was among ourselves. Certainly the early growth and moulds of our profession must have been natural, not fostered by artificial means; except indeed where the policy of chiefs, or the craft of a pagan priesthood, may have warped them to their purposes. But generally, where individuals evinced or professed an aptitude, opportunities of experience would be rife enough; and according to the nature and variety of these would be the developments of knowledge and the divisions of practice.

In later ages the elaborate civilization of the Greeks and Romans, and subsequently of the Arabians, was manifested scarcely less in their knowledge of healing than of other useful arts, as their extant writings attest; it being reserved, however, undeniably for Christianity to elicit first among mankind the true spirit, as well as the right exercise of the art, in the institution of hospitals and asylums, and of nursing brotherhoods and sisterhoods for the sick and maimed.

But indeed, although the practice of surgery in particular must have reflected, like other arts, the prevalent temper and ideas of those times, and may have been often rude, coarse, and indiscriminating, based on loose surmises, false analogies, or on prejudices or fancies altogether absurd, hence becoming what we might now be inclined to call unfeeling, even cruel; yet always, its aim being, beneficent, its tendencies must have been so too—a humanizing art, intervening on the side of mercy and pity, even in the wildest hours of savagery or war.

Turning to Britain and the dark ages, haply our chirourgeons were a sorry set, who carried out lamely the despised manual part of treatment, under the direction of an order of men, by priestly office or by education and social rank, above them, to whose authority they bowed; a set of men misnamed learned, ready in every difficulty to quote Galen without understanding him, and generally more ignorant than the poor handicraftsmen they controlled; men whose word could seldom be questioned, never gainsaid, though from the falseness of their principles, they could never advance one step in true knowledge.

It was probably war, ever recurring war, that raised a few individuals from time to time into greater prominence

and credit as surgeons; for the powerful leaders of armies must have often experienced the benefits of surgical treatment, and in extremities of danger the surgeon must needs have taken a position in the esteem of multitudes which those would miss who could not, or would not, staunch a wound or save a life by operation. And it is inconceivable that, even in those half barbarous times, the greater sort of minds among the body chirourgeons of emperors and kings should not have emancipated themselves from the obviously absurd relationship implied in their being merely the manual executors of the dictates of other men, whose fantastic pedantry and real ignorance of the practical part they must necessarily have contemned.

And in civil life a counterpart was seen. Isolated students in convents, cullers of simples, ignorant travelling quacks and mountebanks, bone-setters and leeches, flitting formless creatures in the twilight time. Then came the guild of herbalists and barber-surgeons. Then from our universities, especially on the revival of learning, physicians, with a truer scholarship and more open minds, to whom all mankind must ever acknowledge themselves indebted—men competent to hold their place, even in that age of crudition, with the most exalted dignitaries in Church and State, and still maintaining, probably on that very account, their old superiority in station over their less learned chirourgical brethren.

But now here and there a real surgeon rose; bold, perhaps prurient also; successful in grand ventures; starting the popular imagination by some marvellous cures of deep painful disorders or of portentous aspect till then deemed incurable. Thus operative surgery in great cities became the surgery of the greatest practitioners, and oftentimes overtopped and overshadowed the reputation of learned *medici*, causing no doubt jealousies, which we know to have been keen, but which we may now all the more afford to smile at, as we are certain none such exist amongst ourselves. Surgery thus became studied more and more by a class, as its prizes were great, and some men seemed by tastes and natural gifts more fitted to shine in it. It became an elaborated art, founded on observation of anatomical relations, both healthy and morbid. It began to have a distinct literature, and a body of rules and precepts, which were the subject of public debate, and were traditionally transmitted. Its professors increased in numbers and breadth of aim; they even shared with the most skilful physicians in cultivating the knowledges (hardly sciences as yet) which pertain to the healing art; and, to draw nearer to our own day, they have within the last hundred years, in this as well as in all civilized countries, borne an equal, in some instances a transcendent share in enriching and extending the whole field of medicine.

But I am not here, gentlemen, to say flattering things of one department of our art to the disparagement of another. Nothing could be more remote from my intention. On the contrary, I desire to speak the truth only; to show our common aims and victories, and to vindicate the common bond that unites us all.

And for this, I must still ask you to revert with me for a moment to the Tudor times.

We are tolerably well acquainted with the state of practice in our own metropolis in that day, when some of the most eminent revivers of learning, of whom England is rightly proud (though some of them were favourites of a court paid by Church sinecures), established an institution, since become venerable, which in those days fought a hard, and, it must be added, a successful battle with the surgeons before the Lord Mayor of London and other of the Queen's delegates (the more enlightened Master of the Rolls and the Bishop of the diocese bringing, we are told, many imposing arguments on the surgeons' part) for the right and privilege of alone prescribing in surgical cases inward medicines (and such medicines!); when the apothecaries' shops, no less than the chirourgeons' instruments, were still to a large extent under their control; and when, for example, one unhappy John Luke, *ocularis medicus*, receiving a faculty to treat diseases of the eye, was strictly

limited to the use of external means, and forbidden all internal remedies, by whatever avenue they might be introduced, except under the advice of some learned and experienced physician accredited by the College.

All these grave and learned men played their part well, however, according to their light. They upheld amongst the highest and most cultivated of the land, as we gladly acknowledge their successors do at this day, the dignity of the profession and pursuit of healing. And if they did not plant this dignity in its true seat, knowledge of the frame that is most noble on this earth, and knowledge for the sake of usefulness to suffering man; if they sometimes stifled thought, as when they caused one of their number to recant, who had had the temerity to maintain that Galen was capable of error; we may remember what they did to introduce anatomy into England and to advance surgery itself. Receiving from Lord Lumley an endowment under the great seal for a surgery lecture in the College, they "most thankfully accepted so honourable and generous a donation, and built rooms more ample and spacious for the better celebration of this most solemn lecture." And from amongst them sprang one, whose well-known services to our common calling and to mankind can never be adequately honoured, particularly for the prescient, penetrating, comprehensive character of his intellect, and the clearness of his perceptions—whose name will descend to the latest posterity amongst the greatest of English worthies.

William Harvey was Professor of Anatomy and of *Chirurgery* to the College of *Physicians*. His character was every way grand. The main feature of it was a supreme love of truth, and an intense longing to penetrate the secrets of organic nature; and for this he asserts always the right and the duty of going straight to the fountain-head of nature herself, acknowledging no master in things natural, but facts and the evidence of the senses. Modest, gentle, unselfish, courteous, not covetous of honours, he was fearless in asserting new truths, believing in their own native power to live and fructify; slow to controvert errors, knowing that they would disperse of themselves, and that narrow and prejudiced minds would cease to cavil when the clearer light should have time to blaze forth. Withal he had that deep reverence for the Author of Nature which springs unbidden from the contemplation of man's own littleness amid works so mighty and so minute. How profound a truth he beautifully proclaims when he says: "If you will enter with Heraclitus in Aristotle into a workhouse (for so I will call it) for inspection of viler creatures, come hither, for the immortal gods are here likewise, and the Great and Almighty Father is sometimes most conspicuous in the least and most inconsiderable of His creatures!"

The torch of Harvey was lighted in Italy, where, while the fine arts were already waning rapidly, Science was rearing erect her standard; and at Padua, where he listened to the teaching of the greatest masters of anatomy, medicine, and surgery—Fabricius ab Acquapendente, Minadus, and Casserius,—he must, doubtless, have discoursed with, and caught the spirit of, one still greater—Galileo. At home he may probably have known personally, certainly by his works, the immortal author of the "Advancement of Learning." Thus is Science exhibited as not of a country, but of the world.

But tracing onwards the progress of the healing art in England, which had been founded at first on the institutions, traditions, and customs which, we shall find, represented the convenience of an imperfect and transitional stage of society, not less than individual tastes, growing rigid under the influence of forms and titles, and gathering around themselves clustering personal and corporate interests, not always in harmony with those higher objects by which alone they could have been at first justified; and tending to keep apart, though with decreasing force, the two great bands of a common profession.

The physicians, it must, I think, be said on the whole, though with some remarkable exceptions, receded during

the last century from the spirit and the traditions of Harvey, while they maintained orations to his memory. It is not surprising that anatomy and surgery should have ceased to be actively promoted by a College which was gradually losing its hold on the surgical domain of practice in proportion as surgeons were becoming independent of the old restraint.

The physicians were now, by their abstinence from all manipulative treatment, in a position of increasing isolation as regards a great domain of the field of experience. They were specialists by a great defect—by a self-negation; and the consequence was that many of the higher intellects amongst them betook themselves to a too exclusive clinical observation of disease, analogous to that of some of the ancients, and not sufficiently seconded by deep and personal study of the organic structure, and the laws of life; while others distinguished themselves by learned or philosophical labours, more or less important, and more or less connected with the immediate work of their calling.

The result has been, that the medical world has seen several systems or schemes of treatment promulgated on insufficient bases, but with much pretension of a simplicity for which nature no gives warrant, and which have yielded one after another at the first summons of reason and common sense; not without grave discrediting of the whole profession in the public eye, and not without giving a sort of countenance to that easiness of belief with which, within our own century, have been received by the public the flimsy follies of the shallowest and barrenest, the most credulous and the most boastful of medical phantom sects, that of the self-styled homœopaths. In the more recent times, however, of John Richard Farre, of Matthew Baillie, and of Richard Bright, they have laboured afresh in the patient study of disease, not only during life, but have themselves, with their own hands and scalpels, sought real knowledge by the personal examination of the organs after death. They have also taken a large and important share in advancing the physical, chemical, and physiological sciences; in these and other ways thus setting a splendid example, and redeeming a position which might otherwise have been jeopardised.

For the surgeons had approved themselves the truer followers of Harvey. Holding always to Anatomy, as by the very nature of their function they found themselves more and more constrained to do, and also finding apter materials for study in the more exposed and less recondite diseases, falling to their care, as well as in the open results of wounds, including those of their own making, they have joined Anatomy, Pathology, and Surgery in a natural alliance, most favourable to progress, and always abounding in new fruits, and have gradually risen in influence; establishing in our great hospitals, and in our fleets and armies, an equality of rank with their more crude, but (must we say it, in all kindness?) unhandy brethren; and unostentatiously but surely asserting more and more the claim of the surgeon's hand to be guided by the surgeon's mind and conscience, from which, henceforth, it can never again be unholy divorced.

In the last century, in our own country, two men stand out from the rest—two Scotchmen—who gave a great impulse to the healing art. Brothers by blood, the Hunters were also of like tastes and industry, and nearly of equal genius, though John excelled by the acuteness of his penetration and the universality of his views. Both, when young, were surgeons and anatomists, toiling in Harvey's "workhouse," and William acquired his fame in practice as an accoucheur. Both were illustrious by the museums they created, one of which has since become, by State purchase and the subsequent labours of Richard Owen, indeed of more than one kindred mind, supported by the liberal subsidies of the College of Surgeons, the most glorious apanage of a great profession that the world has yet seen; and the other is in the city of Glasgow, to which the munificence of its founder bequeathed it, with an endowment for its maintenance.

John Hunter was so largely employed during many years in applying his knowledge to the relief of human ills, that it is indeed marvellous how he could have at the same time laboured so hard in the general field of the sciences of life. But (given his mental capacity, zeal for his subject, and the pauseless industry that sprang from that zeal, and overbore the instincts which must have often yearned for repose in a life of great anxiety and suffering) this double labour, which since the time of Harvey had hardly been seen united in any one man, is to be explained by the mode in which his mind ever carried physiological principles into the details of daily practice, and sought in return, by the study of those details, to illustrate and advance his general views of the processes of life. Had the two fields of thought been in his estimation distinct and separate, he could not have achieved in each so great a victory; in each, it will be found on examination, his success depended largely on the real union which he, more than any of his contemporaries, or even of his predecessors, recognized to exist between them. English surgery and English medicine, in all their departments, have been since strongly coloured by this principle. This indeed is the abiding lesson which his life and labours have imparted to those who succeed him in the noble function of ministering to the wounded and sick in his own country and throughout the world.

The Hunters may both be regarded as types of what the great masters and leaders of the healing art should be. They were anatomists; they were physiologists; they were pathologists; not by secondhand learning from the tongues or pens of other men, though this they did not despise, but by truth-loving observation and interrogation of Nature herself, in all her haunts of health and of disease; admitting no veils of limitation to be drawn by fashion, or caprice, or selfish interests between provinces and things essentially akin, but taking in the whole scope of the art as one great and ample field of noble study and beneficent activity—one by the unity of man's body, to which it yields a voluntary and loving service; one by the identity of the methods of research by which the secrets of that body (whatever secrets, and of whatever part) are to be disclosed; one by the common aim and intention of all treatment, internal or external, remedial or preventive; one, lastly, by the simplicity of the moral attitude which should stamp us all as members of one body, in our relations towards one another, to individual patients, and to the community among which we labour.

Gentlemen, I look upon the present meeting, comprising native members of every branch of our profession (and would that we could welcome, in future years, many more brother members from other lands), as one representing the idea most needing to be insisted on amongst "doctors" at this time and in our own country, and which, I am persuaded, men like Harvey and the Hunters would have been foremost to assert and act upon—the idea of the *oneness of our common calling*. And can we aver that there is no need to advance this idea? For, could we imagine these great ones of the past to be still with us, what special encouragement or opportunities for his cherished pursuits, we may ask, would Harvey now find in his own favoured College of Physicians?—whose welfare and improvement, we are told, "was the chief object that occupied his mind for several years before his death," but where "solemn lectures" on surgery are no longer given—where there is no anatomical or surgical work performed, and where no "repository for simples and varieties" exists, such as he fondly hoped by his benefactions and his example to have founded; even no museum of morbid anatomy, such as Baillie and Bright would have longed for. On the other hand, should we be likely to find Harvey, a Fellow of the College of Physicians, admitted to demonstrate the motion of the heart and blood in the Hunterian theatre? Could William Hunter, having become, as he did at the age of thirty-eight, a licentiate of the College of Physicians, and not being longer "in actual *bona fide* practice as a surgeon," share in the

councils of the Hunterian College, or in the love-labour of its museum—or could he adorn its chair by his eloquence? Finally, could his greater brother, immortal by his "Treatise on the Blood," but being "only a surgeon," find entrance, consistently with existing usage, to discourse on that great theme within the walls which derive their chief glory from the discoverer of the circulation of the blood.

It would ill become me, humble as I am, and feeble in grasp of thought, to utter or imply anything in the way of censure of these venerable corporations, which, with all their human imperfections, have done, are doing, so very much to adorn and advance each its own side of our common profession; and if neither of them has yet found itself at liberty to esteem of subordinate importance those class and college interests, those "rights and privileges," which a former age fenced in by forms of oath now generally disapproved of, whatever useful purposes they may once have served, it must be freely acknowledged that much has been effected by both in many ways, in recent years, to approximate to a policy more liberal and large, and certainly one more likely to secure the class interests themselves, by engaging for them, so far as they are good and useful, the support of the whole profession.

Some minds abler than my own may indeed doubt whether the time be yet fully come for any large attempt at consolidation or union of these and other kindred bodies. We may be deemed to be still in a transition period, in which we must be content to work a little here and there, as we may, towards a better organization and truer views. I know not. But I must express my own conviction that the old rivalries of "physicians" and "chirurgians" are now laid asleep in the breasts of all men of sense; or that, if they survive at all in our ampler day, it is only in some remnants of the traditional policy of the council-chambers of corporations, the vast majority of whose members are now too enlightened to harbour them much longer, against the broad and well-understood interests of a whole profession. I am persuaded that the leading minds of both the more powerful corporations are in accord with the great bulk of thoughtful medical men throughout the three kingdoms, that these great and noble foundations, so far as they retain in their constitution or in their forms traces of the antiquated prejudices and narrow notions of an age long since past, should mould themselves afresh to suit the wants of a more instructed time, when the medical world, being older and much larger in numbers, is also more highly educated and wiser than before. The whole professional body has a perfect right, most of all in our progressive England, to see the institutions which are its own made conformable to the wants of a period of unexampled social activity and advancement, when all the old impediments to intercourse are vanishing day by day as by the touches of an enchanter's wand, and when there are spread everywhere over the land able and intelligent members of our profession, whose co-operation should be invited and carefully organized, not only for the satisfaction of their own just wishes, but still more for the sake of the immense impulse that would thus be given to the prosecution of those common objects which it so much imports us, as a scientific and professional community, to pursue.

And here I trust it may not be out of place to call before us for a few moments the memory of four men, from whom, had they been spared to us, a comprehensive view of all interests, judicious counsels, and a liberal course of action, might have been expected. It cannot, indeed, be truthfully said that their loss is irreparable; for in England, no man, however valuable, can long be missed. Their room will doubtless be supplied; but to allude to the living might be invidious.

Benjamin Collins Brodie was eminently a man belonging to us all. A great surgeon, he was also a great physician, though probably he could not have been placed on the Register under that title. But he was a great medical surgeon, able to take in all the aspects of every complex case, to prescribe or withhold physic, to operate or to ad-

vise against operation. This capability arose primarily from what has been already suggested as its natural and legitimate source; he had zealously, as a young man, pursued the paths trodden by Hunter. He knew the body and its functions by the evidence of his own senses; he had meditated deeply on the inner phenomena of life; he had experimented on animals; he had enlarged the knowledge of his day. When the cares of an almost overwhelming practice pressed heavily upon him, he still did not desert science, and we owe to him, in addition to his many practical works, some most thoughtful contributions to physiological psychology. His scientific fame, reaching everywhere, is an honour to the medical profession—not alone to the surgeons, but to us all.

Joseph Henry Green was of too much capacity to be a surgeon only. Early devoted to metaphysical speculations, for which his grand and subtle intellect peculiarly fitted him, he was also a wise, prudent man of action. His views of our art were always extended and liberal. He embraced within his range all the world of life; he saw that *pure surgery*, so called, was a narrow and impossible specialty; he looked on disease as he found it in nature, not capable of classification by any such test as that of the applicability to it or otherwise of one special kind of treatment, the surgical or manual. This last was to him a noble portion, but a portion only, of the whole art. He was always anxious, like Brodie, to enlarge the basis of our profession, to elevate the standard of acquirement in its members, and to promote the sciences which belong to it.

I recall with gratitude the converse—in later years, the intimate and friendly intercourse—I enjoyed with both these considerable men. The third to whom allusion shall be made was in a nearer sense my loved and honoured friend and workfellow. Bred a surgeon as well as a physician, and always fond of surgical pursuits, a teacher of anatomy, a professor of physiology, and of general and morbid anatomy, an ardent worker in the physiological laboratory, mastering in a real and practical manner all the details of his subject, Robert Bentley Todd was both a voluminous writer himself, and a zealous promoter of literary and scientific work in other men. Then he became a clinical teacher and practical physician, indefatigable in the hospital wards, excelling some of his English contemporaries by the constant reference he was able to make in his teachings to anatomical and physiological facts and principles. Over-burdened with engagements of various kinds, he yet always strove earnestly to promote in his own college, as well as elsewhere, the study of his favourite sciences; and he delighted to speak of those distinguished men, the associates or early successors of Harvey, who had shed lustre on the college by their anatomical researches; particularly Francis Glisson, *omnium anatomicorum exactissimus*; Thomas Willis, the author of the still classical work, "Cerebri Anatomia;" and Clopton Havers, known chiefly by his "Observations on the Bones."

One who followed thus closely in the footsteps of Harvey and the later British anatomists, whose mind, too, was remarkably sagacious and practical, and whose character was of force to leave a considerable impress on his generation, could not have failed to take an active and useful part in promoting union amongst us. I venture to think that, as his brethren come to look from a little greater distance on his career, he will rise yet more in their estimation; and his friends will add their testimony to the excellence of his heart and life, as his name and fine countenance are revived in their memory by the marble statue erected in his honour in the hospital which he largely contributed to found.

You will anticipate me in the fourth name I would mention—that of Charles Hastings, so lately lost, so justly dear to the members of this Association. His great merit has been, that he first conceived a union of all the classes of our profession for common objects, and bore a principal part in advancing that union, under many discouragements.

ments, to the point we have already reached. I trust that his spirit of wisdom and conciliation, his large-heartedness, his breadth of view, will prevail in the counsels of our whole profession, and guide us all to a more complete concord of thought and action in whatever concerns the advancement of the objects he deemed so precious.

Let us now inquire, by glancing for a moment at one or two characteristics of the age in which we live, whether the time itself does not ask us to take a wide view of our calling, and to break through the trammels of a period of comparative immaturity. We see mankind everywhere becoming more and more *one family*, chiefly by the increase of man's dominion over Nature, through augmenting knowledge of her laws.

It is but a little while ago that Galvani and Volta, experimenting on harmless frogs, in the highest spirit of science, opened up new provinces of research, in which Davy, and Oersted, and Ampère, and Faraday, were soon to astonish the world by the rapidity and brilliancy of their discoveries. And it seems to me but yesterday—for I was there—that our Wheatstone, under the approving eyes of Daniell, passing the wire of his battery beneath the Thames, in presence of the now lamented Prince whom we had just welcomed to our shores as the Consort of our Queen, proved the possibility of the subaqueous transmission of those subtle vibrations, whose rate of travel we now know to exceed in a very high degree that of the mandates of the will along the nerves. Yet already, by a combination of enterprise and skill unparalleled, the magic twine unites two continents; and man's thoughts, cyphered with unerring truth by silent-speaking symbols, in the last degree refined, and borne onwards by tender tremors of the metal, fainter yet farfleeter than Æolian whisperings, are traversing every moment—even as I speak—the awful solitudes of Atlantic depths, under miles of ambient water; where no sound, hardly light itself, can ever penetrate: all heedless of the fogs and icebergs and mimic storms of the surface, 15,000 feet above. And soon the globe itself will be woven over with a time-annihilating network;—a blessed harbinger, as well as sure eventual promoter of goodwill and peace, of peace and goodwill to all mankind; and certainly a fulfilment, of which we none of us as yet appreciate the full meaning, of the loving purposes towards our race of the eternal and infinite God.

From the bed of these watery deeps, too, abysses no longer unfathomable, the finger of man has picked up evidences of teeming life *there also*, such, probably as he now knows to have built up, by slow and gradual accumulation, in geological ages of unassignable remoteness, strata of the earth's now solid crust, tens of thousands of feet in thickness; and these in their turn contain the fragmentary but faithful records of series of organisms that have preceded the existing forms; and which seem to intimate, with other collateral proofs (though I prejudice nothing), that life has been *continuous* on our planet from the first origin of organic being, through successive *generative* links of evolution, even down to, and into, the very times in which we live.

Again: while we consider all this, and descry through Harvey's "optick glass" of higher power, in the tiny elements of the gland of the insect or the gigantic quadruped, an identity of essential structure with the corresponding parts of our own frame; and while we call to mind that when our yet uncharactered members were seen already by the All-Seeing, every one of us consisted wholly and merely of such tiny elements of structure, who shall say that the touch, the very touch of a mysterious organic kinship, is not there, though it be as yet untraceable with certainty—as yet unprovable? The pedigree of man himself seems to be on trial before the Court of Science; and a true verdict may be given at no distant period. Let whoever loves Truth, and the God of Truth, await it with perfect calmness, though it should possibly fail to coincide with some prejudices of the timid. I may incidentally express an earnest hope that our profession, which beyond

others is brought to the threshold of such questions by the nature of its studies and by its habits of thought, and which I aver to be signally remarkable for its love of truth and regard for religion, notwithstanding some vulgar echoes of old charges against us, will play a useful and moderating part by reassuring less informed persons and quelling groundless alarms. Let us cast aside the foolish thought so flattering to our pride, that man's dignity depends in any the least degree on the mode of origin of his material organization, whether in the individual or the race, any more than for the structure of his mature material organs; and not rather on that capacity for the reception of the Divine Spirit, and for elevated commune with God and His works, which comes with growth, but with which, at the earlier moments of his origin, he has not yet been endowed. It may come to be worth considering, that man's nature may derive comfort from an inversion of the dictum of the witty orator of the Sheldonian Theatre; and that it may be a nobler, even a more Christian and a less Pagan view of our destiny, to find ourselves belonging from the first, in the Divine counsels, to an ascending rather than to a descending series of the scale of being. We may come to acknowledge by Science, as we now accept by Revelation, that our bodily organization has sprung in the past from the dust of the ground, though only through ascending forms; and as to our hereafter, although we know not yet what we shall be, we have the assurance that we shall one day share the angelic nature in seeing God as he is.

Would that the divines of England, and their venerated leaders, under the difficulties of their position, could be always mindful, not in words only, of the nobler principles so congenial to this spirit of her church, that such questions, so far as they belong to the domain of man's intellect and sense, must and will be followed up according to the laws of his being and the onward current of human thought, in the interest of truth only, regardless of all consequences! Would that they would all have faith in science—that they would meet her, embrace her, and not mistrust her, being firmly convinced that her true results, when well proven and finally accepted by all competent minds, after full inquiry, become, so to say, *vox Dei!* That they would remember that such a voice may be so potent as to rise to the height of that which once summoned an apostle to cast off his most rooted prejudices, and to exclaim, "What was I that I could withstand God?" Without in any degree prejudging pending questions, it must surely be prudent, in the interests of both truth and religion, to hold an even mind; not yielding to unworthy fears of the divine faculty of reason, nor abusing those who are honestly employing it within the sphere of its proper activity; but having a faith, above fear, in the certain victory that awaits both reason and religion—both God's precious gifts to man in his darkness, and both certain to harmonize at length in Him.

Turning now to touch lightly on some of the advances of medical science in recent days, let us remark how inseparably they blend with, and mutually illustrate, the general progress outside our own immediate province. They may be conveniently comprised in two words—*scientific insight* into our work of healing: the actual conditions of the body, in health or unsoundness, having become more easily distinguishable; their mutual play and connexions better understood; and our means of profitable interference at once more numerous, more definite, and more manageable.

Before a Society so completely informed as you are, gentlemen, I feel it unnecessary to attempt to make good this part of my programme by laboured arguments or lengthy illustrations; examples are only too abounding. Harvey had heard the healthy sounds of the heart; but its morbid sounds inform us now of the nature of its structural defects. The sounds of breathing must countless times ere this have met the ear; but it was reserved for our own days to study them so as often to enable every tyro to say what is the state of those great organs, hidden

from our view, but so indispensable to life. And so with percussion. Nay, with our eyes we can now behold, for the first time in its living acts, that marvellous mechanism in its most exquisite and joy-inspiring movements, as well as when it is oppressed by disease, which stands as a sentinel at the orifice of the air-passages and on which the voice and speech primarily depend. And need I advert to other applications of optical mechanism, or recount how one has called forth another, until the various internal surfaces and structures, particularly those of the organ of sight itself, are now opened to hourly survey, to scrutiny most exact and delicate, so that often even the pulsation of the smallest arteries or veins and the physical conditions of the capillary bloodvessels, with almost the earliest and slightest signs of morbid change, may be detected and made available as guides to treatment? Much might be said under this head. Diseased states thus submitted to the faithful eyesight are seized on by the mind with a vividness that is of inestimable value to the practitioner in framing his conclusions as to treatment; and he can judge too, by the direct evidence of sense, how far to continue to follow up these. In a word, all the advantage the surgeon has hitherto had over him who deals with concealed diseases, in that he has had ocular demonstration of his facts, the physician now enjoys in regard to many internal organs. The surgeon also participates largely in this expansion of our field of view; while a collateral result is, that the physician in many instances finds himself under the dilemma, either of undertaking operations strictly surgical or of abandoning some departments of treatment and some important organs that custom has hitherto assigned to him. Many have had the good sense to consider simply their patients' advantage, and not the punctilios of a class; and thus there has been a considerable, and as I regard it, a very satisfactory demolition of old and artificial barriers between different grades of practitioners, which the future progress of physical diagnosis must still further tend to promote.

Take another example. By means of that modern optical triumph, the compound microscope, which takes us as it were, among the very elements of form and the rudiments of organic structure—a world we are apt to lightly regard, though it has infinite uses for us, as it has infinite beauties—by this an instructed practitioner, even one not highly gifted, but only conscientiously alert and observant can say with confidence of an organ deep in the wasting frame before him, beyond his touch, out of his sight, which emits no sound, and is the seat of no pain, "This gland has been certainly passing insidiously through this, or that, important destructive change; it is now so and so; I can accomplish this, or probably only this, for its relief; and this, or this, will be the end."

And not to weary you, gentlemen, with more examples from the field of diagnosis, the results of chemical examination, frequently seconded by the microscope, need only to be alluded to in order to take their eminently important place in this imperfect sketch, by the side of the other aids to physical investigation of the signs and footsteps of disease, conferred upon us by modern science.

As to the intimate nature of disease and of health, modern physiology is a platform on which all practitioners have an almost equal footing, where they meet and cross each other at every turn, and find everywhere the opportunity of a community of thought and action. All admit that disease is such a departure from a state of health as oversteps those undefinable limits which the organization will bear without strain or curtailment of its perfection. But these are not now such vague words as they might once have been; for vivid light has been thrown upon many of the abstruser problems that formerly perplexed us. The details of the interwoven structures and of the complex functions of our composite frame have been zealously and perseveringly traced by some of the acutest observers and of the keenest intellects that have ever lived; with a harvest of results so plentiful, so reliable, so mutually illustrative, and on the whole so marvellous, as

to make very much of the knowledge of even the last generation seem antiquated and obsolete. And we may accept it as a truth, that every step forwards in our knowledge of the healthy body, so it be real, must lead us right onwards, too, towards a better understanding of disease; and if of disease, then also of our power of counteracting it, whether in the way of prevention, alleviation, or cure.

As to modern treatment, I shall only remark, that the direct and obvious tendency of all modern progress has been to make it more rational and more simple—that is, more appropriate, first to the precise conditions more correctly recognized in each case; and next, to the degree in which interference on our part is found likely to be advantageous or otherwise to the sufferer.

No conceit of our great advances in the *medical sciences*, however, must beguile us into assuming that *medicine itself is a science*, or can ever become one, in the sense of our being ever likely to be able to practise it on principles unerring and exact. It is not in any true sense a science, but the *application of many sciences, and indeed of all appropriate and available knowledge, of whatever kind, to the relief of suffering*. It is really an *art*, as the father of medicine long since styled it; and woe be to those patients who fall into the hands of men aiming at treating all who come to them, and all diseases, on some single so-called simple principle, which can really be no other than the negation of all good sense and of all the well-understood conditions of our art. It is an art, however, which, while it must always be pursued with the very closest regard to the individual facts of the case, must in the interest of each patient be pursued in a *scientific spirit*, for thus only can the facts be duly interpreted and our treatment suitably applied.

And it seems the special glory of the advances in healing knowledge in our own day that they are of a kind to supersede those vague general observations by which a few rarely-gifted men could formerly, as now, make sagacious, pertinent, sometimes true guesses as to the nature and more latent relations of diseases (though these gifted men oftentimes fell into lamentable mistakes), while the generality steered without accurate chart or compass—or worse, under the deceptive guidance of some false, delusive, though vaunted, theory. Although still, in the uncertain and ever-varying phases of practice, we can none of us afford to disregard the aid of our own unwritten experience, or those general impressions left on our minds by a long series of empirical observations, in which as yet no clue to a satisfactory explanation has been described, these late advances are at the command of all who, being honest enough to desire to detect the nature of a disease committed to their care by a suffering fellow-creature, will, with ordinary intelligence, instruct themselves in the requisite and usually simple physical tests. So far as they extend, they are to be most highly prized. They bear the stamp of all true knowledge in being useful, available, and not apt to deceive; and, having been once acquired, they become henceforward the inalienable inheritance of all mankind, and doubtless the starting-point for future conquests.

The subject of anæsthetics is one which cannot be altogether passed over in this place, though it is hard to mention it and not to pursue it to the exclusion of all else.

Dim notices of the use of medicinal agents to prevent pain in surgical operations are not altogether wanting in very early times; and the desire and hope of finding some means for effecting this was certainly felt by more than one person during the last century. Even a method by compression of the nerves was actually tried in one of the London hospitals. But our present universal use of this eminent blessing to suffering human nature is the result, first, of the progress of pure science, not medical; then, of the applications of pure science by men devoted to particular specialties of practice; and both hemispheres share the glory of it.

Let us look at Cavendish, Priestley, and Lavoisier at work in their pneumatic laboratories, at Paddow, with

young Davy, in Bristol trying to make inhalation of gases useful in medicine, inhaling laughing-gas, and noting its effects; at a public lecturer at Boston, in America, nearly fifty years afterwards, exhibiting its well-known effects to an audience, among whom was a surgeon-dentist; at the sudden idea of this one to apply it as a remedy in his own case, for he was tormented with a toothache. It succeeded; but afterwards, when he had urged its adoption on a great operating surgeon, and it had been actually tried several times, the uncertainty of its effects caused it to be completely abandoned. But the idea had been too intensely impressed on some lookers-on to be ever again lost sight of. Faraday had already long since shown the great similarity of the effects of laughing-gas and of the vapour of ether, and this was familiarly taught to students in chemistry. But nearly two years still elapsed ere another surgeon-dentist, who had been present on the former occasion, tried the ether, and found it to succeed so perfectly, and to be so manageable, that he at once proclaimed it to the world; and it was soon adopted by the surgeons of all countries.

But now a pharmaceutical chemist of Liverpool, at the instance of a more gifted mind, suggested another substance, a product of modern chemistry, discovered simultaneously in Europe and America sixteen years before, which had been medicinally used, and even its name philosophically settled according to the analogy of its exact constitution by one of the first chemists of France. The gifted man was an obstetric practitioner of Edinburgh, whose fame already world-wide, will not rest hereafter solely even on so great a fact. After applying it in his own department of practice, the adoption of chloroform by surgeons, to the gradual exclusion of ether, rapidly followed; and all mankind will profit by it until, in the sure progress of the art, some other anæsthetic shall be found, without even the slight inconveniences of this one.

In reviewing the subject of anæsthetics, we cannot fail to be struck by two pregnant facts. The first is, that while surgery has chiefly felt their influence, and its practice has been modified by them in a remarkable degree, surgeons have been but passive recipients of the boon, which has been brought to them from other quarters, and even from a side branch of their own specialty, which some great ones among us have sometimes thought scorn of. The other is, that the noble sister art of physic (considered also as a specialty) has had no part or lot in this greatest of the applications of modern science to the alleviation of man's bodily pangs. I must, however, except Dr. Beddoes, and cannot omit to mention with grateful appreciation the important share borne by the late able and amiable Dr. Snow, both in the theoretical and practical parts of this great subject, as well as the recent labours of Dr. Richardson.

In this instance, as in almost, if not quite, all that most distinguish the modern art of healing, we see it fostered and advanced, not to say transformed, by the influences of general science in departments apart from and beyond ourselves, combined with those of the special sciences, which may with some propriety be called medical and practical, because they are prosecuted mainly by men engaged in practice, and with the object of applying them in the treatment of disease. Let not, however, individual promoters glory, or indeed a great number leagued as a profession, for that would be even less reasonable. It would almost seem that as "the earth bringeth forth fruit of herself, first the blade, then the ear, then the full corn in the ear," so the world in our time is reaping results all valuable for the good of mankind, which have been long, and in various modes and places, a preparing, and in contemplating which our feeling should be rather one of thankfulness than of exultation; and this feeling may induce us sometimes to ask ourselves, "Can we do anything now, and in the future, to help on, by united action, the harvests of a still brighter hereafter?"

This leads me to refer to the actual distribution, at the present day, in this and other civilized countries, of our professional power or force.

The immensity of the field of medical science and art is such, that no one mind has ever been able to embrace it all, and the daily enlargement of it in all directions must render it more and more difficult to do so. Hence the great specialties of medicine and surgery, however impossible it may be to draw a precise line between them, have long existed, and must continue to prevail. The grounds for them lie—1. In the necessity for a division of labour in large communities (large by concentration of numbers, or by ready means of intercourse). 2. In the somewhat equal proportions of grave and serious medical and surgical diseases, so called, under the circumstances of human life. 3. In the varying tastes of individuals, causing men to confine themselves, more or less, to one or other of these divisions of practice. But the great majority of medical men must be ready to undertake all treatment, since the exigencies of society require it of them.

Now the very same causes which have developed the healing art for ages under two principal divisions have, within a century, and especially of late, led to the multiplication of subordinate branches, often just as impossible to define by strict limits. On these a very few remarks are all that the time admits of.

Specialties, then, are natural products of a period of progress, and of certain favourable external conditions of society, and as such should be allowed free course to develop themselves according to their tendencies. The policy of the profession towards them should be always to retain them within its bosom, to hold them to their connexion with the whole, of which they form a part, and only to seek to restrain their growth and action, when it disposes them to an isolation, pernicious as regards their own usefulness, alien to the comprehensive spirit of our art, and a violation of our unity as one body.

Medical men, acting under some common impulse, are apt, like any others, to take a one-sided, or what is sometimes called a professional view of whatever new proposal seems to affect them as a class, or in a large number. Let us, however, consider that our ends coincide with the good of mankind, and that in estimating the good or the evil likely to be done by new specialties, we should appeal to no other standard than the public benefit. Is this or that suggestion for the advantage of the community in which we minister? Our own credit as a body, and generally our individual prosperity, will be found in the general good; and if otherwise, we should gladly yield it up to this.

Hence there are strong grounds for allowing specialties, whether promoted by smaller or larger numbers, to make progress according to their natural divergencies and powers of maintaining themselves. Some may originate on an insufficient and unreal basis, started, perhaps, by some supposed individual interest, and sustained by some strong personal bias, talent, or local circumstance: these will fail of themselves if they be left alone; and whatever harm they may do in diverting benevolence from more healthy channels, or wasting time and opportunities, these are probably smaller evils than the creation of a feeling in the public mind, with any degree of reason, that we are narrow, or opposed to the progress of our art.

What may be styled the natural specialties are those devoted to mental maladies, the obstetric, ophthalmic, and some others. These generally have reference to the natural distribution of organs in the frame, or are such as men readily accept, and see the propriety of, in their being manifestly for the convenience of patients as well as practitioners, and conducive to the advancement of knowledge. These are likely to increase in number, and to strengthen their footing. They should be held bound to the professional body by every available tie. Two things have given me pleasure in this point of view; the one that the College of Surgeons saw the wisdom some years ago of allying the surgeon-dentists of England to themselves by suitable links of connexion; the other that the great library of the College of Physicians was lately the scene under the auspices of its beloved and honoured President,

of one of the most astonishing historical displays of the mechanical appliances of the obstetrical branch of the art ever collected in one room. A happy augury, I thought it, of a larger and grander union, in time to come; of all branches and all departments, under some single spacious noble portico!

Were the whole profession thus at one with itself, there are many weighty objects which it might labour for with tenfold vigour and effect. I am content, for my part, to regard as of very secondary importance all attempts to obtain political influence or the recognition of merit by titles, whether personal or corporate. For I am well convinced that, whatever may be worthy of our ambition in this respect (and it does not seem much) will follow of itself, and without our efforts, if we are true to ourselves in a higher, and indeed our proper sphere; by striving to become more useful as practitioners, wherever we may be, either in our private rounds, where most must toil, or in some more public station.

With regard to our own better organization, it must of course be worked out by ourselves. We alone understand our needs; and the State cares little or nothing for what does not directly concern the public health, although we must acknowledge that it has shown itself, on many occasions, ready to forward our wishes, when these wishes have been suitably advanced. The institution of the Medical Council is a transitional step of immense import for our future unification, no less than the work performed by that body in the preparation of a common Register of all qualified practitioners, and in the publication of a Pharmacopœia for the whole kingdom. Its beneficial influence will likewise be gradually felt in better arrangements for admission into the profession on a uniform basis.

But there are many functions, in connexion with the Government, with so great a profession as ours might rightly ask to perform through its own well-appointed organs; in which, as a body, it now takes no share whatever; which are at present accomplished irregularly, almost as chance or caprice may determine, by a reference, either to one or other of the corporations, or to some individual selected by the minister, whose very name, perhaps, is not known, and who, therefore, practically, is not responsible to his own profession for the advice he may tender. By degrees, indeed, of late years, as the care of the public health has more and more engaged the attention of Parliament, this want has been in part supplied by the appointment of medical officers for special duties in governmental departments; and most ably have these performed their duties, as the documents from time to time issued by the Board of Health, under the Privy Council, among others, amply testify. And the labours of the Army Diseases Prevention and Cattle Plague Commissions illustrate in another way how the services of medical men may be most usefully elicited on special occasions or emergencies. More might be added to the same purport. A complete and recognized organization of the entire profession, however, would apparently be a measure of great importance in reference to our relations to the State.

But leaving these more public questions, and looking at the whole nature of our position, we may fairly ask ourselves whether in our corporate capacity, as a body of men concerned with such great human interests, we may not hope to do more than we have hitherto done to help forward those interests, for the advantage of our own day and of those who are to follow us. We have a grand inheritance from the past: we should hand it down much amplified to our successors.

Individuals have done, are doing, will continue to do, much. But I speak of the direction of a common endeavour, devised by forethought, tending to well-considered objects, and sustained by the united will of an enlightened, numerous, and, on the whole, powerful professional body, to promote and advance those branches of knowledge which lie at the foundation of a rational art of healing.

I am not here to flatter any man, least of all to commit

the little less than crime of the huge flattery of my own class, to the lowering of what should be our higher aims; and I say, with all love and respect for my fellows, and with a deep sense of my own shortcomings, that we are not doing, as a body, what we might do in Britain to extend and deepen the scientific foundation of our art.

In our corporate capacity, we ought to foster especially those departments of research which are least likely to be undertaken by individuals without such encouragement; which, indeed, can hardly be prosecuted at all without means and appliances beyond the ordinary reach of individuals. We need in England the public open establishment of means and apparatus for original research and observation, especially for our younger men, in the sciences ministerial to medicine, particularly physiological and pathological laboratories and for organic chemistry. These should be in part connected with museums, medical schools, and hospitals. The lay governors of great hospitals should be moved to consider it as one of their most urgent functions, to see that no unnecessary waste of the precious means of improving knowledge, placed under their keeping, occurs.

The progress which recent years have witnessed, points with sufficient clearness to the direction in which the next steps may be most profitably taken. It is in the field of exact scientific investigation into questions and problems which the latest advances have opened to view. Here each new fact and principle, patiently grounded on previous knowledge and established beyond dispute, though it may for a while appear an idle and unimportant addition to the common store, may fructify hereafter into some solid and useful generalization, applicable, in the most unexpected and startling manner, to human happiness and the success of our cure.

In any step taken by the whole professional body for the encouragement and promotion of the medical sciences, we should not, of course, look for immediate results of that kind termed, in common language, *useful*; that is, having an immediate and obvious application to some present use. We remember that great uses may long lie dormant, and at length overpower us by their splendour. *Witness chloroform.* Individuals are naturally prone to pursue studies which appear to them most likely to be crowned by an early result. Few have time or opportunity to labour for any result very far off, and for mere love of knowledge; but those who do should be most of all helped on and sustained. As a body, we might have a settled policy, and look further and deeper. Such is the nature of our studies, that at present real advances are to be sought in depth rather than in extent of work. It is only by going deep that we can hope to reach central relations, and such principles as may be at the same time simple and reliable; not simple by the fallacy of an incomplete view. We should encourage the less immediately useful matters of scientific research, such kinds as experience reasonably shows to give promise of great and wide though more remote benefits. The Royal Society was founded simply "for the promotion of natural knowledge," and what results for mankind has it not aided in achieving!

In a word, we have the certainty, from all history and from the nature of the thing, that out of knowledge will flow useful application; and well-instructed men now-a-days will not cavil or sneer at even the least advance, so it be real, into the realms of the unknown in natural phenomena, because it bears no immediate fruit or gives no present earnest of profit. The torch which illumines will ever be found also to warm and to cheer man's life upon the earth; and this is especially true in the medical sciences prosecuted as they are by men whose whole habit and tendency is to apply knowledge.

The time is too short for me to attempt even to enumerate the lines or provinces of research that might be thus encouraged; but there is one subject on which a few words may not be inopportune at the present time.

There is a sentimentalism, which I shall venture to

characterize as in some of its developments not robust or manly, and therefore not morally sound or grounded on right reason, which is inclined to bring popular indignation, excited by speeches at public meetings and by essays produced under an artificial stimulation, to bear on men of science desiring to investigate great principles in the doctrine of life by experiments on living animals. Having formerly, when circumstances led me into this region of inquiry, and in the performance of my duty as a professor of physiology, taken part in such experiments, and knowing well how vast an accession of knowledge useful to man has accrued, and will certainly hereafter accrue, from such experiments, I should be ashamed of myself, and deem myself to be neglecting a moral duty, if I omitted to take this opportunity of protesting with all my force against the imputation of "cruelty to animals" sometimes raised against medical men on this ground.

As inheritors of the labours, and let us hope of the scientific spirit, of Harvey, whose works abound with evidences that the discovery of the circulation itself was largely due to such experiments, we should be untrue to our ancestry and to our convictions if we hesitated to uphold, publicly if need be, the lawfulness, the expediency, nay the desirableness, of such experiments; and, as it seems also to me, if we failed in our corporate character to take more active steps than at present to promote these in their proper place and degree, among other kindred pursuits.

A society, respectable and praiseworthy when directing its shafts against the meaningless and selfish acts of vulgar and brutal natures, or when striving in various ways to diminish the pain inflicted on animals put to those human uses which general consent, no less than the widest view of all nature, sanctions, is no longer to be commended when it ventures to raise a prejudice against the refined and honourable inquiries of educated men, seeking to advance legitimately a branch of knowledge most nearly touching human interests of a lastingly high order. For every really forward step taken in the science of man's life, is a part of that progress which is indisputably adding to the sum of human happiness, not only in the present time, but in the future. It is only those well-meaning persons who are little acquainted with the necessary elements, and the excessive difficulty of such researches, and apparently still less with the motives of the higher class of scientific inquirers, who can presume to endeavour to thrust themselves into a province where no present abuse calls for interference. I think it would be wiser for the excellent persons in question to confine themselves to those spheres of exertion in which all good men and scientific men must heartily bid them God speed, rather than wear the appearance of attempting to add to their *éclat* as a popular society, by a foolish crusade against what can certainly be justified, and must even be applauded by all well-wishers of their own kind, if we admit, as society seems inclined to do at present, that to apply animals to purposes useful to man is one of the manifest ends of their mutual relationship on the earth.

In the country of Harvey, and in the bosom of the profession which derives so much glory from his name—in the country of John Hunter, of Astley Cooper, and of Brodie, there should be no doubt as to the free allowance of dissections of living creatures for the advancement of knowledge, whenever the course of investigation demands it, of which those only can properly judge whose minds are occupied with the pursuit. To the conscience and human feelings of these may safely be committed the discretion as to how far this exercise of man's prerogative over all the lower organizations may be carried, without the abuse of inflicting unnecessary pain.

Now that anaesthetics are in common use, physiologists, we may be sure, will be the first to employ them whenever the nature of their inquiry allows; and the public may be satisfied that—in Britain, at least—those who know most of the interior structure of the animal frame and of the movements, of whatever kind, that are the

manifestations of its wondrous life, would be the first to denounce the causeless infliction of one pang on the lowest of God's creatures. Let the indecorum not be committed of dragging such questions before public audiences, for which they are quite unsuitable. Let the opponents of legitimate experiments on the lower animals (and I believe they are few, even in the society to which I have alluded) desist from a course which, however well intended, cannot be required for their chief objects; and which may expose themselves to the charge once brought against persons of an altogether different stamp, of stopping the gates of knowledge, neither going in themselves, nor suffering those that are entering to go in.

I intended, gentlemen, had my limits permitted, to have adverted to several additional ways in which, as it appears to me, a united profession could find opportunities of promoting scientific culture; of which a principal one might be the employing more speedy and extensive means of making us acquainted with the productions of foreign medical literature than have hitherto being attempted. Men of science have a common field and common objects of pursuit, but not now, as once, a common language; for most of us, translations only can supply the defect; and translations, unless promptly brought to us and tolerably full, are of comparatively little value. Nor can our weekly and quarterly journals, conducted as they are with constantly increasing ability, and all of them, I think, comprising a foreign section, do much to satisfy this particular want.

Our New Sydenham Society is worthy of all praise, but its sphere is too limited, and its publications are restricted to its own subscribers, and these only 2500, too small a number out of so great a profession. The original memoirs and works in medicine and the allied sciences bear a considerable proportion to the whole of the scientific productions of the world; and some idea may be formed of the number of these from the fact that the separate scientific memoirs and works of all countries, of which the distinct titles could be ascertained as having appeared between the years 1800 and 1863 inclusive, brought together under the authority of the President and Council of the Royal Society, reach the astonishing total of 120,000, while every year's produce is becoming greater than the last.

The medical literature of Germany, France, Holland, and other continental countries, abounds in materials of great value to us, both as scientific men and as practitioners (as ours no doubt does to them). But unless we are kept fully aware, in each department, of the additions as they accrue, we are in danger of lagging in the race of improvement, and can hardly hope to do justice to our patients or to ourselves.

But, gentlemen, I must conclude. I would willingly have resigned into abler hands the task unexpectedly imposed upon me by your Council. Circumstances and my tastes have caused me for some time past to desire to play my humble part noiselessly in the world; and I have been less able than I could have sometimes wished to share even in the pleasure and the profit of professional gatherings. I have, therefore (more perhaps than some men), looked somewhat as a spectator, from the outside, on many of the more public doings of our profession, whose well-being, prosperity, and honour I yet esteem above all price, and am constrained by every motive to desire to promote. I must say that I have witnessed with delight every successive sign of a spirit of conciliation and approachment between the old, venerable, and most justly honoured, but still independent and detached, rather never yet-united, corporate institutions, to which so many of us owe an allegiance undertaken formally by a solemn act. It has seemed to me that we have been weaker for good than we might have been; and especially for the furtherance of those beneficent objects, which no class will pursue if not our own, and none so well as our own; which, therefore, it would seem to be incumbent on us to prosecute by all the means in our power; and which have apparently

been less thought of because of our divisions. Not real divisions of feeling, nor any wide or deep divergence of interests, but only a want of united action; through the continued existence, in too much of their traditional shape, of isolated institutions, which in their present form, we have somewhat outgrown, and which seem to need some considerable re-arrangement if not consolidation, if they are to represent the altered state of the whole profession, such as it has come to be in our own age of astonishing progress.

I have now endeavoured to convey to you, I fear at too great length, my general impressions on this head, I hope without offence to anyone and with sincerity, certainly very inadequately. I have long looked upon this Association as the element in our profession out of which stronger bonds of union between all ranks, classes, and degrees might be expected to grow, than out of any other—at least at present; for it is framed on the most comprehensive basis, and is organised so that all interests in all parts of our common country may find their place and voice in it.

May it be more and more every year an arena where the wisely expressed objects of its founders may be temperately, but steadily and earnestly pursued—above all, in a spirit of union! and may leading minds of our profession, whose co-operation we so much require and so highly appreciate, come more and more amongst us, to help forward that great and noble Art of Healing, to which, in one or other of its departments, the lives of all of us are devoted!

## Hospital Reports.

### LONDON SURGICAL HOME.

#### THREE CASES OF OVARIOTOMY.

(Under the care of Mr. BAKER BROWN.)

##### MULTILOCULAR OVARIAN TUMOUR—OVARIOTOMY—RECOVERY.

*Case 1.*—Mrs. M. K., æt. 35, has had two children and a miscarriage. For three years has been conscious of some enlargement of abdomen, which, however, was not marked until twelve months ago. During the last three months, she says, the increase has been rapid. Menstruation regular and normal till two years ago; since then occasionally very excessive in quantity; uterine cavity of normal length. For the last few months her health has been failing fast, notwithstanding the careful tonic treatment of her usual medical attendant, Dr. Evelyn Crook of Northfleet, Kent, by whom she was recommended.

Mr. Baker Brown diagnosed a multilocular ovarian tumour.

After the usual preparatory treatment, she was submitted to operation on the 19th of April, 1866. The incision was six inches long; ten pints of ascitic fluid were evacuated, and the tumour, which was very multilocular, extracted, bringing to view a thin and very vascular pedicle about six inches broad, springing from the right side. To this the clamp and cautery were applied with perfect success, notwithstanding its great vascularity, and the wound was finally closed by thirteen silver wire sutures.

On the second day she had fish for dinner; on the third, a chop. All the sutures were removed by the tenth day, and the patient made a very good recovery, leaving the "Home" on the 15th of May.

##### UNILOCULAR OVARIAN TUMOUR—TAPPING—REFILLING OPERATION—CURE.

*Case 2.*—Mrs. C., æt. 31, was admitted into the London Surgical Home, May 4th, 1866, and gave the following history:—

Married, and the mother of three children, the last five years old; had a miscarriage a year later. At the age of

17, thought there was an unnatural enlargement of the abdomen, but did not communicate her fears to any one. She married at the age of 21, and from that time noticed a progressive increase of abdomen, apart from and after each confinement. About the period of the miscarriage, four years ago, she drew the attention of her usual attendant to her condition, and the result was that he tapped her, removing fifty-six pints of clear limp fluid. There was no return until nearly two years after this, when it began again to enlarge very gradually. During the last nine months the increase has been rapid, and there is now a moderately-sized fluctuating tumour.

On examination Mr. Baker Brown came to the conclusion, that the tumour was not true ovarian, but rather a dropsy of the Fallopian tube. Uterus measured two and a half inches; menses regular and normal, and general health good.

On the 10th of May Mr. Baker Brown operated in the presence of a large number of gentlemen.

The incision through the abdominal walls, about four inches long, exposed a thin walled cyst, which he emptied of about ten pints of clear limp fluid. He then withdrew the cyst, which had no adhesions, bringing into view the pedicle springing from the left side of the uterus and having the ovary attached. The clamp was applied behind the ovary, and the pedicle divided by the actual cautery in the way which he now advocates, and with perfect success. The wound was then closed by silver sutures over the pedicle, which was allowed to drop from the clamp by its own weight. The operation occupied nine minutes.

Careful examination of the tumour by Dr. Barratt confirmed the diagnosis. The ovary removed was the seat of cystic degeneration in an early form.

It is unnecessary to enter into the details of the progress of the case. Suffice it to say, that she made an excellent recovery, had not a single dose of medicine, and left the Home on the 16th day.

##### MULTIPLE OVARIAN TUMOUR—OPERATION—RECOVERY.

*Case 3.*—Mrs. C., æt. 29, has had two children; the second still-born seven months ago. She then for the first time noticed unnatural enlargement of abdomen, though she had felt unusually heavy during her second pregnancy. Menses regular and general health good.

Diagnosis, multilocular ovarian tumour.

Eight days after admission—viz., on the 29th of May—Mr. Baker Brown performed ovariectomy. The case was most simple, without complications, occupying scarcely more than ten minutes. The pedicle was successfully treated by actual cautery. The tumour presented an example of the multiple form, consisting of a large cyst containing an immense number of small cysts. Twelve pints of dark fluid were removed in the course of the operation.

In a fortnight she was allowed to be outside the bed, and she made a good recovery, notwithstanding the formation of a troublesome abscess in the abdominal parietes; and she left the Home in about five weeks.

## THE CHOLERA WARDS OF THE LONDON HOSPITALS.

In resuming our account of the treatment pursued in the several hospitals of the metropolis, we necessarily refer chiefly to the London Hospital, which still continues to admit so many cases. There are in the London Hospital 139 beds allotted to cholera cases, and, if necessary, the wards could in a short time be prepared to receive 160 cases. The largest number at any time under treatment has been 116. The staff on which this work devolves consists of four physicians and five medical residents. These are aided by three head nurses, nearly seventy nurses, and five lady volunteer nurses. At one time the disposal of the dead was a great difficulty; but this seems to have

been readily overcome. The following is a summary of the patients admitted into the cholera wards of the London Hospital from the 10th July to 16th August:—

## CHOLERA.

|                | Admissions. | Recoveries. | Deaths. |
|----------------|-------------|-------------|---------|
| July 10 to 19  | 17          | —           | 5       |
| Week ending 26 | 100         | 4           | 58      |
| August 2       | 158         | 31          | 73      |
| “ 9            | 89          | 37          | 66      |
| “ 16           | 67          | 36          | 40      |

Totals . . . . . 431 . . . . . 108 . . . . . 242

## CHOLERATIC DIARRHŒA.

|                |    |    |   |
|----------------|----|----|---|
| July 10 to 19  | 7  | —  | — |
| Week ending 26 | 26 | 9  | — |
| August 2       | 28 | 38 | 8 |
| “ 9            | 35 | 15 | 3 |
| “ 16           | 27 | 22 | 1 |

Totals . . . . . 123 . . . . . 84 . . . . . 12

On the last date, August 16th, there remained in the hospital 108 cases, of which 81 were cholera, and 27 choleraic diarrhœa.

As to treatment, similar measures to those already described by us have been continued. Some other remedies have also been tried, among which we may name the camphor solution of Rubini. This has only been a failure. It is intensely disagreeable to the patient, and utterly impossible to be taken in the stage of collapse, as the solid particles of camphor only deposit on the mouth. We may here correct the dose of calomel which we named last week as prescribed by Dr. H. Davies. He gives a scruple for the first dose, and after abandoning Stevens's saline, the sulphuric acid with prussic acid, and podophyllin with camphor, seems to place most reliance on the calomel treatment.

We mentioned last week that some thermometrical observations are being made at this hospital. It is not improbable that statistics of this kind may hereafter prove of considerable value. The details at present can be of little value. We may mention, however, that comparative observations of the internal and external temperatures have in some instances been made, and seem to imply an increase of internal temperature as noted *per vaginam et per anum*, in proportion to the decrease externally indicated by the thermometer in the axilla. It would also appear that during the feverishness of reaction the internal temperature seldom rises above the normal heat. Other observers will probably collect statistics of this nature, and when the epidemic shall have passed away we may look for details which cannot yet appear for want of time to arrange them. It is not improbable that much interesting matter relating to the outbreak will appear in a future volume of the “London Hospital Reports.”

## GUY'S HOSPITAL.

THERE have been some other admissions during the week. Nothing fresh in the way of treatment, except that the permanganate of potash has been prescribed in a couple of cases by Dr. Moxon.

## ST. GEORGE'S HOSPITAL.

Two cases were admitted on the 14th. One was that of a cattle driver found by the police in a state of insensibility in Hyde Park. He died in about twenty-four hours afterwards, and a post-mortem examination was made. It is probable that at all the hospitals where a few cases occur a more detailed record of the cases will be kept and more autopsies made than where the number of the cases is so great as to over-work the staff. A considerable number of cases have been divided amongst the other hospitals.

## BELLISLE HOSPITAL SHIP.

As we named last week, several sets of cases are here being treated by different methods, and will be very valuable when sufficient numbers are collected to contrast the mortality under various modes of treatment. A most important experiment has been tried on eight cases—viz., abstaining from administering any drug whatever. It is undeniable that our facts as to the progress of the disease *unaided* by any treatment are but few. We are aware of several instances in which an attempt has been made to leave the disease to Nature, and that the results have been far from discouraging. The expectant method is not likely to find favour in so urgent a disease. Nevertheless, it has been tried, and some physicians have prescribed a mere *placebo* with a success equal to that obtained by others from very heroic doses of potent drugs.

## RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

## DR. LYONS'S CLINIQUE.

## DIARRHŒA: ENGLISH CHOLERA: TRUE CHOLERA.

SEVERAL cases of “Diarrhœa,” with more or less of abdominal pains, have been admitted in Dr. Lyons's Clinique since our last notice—in two instances with the alarm on the patient's mind that it was a cholera seizure. Hot fomentations, with the mild castor-oil carminative draught, masked by a small quantity of tincture of opium, gave speedy and permanent relief, and the patients were discharged convalescent.

In drawing attention to the diagnosis of “Diarrhœa” and “Cholera,” Dr. Lyons observes on the necessity for definite pathological knowledge as a basis for the enumeration and classification of the various forms of disease confounded under the head of “Diarrhœa.” The term, as ordinarily understood and employed, describes a symptom, but fails to define a recognizable diseased state, and as well might a patient, in many instances, be said to have died of “Cough” as of “Diarrhœa.” In another place he has forcibly remarked:—“In the medical history of former years such terms as ‘diarrhœa’ or the ‘fluxes’ were perhaps sufficiently admissible, but neither of these words, unless within very definite and precise limits, can be now accepted in the language of Clinical Medicine or Pathology. So far as they are taken to express a phenomenon of disease—not a disease itself—their use is proper; but it will be hardly necessary to say that, like the terms “Emesis,” “Hydrosis,” “Diuresis,” &c., Diarrhœa constitutes a symptom or phenomenon of disease, not any constant or established form of diseased action recognized as such in the pathological scale.” So much, it is not improper to urge at the present moment when in connexion with “Diarrhœa” so many vague ideas fill the popular and even the professional mind. That cases recorded as deaths from “Diarrhœa” are frequently due to such varied and opposite causes, as “Typhoid Fever,” “Tuberculosis of the Lung,” “Dysentery,” “Pneumonia,” Dr. Lyons has already elsewhere fully shown, while diarrhœa *per se* has rarely been a fatal disease within his experience at home or abroad.

## FORMS OF DIARRHŒA.

Under the head of “Diarrhœa,” considered as a morbid state, attended with more or less flux from the bowels, may be recognized the following forms:—

1. Atonic Diarrhœa } A form of disease corresponding  
or } in all essential particulars to the  
Diarrhœa Lienterica } of the older authors.
2. Biliary Diarrhœa: Due to deranged or increased biliary secretions poured out into the intestinal canal.
3. Crapulous Diarrhœa: Due to the ingestion or accumulation of food of indigestible quality or in excessive quantity.
4. Congestive Diarrhœa: (a) Acute; (b) Chronic.

(1.) *The Atonic Diarrhœa or Lientery* constitutes a form of affection not uncommon in children, but occasionally seen in the adult, and then of much more obscure character and often overlooked, and when treated by astringents proving remarkably intractable. Such remedies, in fact, but aggravate the malady, under which the patient labours. When it continues for any lengthened period, as it often does, if misunderstood and improperly treated, it leads to great prostration of the system. Feverish symptoms seldom attend this condition to any marked degree; thirst is usually complained of; the appetite fails; and a sense of nausea is often felt, especially during the heat of the forenoon in the summer months. A relaxed state of the bowels gradually comes on, and though disregarded at first, it becomes troublesome, chiefly from the frequency of its occurrence and its continuance. Pain is seldom felt to any great degree, and, if present, it is of but a passing character. But perhaps the most remarkable phenomenon of the disease is the almost total suspension of the digestive, assimilative, and absorbent functions, the *egesta per anum* often differing but little in appearance from what is ingested as food by the mouth; thus solid fragmentary particles of various kinds of food, animal as well as vegetable, can be readily detected in the *fœces*, such articles as bread, potato, carrot, meat-fibre, &c., retaining their natural colour, consistence, and general physical characters. In the Crimea, where this affection prevailed on a large scale amongst both officers and men, it was a subject of remark amongst the men, that "it was no use eating their victuals, as they passed through them undigested and exactly as they were taken in."

In private practice, Dr. Lyons has seen well-marked examples of the disease which yielded to judicious medication, non-astringent, and the use of a carefully-managed regimen continued over a protracted period.

(2.) *The Bilious Diarrhœa* demands especial attention at hands of the practitioner. It is essentially dependent on an irritated state of the intestinal mucous membrane, due to the secretion of bile in excessive quantity or morbidly stimulating in quality. In the severe forms, nausea, greenish or yellowish bilious vomiting, frequent copious and fluid yellow stools, with occasionally much flatus and a burning sensation about the anus, are complained of. A slight icteroid tint is at times observable in the conjunctiva. Derangement of the liver being obviously the cause of the malady in this form of disease, all rational therapeutic measures must be directed to this organ.

(3.) *Crapulous Diarrhœa* has been already sufficiently considered in the notice previously given. When attended with cramps, vomiting, and purging, the liability to mistake it for cholera is greatly increased. The danger of such mistake and of the treatment of the case by astringents has been already pointed out.

(4.) *Congestive Diarrhœa*.—This form of the malady may be considered in a future communication.

## Reviews.

**CHOLERA IN ITS HOME**; with a Sketch of the Pathology and Treatment of the Disease. By JOHN MACPHERSON, M.D., late Deputy-Inspector of Hospitals, H.M. Bengal Army. Pp. 155. London: Churchill and Sons. 1866.

**THE ANTIDOTAL TREATMENT OF THE EPIDEMIC CHOLERA**; with Directions, General and Individual, for the Prevention of the Disease. By JOHN PARKIN, M.D., F.R.C.S., late Medical Inspector for Cholera in the West Indies. Third Edition. Pp. 321. London: Churchill and Sons. 1866.

The first of these books is written by a gentleman who has had very ample opportunities of witnessing the progress of cholera in the East Indies, and he not only supplies a great amount of practical information as to the nature, cause, and treatment of the disease, but he has evidently made

himself well acquainted with the literature of the subject from the earliest to the most recent times. If the perusal of Dr. Macpherson's paper does not leave any very definite impression upon the mind as to the pathology or the causes of cholera, the result must be attributed to the intrinsic difficulty of the task undertaken by the author, and not to any deficiency of knowledge or zeal in investigation, or of facility of description. The very fact that he offers no dogmatic opinions is, in our estimation, perfectly consistent with his thorough acquaintance with the disease.

With regard to the question of contagion, Dr. Macpherson, while admitting that human intercourse has a share in the propagation of the disease, contends that it is contagious in a very slight degree in Lower Bengal. He states, as the result of his experience, that the attendants who are employed to rub the extremities of the cholera patients very rarely fall sick; that the native servants have no fear of attending their masters and mistresses when ill; that the sweepers who remove the excreta and the washermen who wash the clothes never suffered; and that he has never seen a medical officer or subordinate on duty in hospital attacked. He adds that for a series of twenty-five years at least only one resident medical practitioner has died of the disease in Calcutta, that he has never had reason to imagine that the performance of post-mortem examinations was dangerous to himself or his assistants, and that although he has spent hours and days in a cholera atmosphere without taking any precautions he never had the disease.

On the all-important but very unsatisfactory subject of treatment, Dr. Macpherson has not much novel information to afford. He distinctly repudiates what is called the eliminative plan, and when there is the faintest suspicion of cholera he cannot recommend the employment even of mild emetics or aperients, and he especially objects to castor-oil. He urges the necessity of checking the preliminary diarrhœa by means of astringents and opium, and the latter medicine he thinks useful when the disease is fully developed. Alcohol and diffusible stimulants may be employed in moderation, ice may be put into the mouth, and warmth may be applied to the surface of the body.

Dr. Parkin's book, which has reached a third edition, possesses very considerable merit, and is founded, like Dr. Macpherson's, on great practical experience, but it is essentially dogmatic on the subject of treatment. He conceives that an antidote and a specific exist for cholera, and that the agent possessing these properties is carbon, employed either in powder or in the form of carbonic acid. It is not very clear on what theoretical grounds Dr. Parkin advocates the employment of this substance in cholera, but he declares that its use has been most successful in his hands. Carbonic acid is to be given by means of effervescing draughts, or if the patient objects to take it in this form, the carbonated alkali and the acid are to be administered one after the other.

**NINETEENTH REPORT OF ST. MARK'S OPHTHALMIC HOSPITAL AND DISPENSARY FOR DISEASES OF THE EYE AND EAR.** Dublin. 1864-66.

This report embraces a period of eighteen months, from the 1st October, 1864, to the 31st March, 1866; the hospital year will in future begin on the 1st of April, instead of on the 1st of October, as heretofore; and the change has been considered desirable in order to facilitate the making of special returns to the Dublin Board of Superintendence, and to the Treasury. In other words—the Treasury year, the year of the Dublin Hospitals' Board, and the year of St. Mark's Hospital, will in future be identical. It is scarcely necessary to say that this report keeps up its old repute. One fact may be noted—that whereas ninepence per day had been previously charged for maintaining

patients sent in by the Boards of Guardians, "owing to the great rise in the price of provisions, &c., that sum has been found insufficient, and it has been considered necessary to increase it to *one shilling per day*." The whole financial scheme of hospital maintenance of patients must be largely affected by the late and present famine prices.

## London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 22, 1866.

### THE HOSPITALS OF PARIS AND LONDON.

CONSIDERING the contiguity of England and France, and the community of scientific interests between the two countries, the difference existing between the Hospital system in each is exceedingly remarkable, but still it may be readily explained by reference to their respective political constitutions. In our own country, as we well know, the plan of local self-government is, or rather has been, carried to its utmost limits, till at last common sense and common humanity have revolted against the abuses which the excess of individual liberty has created; while in France, the very opposite principle of centralization, however abhorrent to the British mind, appears to have produced some very happy effects, and what is more, it seems to be in perfect harmony with the sentiments of our Gallic neighbours.

Our own Hospital system, being founded exclusively upon the principle of self-government, presents the most striking anomalies, and is prevented only by the general good sense of the community from leading to the greatest abuses. On the one hand we find palatial institutions, endowed with enormous funds, falling far short of the beneficent objects no doubt contemplated by their founders, and on the other we see inferior, though not less reputable establishments, merely struggling to keep their heads above water by continual appeals to the charity of the benevolent; while a great mass of the sick poor, who have neither the interest nor the good fortune to obtain admittance to the Hospitals, are relegated to the tender mercies of the administrators of the Poor-laws.

As a necessary consequence of this state of affairs it happens that many of the sick poor are lodged and cared for in our metropolis and our large cities in a style which might be envied by their richer neighbours, while numberless others of the same class are consigned to the miserable accommodations afforded in the wards of the workhouses, where the principle of self-government has produced the disastrous effects so often recorded. It also follows from our English system that the classification of diseases and their treatment in special hospitals is almost unknown, except in some few cases; and hence also arise the inequalities observable in our mode of appointing and remunerating the Medical Officers, some of these gentlemen occupying positions of considerable independence and enjoying adequate salaries, while

others, no less deserving, are allowed to languish in the cold shade of neglect, and to struggle for a bare subsistence at the hands of unfeeling taskmasters.

The system in Paris (and what is true of Paris is equally true of all parts of France) is entirely different, and the hospitals and infirmaries for the sick, instead of being dependent upon private charity, are institutions which are provided for and governed by the State. They all form portions of the Department of Public Assistance, which takes under its charge all kinds of poverty and suffering, and sends the sick poor to the hospitals, and the aged and infirm to the various *hospices*, for which word we have no equivalent English term, as it represents the favourable aspect of our workhouses without their attendant mismanagement.

It is true that the public in general subscribe nothing in France to the support of the hospitals, if by the term subscription is meant the appearance in print of a number of names followed by the amount of donation which each one may, if he pleases, present to the respective charities, and in return for which each one generally expects some corresponding privilege. But then by the centralizing system, to which we have referred, every one in Paris is compelled, although indirectly, to contribute, whether he pleases or not, to the maintenance of the hospitals for the sick and infirm, and as the tax is universal, it is very light, is very little felt, and has never been made the subject of complaint.

From a little work lately published, entitled a "Winter in Paris," by Mr. FREDERICK SIMMS, M.B., containing some very useful information on the medical institutions and the sanitary condition of the French capital, we learn that the sources from which the Parisian hospitals derive their income are from real property, rents of houses, rents payable by the city of Paris, money derived from the cutting of wood in different forests, from the theatres and other public exhibitions, and from other miscellaneous quarters, so that while there is an ample revenue for the care of the sick and infirm, no individual feels the burden of the impost. Then the administration of the revenues thus received is vested in a Director-General and a Council of twenty members, of which the Prefect of the Seine is *ex-officio* the President, and the admission to the hospitals is regulated by this Council, or by persons acting under its direction. Thus it happens that all the sick and infirm have an equal chance, and are not made to be dependent upon a governor of an hospital for their admission to its benefits; and again, some cases which are unsuitable for an hospital, but which are necessarily admitted into our own hospitals because recommended by a governor's letter, would be sent in Paris to the *hospices*. In accordance with the same spirit and practice of centralization, the Medical Officers of the Hospitals receive their appointments after competitive examinations, and not as matters of private favour and solicitation.

While thus drawing a comparison, however, between our own hospital system and that of France, and point-

ing out some of the advantages of the latter, we are by no means insensible of the evils attendant on the French system, and probably a combination or modification of the two systems might be profitably introduced; but it must be admitted that, looking to the present comparative treatment of the sick poor in Paris and London, it would certainly appear that the French sick poor are in the better condition.

THE *Lancet* of August 11th has not favoured us with any information from "Our Own Correspondent, Southampton," but with some remarks from Dr. MACLEAN. A few months ago, if I remember correctly, the Doctor had lost all confidence in most of the vaunted remedial agents for cholera. JOHNSON'S castor-oil treatment met with no favour at his hands, whilst he considered the novel and funny mode of procedure (if the seriousness of the question admitted of such phraseology), that of applying ice-bags along the course of the nervous centres worthy of consideration and trial. It would appear that after lengthened experiments this suggestion has been discarded as worse than useless. Dr. MACLEAN spoke approvingly of opiates and astringents in the premonitory stage, in which he may rest well assured that his view will be endorsed by a large proportion of practical men.

Elimination by the skin and opiate astringents will cure 99 per cent. of those who have tolerable constitutions in the premonitory stage. In his letter, dated July 30th, 1866, the Doctor again becomes visionary, and tells us that the method of disinfecting the stools and sewers by means of this powerful agent (carbolic acid) is being actively followed at Southampton, and, to this, in great measure, he attributed the comparatively limited area within which the disease up to this time had been confined. He commenced with the assumption that the stools and the sewers are infectious, and then boldly asserted that they had been disinfected!

What can Dr. PARKES, whose name has been introduced, have to do with disinfection? He has written a book on cholera, and contributed a number of facts, with the view of demonstrating the non-contagious character of the disease. It is impossible that his association with the Privy Council, in the capacity of Medical Adviser, should have made him a convert to doctrines he had previously opposed.

That carbolic acid and the hogsheads of stinking stuff which have been thrown about the streets of Southampton could have done more than frighten people of the place remains to be proved.

Choleraic disease has shown itself indiscriminately, as in 1849, in all the dirty localities of Southampton. Connected with extensive practices in the town, I may certainly write with as much authority as a gentleman whose official duties necessitate his spending most of his time at Netley, several miles from the scene of action.

There have been but three deaths from cholera since the 9th; fifteen during the present month, and last week the aggregate deaths were only two above the average.

## Notes on Current Topics.

LONDON WATER.---From the report of Dr. Letheby it would appear that during the month of July a reduction in the quantity of organic matter was found in the waters of all the companies. This reduction is attributed to the increased care with which the processes of filtration were conducted, and it is naturally enough suggested that, "all discoverable traces of organic matter may be removed from water, and yet it may still contain enough of the minute germs of disease to manifest its morbid action whenever it is used." Thus, while filtration through proper substances will remove decaying organic matter, and therefore ought not to be neglected, we should, at the same time, take steps to destroy any living germs capable of producing disease. These germs may be destroyed by certain agents, such as chlorides of zinc and iron, carbolic acid, &c. But the agent on which most reliance can be placed is heat. While, therefore, we filter through charcoal to remove decaying matter, we should boil all our water to destroy the vitality of those living germs by which cholera and other diseases are supposed to be propagated.

Let every family put aside sufficient boiling water from breakfast to serve for drinking purposes during the day, and a great danger would be removed. Filtration is good, boiling perhaps better; but both would certainly be best of all.

DEATHS OF PARISIAN PHYSICIANS FROM CHOLERA.---Among the victims of the epidemic in Paris three physicians, MM. Berard, Gibert, and Chaussier, may fitly be mentioned in a medical journal. M. Berard was a proprietor of the *Gazette de France*, and having gone to Paris from his country home at Blois, was seized during the night after his return, and died in the afternoon of the next day. Perhaps the case may illustrate the comments in Dr. Lyons' clinique reported in our last number, as to the greater effect of terrene and atmospheric conditions in a new locality. M. Chaussier was son of the surgeon who rendered the name so celebrated. M. Gibert has been one of the physicians to St. Louis for some twenty years, and his works on the skin and syphilis are well known. He was strongly opposed to the general opinion, that cholera is preceded by premonitory diarrhoea, and may be almost said to have fallen a victim to his persuasion; for we hear that he suffered several days from relaxed bowels, which he refused to treat medicinally.

A grant of money has been made by the Treasury to the Department of Health, for the purpose of conducting a special series of experiments and researches in connexion with the present outbreak of cholera. Mr. Simon will conduct the inquiry.

WESTMORELAND LOCK HOSPITAL, DUBLIN.---At a special meeting of the governors of this hospital, held on Saturday last, the 18th inst., Benjamin F. McDowell, Esq., M.B., T.C.D., was elected unanimously a visiting surgeon to the hospital.

DR. O'BRIEN, Medical Officer of Galbally Dispensary, county Limerick, was on Monday, the 20th inst., admitted a Fellow of the Royal College of Surgeons in Ireland.

BELFAST BRANCH OF THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—Dr. Browne, R.N., the treasurer of this local branch of the above society, begs to acknowledge the receipt, through Dr. Stewart, of £1 ls. as a subscription from Staff Assistant-Surgeon Mosse, Gambia.

## MORTALITY OF THE TROOPS IN CHINA.

THE Select Committee appointed to inquire into the Mortality of the Troops in China, have just issued their report, which we now proceed to analyse.

From the 1st of March, 1865, to the 1st of March, 1866, the 2nd Battalion of the 9th Regiment lost 200 men by death and invaliding home, out of a total strength of 838 men. The total deaths were 85—more than one-tenth of the strength for one year's mortality!

The 2nd Battalion, 11th Regiment, between June 1, 1865, and March 1, 1866, lost 258 out of 716, or more than one-third of the strength, by death and invaliding. The total deaths were 94, or more than one-eighth for nine months' mortality!

Besides these, the case of the 99th Regiment has particularly attracted the attention of the Committee. It appears that on the 15th of September, 1864, the 99th, then at Hong Kong, and in excellent health—there being only 31 cases in hospital out of a total strength of 684 men—was ordered to proceed to Kowloon, to occupy huts there. This order produced remonstrances from the principal medical officer and the regimental surgeon, who reported that "greatly increased sickness and mortality will follow the change, and the health of all will be deteriorated." In spite of these representations, the move was carried into effect, whereupon the following sanitary state ensued:—

| DATE, 1864.        | STRENGTH. | IN HOSPITAL. | FEVER CASES. |
|--------------------|-----------|--------------|--------------|
| September 14 . . . | 683       | 31           | 3            |
| October 14 . . .   | 623       | 123          | 81           |
| November 14 . . .  | 619       | 161          | 11           |
| December 14 . . .  | 612       | 97           | 26           |

The Committee express distinctly their opinion that the sanitary state described was entirely due to the unhealthy condition of Kowloon as a station, of which the military authorities had been forewarned by the medical staff.

We now follow the Committee to the case of the 2nd Battalion, 9th Regiment, which arrived at Hong Kong in February, 1865. On the 1st of March it was 838 strong. By the 1st of March, 1866, there were

|                              |     |
|------------------------------|-----|
| Invalided home . . .         | 145 |
| Deaths in China . . .        | 55  |
| Diminution of strength . . . | 200 |

Further, of those invalided, 30 died on the passage home, raising the total deaths to 85—more than one-tenth mortality for one year! To this should be added the deaths of 6 women and 24 children belonging to the regiment, besides 27 women and 40 children invalided between February and October, 1865.

The next case considered is that of the 2nd Battalion, 11th Regiment, which on the 1st June, 1865, numbered 716 men. Between that date and 1st March, 1866, there were

|                              |     |
|------------------------------|-----|
| Invalided home . . .         | 193 |
| Deaths in China . . .        | 65  |
| Diminution of strength . . . | 258 |

Of the invalids, 29 died on the passage home, making a total of 94 deaths, or more than one-eighth of the total strength in nine months.

In addition to these losses, there died of this battalion, between June and October, 3 women and 28 children; and 21 women and 28 children were invalided home.

The causes of this frightful mortality are ascribed by the Committee to the following causes:—

"1. The unhealthiness of the season 1865.

"2. Exposure to heat and malaria on duty.

"3. Want of barrack accommodation for the number of troops stationed at Hong Kong and Kowloon; the inadequacy of the huts and hired buildings to the sanitary requirements of Europeans, and the occupation of huts at Kowloon during the progress of excavations."

As to the first reason, the Committee have only some

contradictory evidence to offer, so that it may be passed over as of slight consequence. As to the others, it is established that the general in command had full authority, if not positive instructions, to transfer part of the troops to Japan; but, although warned of the consequences of a residence at Kowloon and Hong Kong, he retained the men in those stations, where they could not be properly provided for, to weary them by guard and other routine work, and this when it is clearly shown that hired watchmen could have discharged these duties—indeed had been previously employed for this very purpose.

Dr. Logan, Dr. Saunders, and Dr. Rutherford had all previously drawn attention to the "necessity of European troops having many nights in bed between the intervals of duty." Six or seven nights in bed was considered the minimum, but we find from the report that this was on one occasion reduced to two, and on another to one.

In respect to the overcrowding, it appears that in 1863 the War Department recognized 1000 to 1500 cubic feet per man as necessary for Europeans in tropical climates. Yet what are the facts proved before the Committee? Barracks abandoned for their insalubrity, were again occupied by small detachments and by families of married soldiers. Further on we read:—

"The general hospital is stated to be capable of holding 120 patients, at 1063 cubic feet. This hospital, at 1500 cubic feet, would only hold 84 patients; but, from want of hospital accommodation, it is stated that no less than 195 men were placed in it for treatment."

On the 1st April, 1865, the following was the state of the garrison at Hong Kong:—

|                                         |     |
|-----------------------------------------|-----|
| Troops to be provided for . . .         | 889 |
| Actual accommodation on old scale . . . | 849 |
| On new scale of 1000 cubic feet . . .   | 592 |

To which are to be added 38 married soldiers and their families, for whom there was no permanent accommodation.

"There existed, therefore," says the report, "a normal deficiency of barrack room at Hong Kong. This deficiency was increased by the arrival of the 2nd Battalion, 11th Regiment, and was met by over-occupying the barracks, by hiring buildings, and by quartering 250 men, married and single, in the huts at Kowloon, and by occupying the condemned ship *Hercules*."

As to the fitness of the hired buildings for the purpose to which they were put, we find in July, 1865, the following:—

|                                              |      |
|----------------------------------------------|------|
| Troops to be provided for . . .              | 1598 |
| Actual Accommodation, <i>old scale</i> . . . | 1377 |
| Deficiency . . .                             | 216  |

Colonel Jenner thus describes these hired buildings:—

"The ventilation was bad; they had to make ventilation after it was occupied; there were no latrines; the men had to go down in the hot sun upwards of a quarter of a mile, into the bush at the back, to answer the calls of nature. There were no places for cooking; they had to cook in the open sun in rear of the barracks, where there was a spring of brackish water, which they had to drink. In fact it was misery itself. The only means of getting into the upper story was by bamboo ladders."

Some unsuccessful attempts were made to provide for some of the troops in ships—but for want of proper instructions from home, the admiral in China afforded no assistance:—"150 men went on board the *Princess Charlotte*, by the kindness of Captain Nolloth."

So testifies the Committee. How is it that our troops should at any time depend on the kindness of a single captain for the accommodation that the government ought to provide. We have touched on the facts in the report which have a medical aspect. It is scarcely the province of a medical journal to attempt to weigh the feeble con-

demnation of the committee, or to apportion the blame due to the several parties inculpated. Our own profession has again only shone the brighter from the light shed on the subject by the enquiry, and once more we have a right to ask why the recommendations of the medical staff should be set at nought by incompetent commanders?

## Correspondence.

### POOR-LAW MEDICAL REFORM ASSOCIATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your giving insertion to the annexed correspondence. I rejoice to see that another Medical Inspector, Dr. Markham, has been appointed by the Poor-law Board—a sign that the medical element is in the ascendant, and I trust the time is not far distant when the sick poor of England and Wales and their medical officers will be treated with due consideration.—I am, &c.

RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, 11th August, 1886.

Subscriptions forwarded to the Association:—

Elkington, George, Southam, 5s.; Grimbley and Francey, Banbury, 10s. From the Bethnal-green Union the following: Welsh, C, 10s.; Haycock, G., 10s.; Brotherton, W. R., 10s.; Lyel, B., 10s.; Burgess, F. J., 10s.; Massingham, J. E., 10s.; Defriez, J. E., 10s.

12, Royal Terrace, Weymouth, July 24, 1886.

SIR,—I perceive a Bill is now before the House, brought in by yourself and Mr. Earle, entitled a Bill to amend the Act providing Superannuation Allowances to Officers of Unions and Parishes, &c.

In the first Clause of that Bill, it is stated "The Superintendent Registrar and the Registrar of Births and Deaths appointed to any union or parish shall be deemed an officer within the operation of the statute," &c. I respectfully beg of you to add the words *medical officer*, and my reasons for asking this boon is that for the sake of the poor, you should be able to superannuate your medical officers when unfit for the service, which a retiring pension will enable you to do, otherwise they must continue in the service if poor, for the sake of a mere living. In addition to this, it is but just to the medical man himself that after passing not less than twenty years in the service of the poor-law—a service which at all times is most fatiguing and most assuredly tends to shorten life—that he should have a retiring pension. I respectfully beg to call your attention to my letter of the 9th inst.—I have the honour to be, yours most obediently,

RICHARD GRIFFIN.

Right Hon. Gathorne Hardy, M.P.

Poor-law Board, July 25, 1886.

SIR,—I am directed by Mr. Gathorne Hardy to acknowledge the receipt of your letter of the 24th inst., and to say that no alteration of the kind can be made during the present year.—Your obedient servant, J. STEWART HARDY.

### STATE OF THE DRUG TRADE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reply to the gentleman who addresses you under the head "State of the Drug Trade," I beg to say that I would be the last to profess unbelief in what he puts forward as positive statements, without good grounds. I do not for a moment doubt his veracity, but I do the opportunities he has had for making such inquiries with exactitude. I once engaged in such a series of experiments. I well know how difficult it is to arrive at safe and positive conclusions. I even went so far in the transcendentalism of youthful enthusiasm as to make efforts to ascertain if there was any proof of the wonderful effect to be obtained in increasing the powers of minute doses of rhubarb by prolonged trituration, but never succeeded in making one-eighth of a grain act as an aperient dose.

As to the statements of proof put forward by the writer,

such have been over and over again advanced by the homœopaths as to the positive effects of their globules. I am fully aware of the effects of minute doses of podophyllum, and yet I never could depend on a smaller dose than one-twelfth of a grain, and it is uncertain in any dose. But podophyllum is not rhubarb. It may be that in medicine we have to do with the "dura ilia messorum," but two grains of Barbadoes aloes are often given with perfect impunity; and the nicest and most careful prescriber I ever met, the late Sir H. Marsh, told me that he never could depend on less than one grain as an aperient dose; that when he gave smaller quantities, it often accumulated, and then acted too powerfully.—I am, Sir, yours respectfully,

J. W. MARTIN.

Portlaw, August 7, 1886.

P.S.—As controversies of this kind will not lead to much useful results, I will decline answering any further correspondence.

### SCALE FOR MAREY'S SPHYGMOGRAPH, AND REMARKS ON THE MODE OF PLACING THE INSTRUMENT ON THE ARM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am aware that attempts have been made to apply a scale to the sphygmograph, in order to ascertain the exact rate of the pulse, and the precise time occupied by each beat. Having been employed for some months past in making sphygmographic observations, I found great inconvenience in using a graduated card for the purposes above mentioned, owing to the difficulty of starting the instrument at an exact division of the scale. I conceived the idea of having a transparent scale constructed, which could be laid down upon the tracing after its removal from the sphygmograph. Mr. Stephen Yeates, of Yeates and Son, Grafton-street, has constructed such a scale for me, which I find answers its purpose admirably. As the slide of Marey's sphygmograph takes ten seconds to run its whole length, I have had the scale graduated so as to correspond with seconds and tenths of seconds (these, in the case of the instrument I use, correspond exactly with half inches and tenths of an inch). I have also had lines cutting those at right angles drawn the whole length of the sphygmographic scale, at the same intervals (twentieths of an inch), or double the intervals (tenths of an inch) of the vertical lines. The scale is drawn upon a thin slip of horn. By applying this scale to a sphygmogram, we convert the sphygmograph into an accurate sphygmometer. We can by the use of this little appliance ascertain exactly the rate of a pulse, far beyond what we could count by our unaided sense of touch (even up to 600!). We can ascertain the exact length of a single beat, state in figures the various deviations, or estimate its amplitude. Thus in a tolerably healthy pulse, of which I have a sphygmogram, the length of the beat is 0.7 of a second; its height (measured by distances corresponding with tenths of a second on the scale) 0.35; thus the whole beat may be represented by 0.70 × 0.35. In a rapid pulse (fifth day of typhus) the length of beat is 0.5 of a second; height, 0.2; whole beat, 0.5 × 0.2. In this case also the duration of the up-stroke is 0.1. In a slow pulse (counted 34 per minute), length of beat, 1.4 second; height, 0.3, &c. We might also in this way describe the variations in the dichrotism &c., avoiding the use of a diagram in the description of the pulse, and enabling the reader to lay down a curve (on a scale similar to the one used), representing the described pulse. Although I do not pretend that the scale I have described may not admit of improvement, yet I think this mode of using the instrument possesses some novelty, as well as interest, both from a scientific and practical point of view.

With regard to fixing the sphygmograph upon the arm, which seems to have been a difficulty to several beginners,

myself among the rest, after numerous trials, the arrangement I pursue, as the best, is the following: I place on the back of the arm a piece of thick, firm, yet pliable leather (six inches long, by three wide, rounded at the corners), in the centre of which is placed a strong hook. I place the sphygmograph in position, and pass the lace (which is composed of two yards of strong silk braid) over the leather and round the pins on the wings of the instrument, until the whole is firmly bound to the arm. I then give the lace a turn round the hook, next round the first phalanx of the thumb, again round the hook, and so on for all the fingers. I find it of particular importance to steady the thumb, as its tendon passing near the radial artery at the point where the instrument is applied, is very apt to interfere with the regular action of the spring. I cannot agree with those who recommend the use of elastic bands instead of an inelastic lace (as used by Marey), in tying on the instrument, or the use of a thick and soft pad for passing the lace over on the back of the arm. Both these arrangements tend to give elasticity to the attachments, allowing the pulse to communicate a slight motion to the whole instrument, and wasting some of the force which should otherwise have been expended on the mechanism of the essential part of the instrument. There should be no elasticity, if possible, except in the spring which presses upon the pulse.—Yours obediently,

THOMAS WRIGLEY GRIMSHAW, M.B.

13, Molesworth-street, August 10, 1866.

#### EXAGGERATED REPORTS OF CHOLERA, SOUTHAMPTON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The *Lancet* persists in feeding the daily papers with exaggerated statements in reference to the fatality of cholera at Southampton. I have just returned from the residence of the registrar, and learn that the aggregate deaths, from all causes, during the month of July, amounted to 140; those who had suffered from chronic disease, the aged, and infants, forming a large proportion, as is invariably the case when an epidemic sets in—the weakly yielding first—and that during the four days in the present month the decrease in the mortality has been very marked—only one or two from cholera daily.

You may observe that the 140 deaths during the month of July, with a population of nearly 50,000, is below the ordinary average of some of our thickly populated towns. Hence, what can the writer in the *Lancet* mean by asserting "that our mortality has been terribly great!" "The fearful mortality of the Southampton cases speaks for itself," &c.! The writer goes on to remark on "the removal of patients from localities of the most possible insanitary condition!"

The writing then becomes superfine: "Many cases have passed through the stage of cyanotic prostration, but these have for the most part terminated fatally, either from consecutive fever, prolonged somnolency, hæmatozic influences, or from the most painful and pathognomonic form of dyspnoea!"

The ice-bag puff is now considered a thing of the past—"indeed, unprejudiced observers think them worse than useless." "Stimulants retain some warm and successful advocates;" "the castor-oil treatment is most repugnant to the patients." "The hypodermic method of administering medicines is still thought and spoken of favourably,"—but surely not such acrid substances as corrosive sublimate and turpentine, which received last week's laudation!

Another part of the *Lancet* announces—"We find that drugs are still continued to be employed, of which ample experience has shown the utter futility, and which are only prevented from destroying life because, happily, they are not absorbed—because, that is, they do not enter the

economy [how explanatory], and cannot, therefore, act either for good or evil!"

Surely such writing, with much more that has recently appeared in the pages of the *Lancet* in reference to the inculcation of both facts and principles, cannot be accepted as representing the knowledge of our thoughtful and practical men, but rather strikingly depict the deplorable snobism of a section of the profession. The juvenile conductors of the *Lancet* owe their position to the untiring energy of an honest, strong-headed man. Let them take heed lest their gentility and effeminacy lose them that which they would certainly never have accomplished for themselves.—I am, Sir, yours faithfully,

EDWIN HEARNE.

Park Lodge, Southampton, August 4, 1866.

#### MEDICAL FEES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I wish to call your attention to a few facts connected with medical fees for attendance at Petty Sessions Courts. I was on last Tuesday summoned to attend the court here as medical evidence in some serious cases; I was obliged to remain from eleven a.m. until five p.m., and was called on to give evidence as to the state of three persons seriously injured. The parties inflicting the injuries were either sent to prison with hard labour or heavily fined.

After my six hours' attendance in court, I asked for an order for my fee, and was coolly told by the magistrates that I could get none, as the Castle authorities had sent a circular requesting that no order should be made for medical attendance, but that the dispensary doctor should, in all cases, be called on without fee. Now, as I happen not to be connected with any dispensary, I consider it a great grievance that I shall never in similar cases be entitled to a fee; and, if I refuse to attend, a warrant will be issued to compel me. Can you give me any information on this subject? Are medical men to be the slaves of attorneys and magistrates on such occasions? For from this it is certain that they can most unjustly compel any of us, at the expense of our private practice, to remain all day in a courthouse without any remuneration whatsoever.—I remain, dear Sir, yours truly,

J. W. DWANE, L.R.C.S.I., &c.

Cloyne, August 15, 1866.

X. X.—We cannot sacrifice any of the interest of the journal for the sake of an extra-professional circulation. The series of communications is, however, finished, and on another occasion the suggestion of our Correspondent will be borne in mind.

W. S., Dublin, shall have a private note.

#### BRITISH MEDICAL ASSOCIATION.

In this day's issue we publish Mr. Bowman's important Address in Surgery. In our next number we hope to give Dr. Hughes Bennett's Address on Medicine. The length of Mr. Bowman's valuable address has compelled us to postpone the publication of papers by Mr. Richardson, Dr. Madden, Mr. Macalister, Dr. MacCormac, and Dr. Griffith. We hope to give them in our next.

DEATH OF DR. RYAN.—We regret (says a Jamaica paper) in having to announce the death of Dr. Ryan, of H.M.'s steamer *Aboukir*, which occurred at Port Royal on Monday. The remains were brought up to this city yesterday, and in the afternoon interred at the West Burial Ground. The funeral procession left the Steam Company's Wharf at a quarter to six o'clock. The hearse was preceded by a firing party of marines, and the procession was formed of the ship's crew, followed by several naval and military officers, some in coaches and some on horseback, those of the highest rank following last.

## THE SANITARY ACT, 1866.

THIS Act, to which we have already, on two occasions, called public attention, contains provisions of so novel and so interesting a nature, that we think it right, especially at the present time, to give further prominence to some of its more important provisions. We propose to do this in a popular and easily intelligible form. Any person who wishes to take action under the Act should, of course, have recourse to and be guided by the very words of the Act itself.

Section 1 gives its short title—"The Sanitary Act, 1866." Its register number in the statute-book is the 29th and 30th of Victoria, chap. 90.

Section 4 gives power to any sewer authority (that is, as the case may be, the Town Council, or the Commissioners under a local Act, or the Vestry) to form a committee of its own members and others to act on its behalf.

Section 5 gives to the sewer authority in certain cases the power of forming any part of its district into a special drainage district, and of levying a rate for sewage purposes within such district.

Section 6 gives to any number of the inhabitants of such district (not being less than twenty) the power of appealing against the formation of such special drainage district to a Secretary of State, who, after due inquiry, may if he thinks proper, annul or modify the decision of the sewer authority.

Section 8 gives power to any owner or occupier within the district of the sewer authority to empty his drains in a proper manner into the drains of the sewer authority.

Section 9 gives power to any owner or occupier outside the district of the sewer authority, upon such terms as may be agreed upon; and in case of dispute, the matter is to be settled by two magistrates, or by arbitration.

Section 10 empowers the sewer authority to call upon any person living within 100 feet of any public sewer to make a drain from his house to the public sewer; if the distance is more than 100 feet, it may call upon him to empty his drains into a covered cesspool. If such person fails to comply, the work may be done by the sewer authority, and the expenses may be recovered in a summary manner.

Section 11 gives to the sewer authority power to supply its district with water by digging wells, making reservoirs, and doing any other necessary act.

Section 16 gives power to the chief officer of police within the district of any nuisance authority, by direction of a Secretary of State, to deal with nuisances, if the nuisance authority is proved to have neglected its duty.

The officer of police may not, however, enter any house for this purpose without either the consent of the occupier or a magistrate's warrant.

Section 19 adds to the list of legal nuisances—(1) any house or part of a house so overcrowded as to be dangerous to the health of the inmates; (2) any dirty, ill-ventilated or overcrowded factory or workshop; (3) any fireplace or furnace not consuming its own smoke, so far as is practicable.

Section 20 imposes upon the nuisance authority the duty of inspecting its district from time to time, with a view to the abatement of nuisances.

Section 22 gives power to the nuisance authority, in certain cases, to order an owner or occupier to cleanse and disinfect his house and anything in it, under a penalty of 10s. a day for disobedience; and allows the nuisance authority, in case of default, to do the work itself and recover the expenses from the owner or occupier. Where, in the opinion of the nuisance authority, the owner or occupier is unable, from poverty or otherwise, to cleanse and disinfect his house, it may, at its own expense, and with the consent of the owner or occupier, do the work itself.

Section 24 empowers the nuisance authority to maintain carriages for the conveyance to a hospital or to their own

homes of persons suffering under any contagious or infectious disease.

Section 25 exposes to a penalty, not exceeding £5, any person who, without notice to the owner or driver, enters any public conveyance while suffering under any dangerous infectious disorder. No owner nor driver need carry any such person without being first paid all losses and expenses.

Section 26 empowers any magistrate, under certain circumstances, to order the conveyance to a hospital of any person suffering under any dangerous contagious or infectious disease who is without proper lodging or accommodation, or lodged in a room occupied by more than one family, or who is on board any ship or vessel.

Sections 27 and 28 empower the nuisance authority to provide a proper place for the reception of the corpses of persons who have died of any contagious or infectious disease, and of corpses awaiting a post-mortem examination.

Section 29 empowers the nuisance authority, with the consent of the Privy Council, to make rules for removing to and keeping in a hospital any person arriving within its district in a ship or boat and suffering under a contagious or infectious disorder.

Section 30 extends the power of the nuisance authority in certain cases to ships and boats not lying within its district.

Section 35 empowers the nuisance authority in certain cases to make regulations for (1) limiting the number of persons who may occupy a house or part of a house which is let in lodgings; (2) the registration of such houses; (3) inspecting and cleansing such houses; (4) providing privies and other appliances and means of cleanliness for such houses, and for cleansing and ventilating the common passages and staircases; (5) cleansing and limewhiting such premises.

Section 36 provides for the temporary or permanent closing of such houses under certain circumstances.

Section 37 gives to the sewer authority (in the metropolis, to the nuisance authority) power to provide district hospitals or temporary places for the reception of the sick.

Section 38 exposes to a penalty not exceeding £5 any person suffering from any dangerous infectious disorder who wilfully exposes himself, without proper precaution against spreading such disorder, in any street, public place, or public conveyance, and to a like penalty the owner or driver of any public conveyance who knowingly conveys such sufferer and does not immediately afterwards provide for its disinfection.

Section 39 exposes to a penalty not exceeding £20 any person who knowingly lets a house or part of a house or a room in which any person suffering from any dangerous infectious disorder has been, without first having it and all articles therein disinfected to the satisfaction of a medical man.

Section 49. Where complaint is made to one of Her Majesty's principal Secretaries of State that a sewer authority or local Board of Health has made default in providing its district with sufficient sewers, or in the maintenance of existing sewers, or in providing its district with a supply of water in cases where danger arises to the health of the inhabitants from the insufficiency or unwholesomeness of the existing supply of water, and a proper supply can be got at a reasonable cost, or that a nuisance authority has made default in enforcing the provisions of the Nuisance Removal Acts, or that a local Board has made default in enforcing the provisions of the Local Government Act, the said Secretary of State, if satisfied, after due inquiry made by him, that the authority has been guilty of the alleged default, shall make an order limiting a time for the performance of its duty in the matter of such complaint, and if the said duty is not performed by the time limited in the order, the said Secretary of State shall appoint some person to perform the same, and shall by order direct that the expenses of performing the same, together with a reasonable remuneration

to the person appointed for superintending such performance, and amounting to a sum specified in the order, together with the costs of the proceedings, shall be paid by the authority in default; and any order made for the payment of such costs and expenses may be removed into the Court of Queen's Bench, and be enforced in the same manner as if the same were an order of such Court.

Section 52 brings outward-bound and coasting vessels within the provisions of the Quarantine Act, and of all orders issued by the Privy Council under that Act.

Section 53 exposes to a penalty 20s. per day any person who does not at proper intervals, after due notice, remove his manure and other refuse matter from mews, stables, or other premises.

Section 56 applies the first part of the Act and the water clauses of the Public Health Act, 1848, to Ireland.

Section 57 applies the second part to Ireland.

Sections 58 and 59 direct that the expenses shall be defrayed out of borough rates, or out of the poor rates, if a Board of Guardians.

Section 60 directs that penalties shall be inflicted under the Petty Sessions Act, 1851.

Section 61 substitutes the Lord Lieutenant as the authority in the place of the Secretaries of State and Privy Council in England.

Section 62 empowers the Poor-law Commissioners to issue regulations.

Section 63 directs all Poor-law Officers to aid the local authorities.

Section 64 incorporates the Dispensary Act with this Act.

Section 65 enables the guardians of any union to recompense any medical officer for services under the Act.

Sections 66, 67, and 68 direct that the Poor-law Commissioners shall make inquiry into the state of public health.

Section 69 repeals the former Nuisances Acts.

REGULATIONS AS TO THE PAY AND POSITION OF NAVAL MEDICAL OFFICERS.

Admiralty, July 12th, 1866.

My Lords Commissioners of the Admiralty having had under their consideration the rank, pay, and position of naval medical officers, are pleased, under the authority of her Majesty's Order in Council of 6th July, 1866, to establish the following regulations:—

1. Staff surgeons to be placed on a separate list, and promotion to that rank to be open to officers for distinguished or special service (although twenty years on full pay may not have been completed).

2. The whole time served on full pay as an assistant-surgeon to be allowed to qualify for the rank of staff surgeon, provided the examination for surgeon is passed before he completes ten years' service.

3. The pay of surgeons and staff surgeons to increase by periods of four years, instead of five years as at present.

4. In order to put naval medical officers on the same footing as army medical officers, in respect of allowances in hospitals at home and abroad, they are to receive the following money allowances in lieu of provisions for themselves and servants, and for fuel and light:—

|                                                        | At home.   | Abroad. |
|--------------------------------------------------------|------------|---------|
| Inspectors of hospitals ... ..                         | £54 ... .. | £130    |
| Deputy inspectors, staff surgeons, and surgeons ... .. | 35 ... ..  | 112     |
| Assistant-surgeons ... ..                              | 30 ... ..  | 108     |

All other allowances for provisions to cease.

In cases where medical officers draw provisions or fuel from public stores, they will be charged for the same at cost price.

5. The scale of travelling allowances, extra pay, lodging money, and compensation for losses, to be fixed for naval medical officers according to their relative rank with other naval officers.

6. In regard to cabins; to meet the requirements of the service it is necessary that the senior executive officer and the staff commander, or master, should have the cabins placed most advantageously for the performance of their special duties; with these exceptions, medical officers are to

have cabins according to their relative rank in the service. Cabins will be allotted to assistant-surgeons.

7. Staff surgeons to be placed on the same footing as commanders with regard to servants.

8. A staff surgeon to be appointed to all flag ships bearing the flag of a commander-in-chief on a foreign station, with an allowance of 5s. a day in addition to his established pay.

9. The periods of retirement by age to be fixed as follows:—Surgeons and assistant-surgeons at fifty-five years of age; staff surgeons at sixty years of age; inspectors-general and deputy inspectors-general at sixty-five years of age.

10. Assistant-surgeons at home, after completing their time for examination for the rank of surgeon, may be granted two months' leave of absence on full pay, on condition of their resuming their studies at a medical school or hospital.

11. To place staff surgeons on an equality in rank with surgeons-major in the army, they are to rank with commanders according to date of commission.

12. Staff commanders, secretaries to commanders-in-chief under five years' service, paymasters of fifteen years' seniority, and chief engineers of fifteen years' seniority, who now rank with staff surgeons, to rank with commanders according to date of commission.

13. Officers in command of her Majesty's ships must, on all occasions, whether on shore or afloat, be considered senior in rank and precedence to officers placed under their command. A ship must always be represented by an executive or combatant officer, after whom all officers are to take precedence according to their relative rank.

14. The pay of naval medical officers to be increased in accordance with the following scale:—

| RANK.                                             | Under 5 years' service. |     | Above 5 years' service. |     | Above 10 years' service. |     | Above 14 years' service. |     | Above 18 years' service. |     | Above 22 years' service. |     | Above 26 years' service. |     | Above 30 years' service. |     |
|---------------------------------------------------|-------------------------|-----|-------------------------|-----|--------------------------|-----|--------------------------|-----|--------------------------|-----|--------------------------|-----|--------------------------|-----|--------------------------|-----|
|                                                   | s.                      | d.  | s.                      | d.  | s.                       | d.  | s.                       | d.  | s.                       | d.  | s.                       | d.  | s.                       | d.  | s.                       | d.  |
| Assistant-surgeons                                | 10                      | 0   | 12                      | 6   | 15                       | 0   | 17                       | 6*  | ...                      | ... | ...                      | ... | ...                      | ... | ...                      | ... |
| Surgeons                                          | ...                     | ... | ...                     | ... | 17                       | 6†  | 20                       | 0   | 22                       | 0   | ...                      | ... | ...                      | ... | ...                      | ... |
| Staff surgeons                                    | ...                     | ... | ...                     | ... | ...                      | ... | ...                      | 24  | 0†                       | 27  | 0                        | 27  | 0                        | ... | ...                      | ... |
| Deputy inspectors-general of hospitals and fleets | ...                     | ... | ...                     | ... | ...                      | ... | ...                      | 30  | 0†                       | 32  | 0                        | 35  | 0                        | 37  | 0                        | ... |
| Inspectors-general of hospitals and fleets        | ...                     | ... | ...                     | ... | ...                      | ... | ...                      | ... | ...                      | 45  | 0†                       | 47  | 0                        | 50  | 0                        | ... |

15. Naval medical officers to be permitted to retire after twenty years' service on full pay, but the rate of half pay awarded to officers so retiring not to exceed five-tenths of the full pay to which they may be entitled from length of service.

16. As a special reward to officers of long and good service who, owing to the comparatively small numbers of the inspectorial ranks, have not been promoted to any higher position than that of staff surgeon, such officers of the rank of staff surgeon as have served for twenty-five years on full pay, to be allowed the half pay of £1 a day, on being compulsorily retired at sixty years of age, or on medical survey.

17. My Lords will consider, and publish hereafter, the manner in which it may be found most advisable to assist naval medical officers in their professional education after examination and admission into the navy.

The new scale of pay to come into operation on the 1st January, 1867; the other arrangements from this date.

By command of their Lordships,  
T. G. BARING.

To all commanders-in-chief, captains, commanders, and commanding officers of her Majesty's ships and vessels.

\* Provided he passes his examination before ten years' service.  
† Or on promotion.

It is very probable now that Parliament has been prorogued, that the Commander-in-Chief, not having before his eyes the prospect of some pertinent questions in the House of Commons, may think fit to do away with the old method of promotion in the Brigade of Guards, as noticed at the commencement of the present year.

REPORT ON THE HEALTH OF DUBLIN,  
FOR THE FOUR WEEKS ENDING AUGUST 11, 1866.

By E. D. MAPOTHER, M.D.,

MEDICAL OFFICER OF HEALTH.

THE mortality during the past four weeks has been very low, 397 deaths having been recorded by the Registrar-General against 479 during the previous four weeks, and 450 during the corresponding period in 1855; the rate was, therefore, 1 in 643, while it was 1 in 299 in London, and in Glasgow, 1 in 466. It has lately been often inferred that Dublin is superior in salubrity, from the calculation of one week alone, whereas the annual death-rate in some other cities (London, for instance) have for many years been lower than that of this city. In the dispensary districts the rates were as follows:—Summer-hill, 1 in 710; Coleraine-street, 1 in 729; Blackhall-street, 1 in 460 (or excluding deaths in the North Workhouse, 1 in 826); Meath-street, 1 in 337 (or excluding deaths in the South Workhouse, 1 in 559); High-street, 1 in 996; Peter-street, 1 in 783; and Grand Canal-street, 1 in 960. Zymotic diseases destroyed 83 persons, including 321 by fever, and 193 cases of that disease were admitted into the Cork-street and Hardwicke Hospitals from dwellings within the municipal boundary, especially from the neighbourhoods of Francis-street, Meath-street, Golden-lane, Church-street, and Beresford-street. Diarrhoea cannot be said to have been epidemic during the past month, but 15 fatal cases have occurred, against 28 in the corresponding period last year, and 14 in the preceding month. Cholera was imported from Liverpool on the 29th of July, in the person of Jane Magee. Up to this day (August 17th) 49 cases of the disease have been certified, and 6 other cases probably occurred, but from the mildness of some, and the neglect of medical advice during life in other instances, no positive opinion can be pronounced. Of the decided cases 7 were persons from Liverpool, 3 contracted the disease evidently from them, and the remainder may have suffered from the same importation, but the connexion cannot be traced with certainty. The outbreak has demonstrated that cholera is communicable, or "catching" (the words infectious and contagious are objectionable, because of the restricted sense in which they may be used). The deaths have been 25 out of the 40 cases, or 62.5 per cent., and of the remainder nine are still under treatment. The following are the localities in which the disease has appeared:—City-quay, Tennis-court, Poole-street, Usher's-court, Meath-street, Albert-place, Margaret-place, Mayor-street, Poolbeg-street, North Anne-street, Bow-street, Wellington-street, Plunkett-street, Aungier-street, Winetavern-street, Bridge-street, and Cooke-st. In the last-named street it could have alone been said to have been distinctly epidemic and to still linger. The preventive measures which were advised, and in nearly every case adopted, were—First, the summoning of medical aid (the dispensaries are available day or night). Second, the removal of the patient to hospital (Sir P. Dun's and the Meath on the south, and the Hardwicke and Mater Misericordie Hospital on the north side, are prepared to receive patients at all times, and convey them in special vehicles). The advantages of isolation in hospital over treatment in the homes of the poor may be learned from the fact, that no second case has occurred in any room after the first was removed, whereas in many instances the contagion has spread to several inmates when the first attacked was retained in the dwelling. Third, the disinfection of the premises, for which competent persons are stationed at the Corporation Stores, Winetavern-street, Hanover-street East, and North Brunswick-street, from six a.m. to ten p.m., to proceed at the request of any one concerned to disinfect with chlorine gas. Under Providence, such efforts have been highly successful, aided as they have been by low temperature, much wind, and a copious rain-fall, amounting to 1.65 inches during the past two weeks. The other preventive measures which I feel it my duty to unceasingly urge are—1. The establishment of a refuge for the family of the person seized. The disease has been already carried from house to house by the want of such provision. 2. The erection of a hot-air chamber, in which bedding, clothes, and rags of the persons attacked or imported from infected places in England may be purified without injury to fabric. 3. Avoidance of impure water, by closing superficial wells and pumps, guarding from contamination the canals and basins, and boiling before use the suspicious water with which we are now supplied. It is also surely the duty of those houseowners who have hitherto resisted the Corporation bye-laws to comply with sanitary improvements. Many of the houses in which cholera has appeared are so ruinous that demolition is the only remedy; and it may be remarked that nearly every one of them would have been removed if the connecting railway scheme had been carried out. Many other circumstances of the epidemic are reserved for a future account. Consumption caused 57 deaths. The Inspector of Nuisances and his assistant directed the cleansing of 203 premises complained of at the City Hall, or in which communicable diseases had arisen. The nine sanitary sergeants inspected 93 nightly lodging-houses, 104 slaughter-houses, 3 knackers' yards, and 56 bakehouses. They also visited 2012 houses set in tenements, and found that 3472 sanitary defects previously noticed had been remedied.

Dr. SIBSON has been elected President of the British Medical Association in the room of the late Sir C. Hastings.

ARMY MEDICAL DEPARTMENT.

THE Director-General of the Army Medical Department presents his compliments to the Editor of THE MEDICAL PRESS AND CIRCULAR, and begs to enclose a List of the Candidates of her Majesty's British Medical Service who were successful at the Competitive Examination in March last, and who have passed through a course at the Army Medical School, showing the combined results of the examination.

Army Medical Department, August, 1866.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE twenty-second anniversary meeting of this important professional body was held last week in the rooms of the Royal Society, Princes-street, Edinburgh, under the presidency of Dr. Browne, Commissioner in Lunacy for Scotland, and formerly the able resident physician of the Crichton Institution for the Insane at Dumfries. The meeting was very largely and influentially attended, nearly fifty physicians engaged in the treatment of the insane having been present, the representatives of their speciality in England, Ireland, and Scotland, and even some physicians from the United States of America. Amongst those present were Drs. Tuke, Munro, Maudsley, Webster, London; Dr. Sherlock, Worcester; Dr. Arlidge, Newcastle-under-Lyme; Dr. Saxekey, Hanwell; Dr. J. F. Duncan, Dublin; Dr. Stewart, Belfast; Dr. J. Crichton Brown, Wakefield; Sir James Cox, M.D., Edinburgh; Dr. Skae, Morningside, Edinburgh; Dr. L. Lindsay, Perth; Dr. Jameson, Aberdeen; Dr. Butler, Hartford, Connecticut, U.S.A.; Dr. Gilchrist, Dumfries; Dr. Robertson, Hayward's Heath, Sussex. The President's address on the occasion was in the highest degree interesting, and listened to by his learned auditory with the most marked attention. In it he took a rapid survey of the advances and improvements in the treatment of insanity, and in the institutions set apart for its unhappily afflicted subjects, showing what a large amount of ability, humanity, and untiring perseverance was in active operation for ameliorating so serious a dispensation; and what great claims those engaged in so god-like a mission had for support and encouragement from all who had it in their power to afford the same. Several papers were afterwards read, and freely discussed, amongst them "The Insane Colony of Gheel," "The Effects of the Present System of Prison Discipline on the Body and Mind," "Asylum Architecture," &c., &c. The Association afterwards dined together at Stacey's Hotel, St. Andrew's-square, in the magnificent dining-hall of which a splendid and *recherché* entertainment was provided, and, amongst other visitors invited and present on the occasion, were Sir James Simpson, Bart., M.D.; Sir James Cox, M.D.; Sir John Wauchope, Bart., Chairman of the Lunacy Board in Scotland; the Presidents of the Colleges of Physicians and Surgeons, Edinburgh, &c. &c. The next meeting was fixed to take place in London under the presidency of Dr. Lockhart Robertson, the Physician Superintendent of the Sussex County Asylum for the Insane.

RICHARDSON'S ether spray producer is now being used in cases of parturient hæmorrhage.

## PROGRESS OF THE CHOLERA.

A CONSIDERABLE diminution has taken place in the number of deaths since our last report. In the week ending August 4, 1407 deaths from cholera and diarrhoea swelled the London mortality to 2661, the average for the corresponding week being only 1395. The deaths from cholera alone in that week rose to 1053 against 904 of the previous week. A disposition to spread was also noticed, although the force of the epidemic was spent on the eastern districts, in which 916 of the deaths took place.

From this time the mortality decreased, and the last return of the Registrar-General for a complete week is up to August 11. From his return we gather that there were 52 deaths less per day in London, and that the whole of the decreasement was due to the fall in the deaths from cholera and diarrhoea. Yet these two diseases carried off during the week 1045 persons, of which 781 died from cholera, and the remaining 264 from diarrhoea. This brings the total numbers for the five weeks during which the epidemic has prevailed to 3116 deaths from cholera, and 1338 from diarrhoea. Out of these, 3182 deaths occurred in the eastern district of the metropolis. From this day the decline has been maintained, as shown by the daily returns, which are now issued; for while on Saturday, the 11th August, 94 deaths were registered, the total for Sunday and Monday, the 12th and 13th, only reached 139. On Tuesday there were 77 deaths. These numbers do not include deaths from diarrhoea, which numbered on Sunday and Monday together 46, and on Tuesday 28. On Wednesday last, August 15, there were registered in London 61 deaths from cholera and 32 from diarrhoea. Of these, 49 from cholera and 16 from diarrhoea occurred in the Eastern District.

It is this concentration in the East that has directed so forcibly the attention of the Registrar-General to the water supply of this district. The East London Water Works have vindicated their water as might have been anticipated, from the imputation of conveying the poison, but we cannot overlook the fact that the field where the epidemic rages is just that supplied by this company. The water bears the test of chemical analysis, but how much may fail to be detected by our most careful scrutiny. We hope to see at once carried out the excellent suggestion of Dr. Frankland, that the companies should filter their water through animal charcoal. In the meantime it would be mere ordinary precaution to empty and disinfect every water-but and cistern.

Although the epidemic has declined in London there is a great disposition to spread, and fears must be entertained of a general visitation throughout the country. Already it is in the valley of the Thames. Last week several persons died of cholera at Weston-green, near Thames-Ditton, and cases have been reported from several sea-side places and inland towns.

In Liverpool there were 126 deaths in the week ending August 11.

Cases have occurred on the west coast of Scotland.

From Paris we hear that the disease is on the increase, but all official information is withheld. It has also appeared in many of the departments of France. At Amiens and Marseilles it is said to be on the decline. In Belgium it appears to increase, while in Holland it is diminishing. A very malignant form has appeared on the lower Danube. Number of cases have occurred in

the Prussian and Austrian armies. In St. Petersburg 2194 persons had died up to the end of July, and in other parts of Russia it is also prevailing.

**THE CHOLERA FUNDS.**—A very large sum of money is being subscribed for the benefit of the poor suffering from cholera. In about a fortnight the special fund of the Metropolitan Visiting Association, in response to an appeal by the Bishop of London, reached the sum of £10,000. The appeal on behalf of the London Hospital will produce at least £20,000, and thereby make up for the deficiency caused by the postponement of the ceremony of opening the new wing, to which we alluded some time since. The Mansion-House Committee, of which the Lord Mayor is President, are receiving money at the rate of about £1000 a day. Mrs. Gladstone's proposal to establish a home for the orphans of those who have perished from the pestilence is also being warmly supported, and numerous are the charities which are appealing (and not without response) for extra funds to be able to afford a larger aid. If we have not the knack of preparing for these times, and regulating our local government with a view to sanitation, we may at least be grateful that in England the cry of the poor and suffering for help from the rich is never heard in vain. The noble workers of our own profession must feel encouraged by these proofs that those who cannot give skill are ready to contribute of that which they have.

**OUR LOCAL BOARDS.**—Now that the danger has come home to them, the authorities, who have so long resisted the measures proposed by sanitary authorities, are displaying a commendable diligence. In every direction the drains are being flushed with disinfectants. The smell of carbolic acid is becoming very familiar to the pedestrian in the streets of London. House-to-house visitation is being organized in many districts. If every drain, water-closet and water-but were thoroughly cleansed and disinfected, the result could not fail to be beneficial. Now, before the public fear subsides, is the time to insist on these important measures. No greater error could be committed than to relax any efforts on the strength of a slight decrease in the mortality. It is the especial duty of all local authorities to provide for more complete scavenging, and for the prompt removal of all accumulations of filth. We would draw attention to the dust-bin, which in London houses receives all the waste of the kitchen. Its contents are often permitted to remain in a decomposing state for many days. Nothing could be easier than to arrange for the daily removal of this offensive mass. If our Continental neighbours throw their rubbish into the street, a cart passes to collect it and take it away, at least once in the twenty-four hours. If we dislike making the street a temporary receptacle we need not therefore hinder the daily call of the dust-man.

## CHOLERA NOTES FROM ABROAD.

DR. CALVY, the Senior Physician to the Civil Hospital at Toulon, who has had considerable opportunities of studying cholera during its recent visitation of that city, closes a paper "On the Contagiousness of Epidemic Cholera," published in *L'Union Médicale*, with the following conclusions:—

- "1. Cholera morbus is transmissible and importable—that is to say, contagious.
- "2. Wisely organized quarantine is necessary to prevent its invasion by the sea.

"3. It is all the more important to organize these sanitary measures in a sufficiently efficacious manner, and to rigorously enforce the practice of them as often as there may be need, since the political journals announce a new invasion of cholera among the pilgrims at Mecca, from whence undoubtedly the epidemic of 1865 originated.

"4. This quarantine would be the necessary completion of the preventive measures ordered in the East for this year by the Sanitary Congress which met at Constantinople, in consequence of the laudable and salutary initiative of the French Government.

"5. It is true the population would not be protected by the quarantine from the malady, when, in place of threatening from the sea, it should advance across the Continent; but one may assert with the greatest reason, that if the disease has two gates of entrance, and the one through which its approach is the more rapid, more easy, and more often chosen, be closed against it, the danger will be very considerably diminished, although it cannot be completely overcome."

**CONTAGIOUSNESS OF CHOLERA.**—In the report of Dr. Rochard on the epidemic which visited the East and neighbouring places from November, 1865, to March, 1866, there is a curious fact concerning its importation to the little Island of Groix, which by reason of the position of this island acquire especial interest. On the 16th of last February, when there was no case of cholera in the island, a fishing boat landed a young sailor, 22 years of age, who came from Croizic where he had contracted the disease. This man was conveyed to his family at the village of Kerillo; at the end of ten days, when he was convalescent, his mother, who had not quitted him an instant, was attacked in turn and died on the fourth day. Twelve hours after the death of the mother of the young sailor an old woman who had nursed her up to her death also fell ill of cholera, and was carried off in two days; an infant in the neighbourhood died the same day. Finally, the little hamlet of but 130 inhabitants had a reckoning for itself alone of twenty-five cases of cholera with nine deaths, while the rest of the island only registered six cases and a single death.

#### ROLLS COURT.—JULY 30.

##### WALLACE v. THE ATTORNEY-GENERAL.

It will probably be remembered that this suit arose out of a bequest by Lord Henry Scymour, of a large sum of money to "*les hospices de Londres et de Paris.*" The question what was meant by the word "*Londres*" in the bequest, was originally argued, and subsequently this Court was occupied for several days in listening to arguments on behalf of numerous charitable institutions in London, which claimed to be entitled to participate in the above bequest by virtue of the term *hospices*. His lordship then decided that only such charities were entitled to participate as gratuitously received persons who required relief on the ground either of age and poverty, or of youth and neglect, or of mental alienation, or of incurable disease. It was then referred to the chief clerk to apply the test of this definition to the various claimants. The chief clerk made his certificate disallowing the claims of the London hospitals (commonly so called), and of several other charitable institutions. These all now appealed to the judge from the decision of the chief clerk, and their claims were consecutively argued. Grouping the London hospitals into one class, his lordship simply confirmed his decree as against them. As to the other institutions, the names of which are given underneath, his lordship at once dismissed the claims of the Brompton Hospital, St. Luke's, the House of Charity, Soho, the London Female Penitentiary, and the Guardian Society. His lordship reserved till to-morrow his judgment as to Bridewell, Bethlehem Hospital, the Convent in Carlisle-place, Westminster, the Governnesses' Benevolent Institution, the Catholic Almshouses at Chelsea, and the British Asylum for Deaf and Dumb Females.

At the late competitive examination of candidates for commissions in the medical department of her Majesty's army there were only twenty-eight candidates, whilst the vacancies considerably exceed that number.—*Lancet*.

#### NOTICES TO CORRESPONDENTS.

*Mr. Griffin.*—The letter is inserted.

*Dr. J. W. Ogle.*—The paper has been received.

*The Army Medical Department.*—The list has been received.

*J. H. B.*—In our next.

*Dr. F.*—The paper mentioned has not come to hand.

*Medicus.*—Your supposition is well founded.

*F.R.S.* shall receive private note.

## Medical News.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following Members of the College, having been elected Fellows at previous meetings of the Council, were admitted as such on the 9th inst. :—

Blades, William Dawson, L.S.A., Kirkby Stephen, Westmoreland; diploma of Membership dated August 4th, 1840.

Carter, Charles Henry, L.R.C.P.E. and L.S.A., Pewsey, Wilts; December 13th, 1839.

Hall, John Charles, M.D. Edin., Sheffield; January 11th, 1839.

Smith, Henry, her Majesty's Indian Army; July 7th, 1837.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.**—The following gentlemen have since the 1st of last April passed the examination in General Education :—

Townson Ashburner, Lancashire; James H. Bogle, South Wales; D. Blair Brown, Glasgow; Duncan Brown, Comrie; Henry William Drew, Cape of Good Hope; Andrew Lyall; Henry Mackenzie, Edinburgh; William Mackie, Glasgow; D. E. Mills, Nottingham; Geo. Campbell Naismith, Sultanpore, Oude; George Robathan, Monmouthshire; David Sime, Wick; John Somerville, Moffat; John Souter; William Day Stewart, Madras; Daniel Sutherland, Wick; Francis Perley Taylor, New Brunswick; Francis Vacher, London; P. M. Vaughan, Cheshire.

During the recent sittings of the examiners, the following gentlemen passed their final examinations, and were admitted L.R.C.P. and L.R.C.S. :—

|                                    |                                    |
|------------------------------------|------------------------------------|
| Bookless, James Pitcairn, Kelso.   | Fergusson, J., Kirkcudbrightshire. |
| Bowie, John, Edinburgh.            | Kerr, J. A. Cochrane, Edinburgh.   |
| Brass, Joseph Traill Watt, Orkney. | Little, John Fletcher, Kilkenny.   |
| Brown, Henry, Belfast.             | Maher, Nicholas, Thurles.          |
| Chisholm, William, Edinburgh.      | Meehan, James, Limerick.           |
| Cribbes, Henry Scott, Perthshire.  | McGann, Terence Joseph, Clare.     |
| Dolan, Thos. Michael, Tipperary.   | McInterson, A. McMaster, Madras.   |
| Dutt, Omesh Chander, Calcutta.     | Sandham, William Sale, Cork.       |
| Fearon, Thomas, Warrenpoint.       | Stewart, William Day, Madras.      |

The following passed their first professional examinations during the July and August sittings of the examiners :—

Francis Vacher, London; William T. Limrick, Cork; William Knox, Tyrone; Theobald M. Bryson, county Londonderry; James L. Dingwall, Glasgow; George Stanley Elliot, Exeter; William Thomson, Edinburgh; David Scott, Park, Hawick; John Wilson, Edinburgh; James Stuart, county Cavan; Thomas Todhunter, Whitehaven; Orssen Beamish, Clonakilty; James B. N. Kane, Kilkenny; Richard Windele, Cork; Thomas M.-W. Ahearne, Cork; John Jennings, County. Cork.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 9th :—

Croft, John Henry, Guy's Hospital.  
Eagleton, Joseph, Wolverhampton.  
Hayden, James Augustus, High Wycombe.  
John, William, Haverfordwest.  
Keall, William Powell, Bristol.  
Kingston, Joseph Lindsay, Barking-road, Canning-town.  
Moore, George, Birmingham.  
Phillips, James Mathias, Taibach, Glamorganshire.  
Pollock, Robert, Loudsale, Paisley.  
Salzmann, Frederick William, Brighton.  
Watson, George Samuel, St. Marylebone Infirmary.

The following gentlemen also on the same day passed their first examination :—

Carré, Louis C. A., Guy's Hospital.  
Duke, Joshua, Guy's Hospital.  
Parkinson, Edmond W., St. George's Hospital.  
Sewell, Allen, University College.

**ROYAL COLLEGE OF SURGEONS, EDINBURGH.**—The following gentlemen were admitted Fellows of the College on the 2nd inst. :—

Carmichael, William Scott, Edinburgh.  
Manford, Robert Alexander, Inverness.  
White, Joseph, Nottingham.

The following passed their final examinations and were admitted Licentiates of the College during the July sittings of the examiners :—

|                                    |                                                    |
|------------------------------------|----------------------------------------------------|
| Balfour, William Green, Montrose.  | McNicol, John Clark, Argyllshire.                  |
| Campbell, Chas. Moss, Cawnpore.    | Moore, Joseph H., Downpatrick.                     |
| Fitzgerald, R. Gerald, Co. Carlow. | Muir, John Stuart, Leith.                          |
| George, John, Carrickfergus.       | Power, Robert Vincent, Cork.                       |
| Gordon, James, Perthshire.         | Taylor, Francis Perley, St. John's, New Brunswick. |
| Kingston, Thomas, Co. Cork.        |                                                    |

**UNIVERSITY OF ABERDEEN.**—During the past year

the following candidates, after the usual examinations, have received degrees in Medicine and Surgery :—

The following candidates received promotion to THE DEGREE OF M.D.

- |                                    |                                    |
|------------------------------------|------------------------------------|
| Atkinson, F. P., Kew, Surrey.      | Manson, Patrick, Aberdeen.         |
| Colborne, A. C. London.            | Murray, James, Aberdeen.           |
| Dawson, John, Yarmouth, Norfolk    | Ogston, Alex., Aberdeen.           |
| FitzPatrick, W. Honner, Liverpool  | Saunders, C. E., Cuckfield Sussex. |
| Fowler, John Smith, Aberdeen.      | Smith, James Dear, Mayo.           |
| Gray, Alex. Biddoch, Aberdeen.     | Snaith, Frs. Boston, Lincolnshire. |
| Knox, John, Radkewell, Derbyshire. | Strange, Wm. Heath, London.        |
| McClintock, John Robt., Perth.     |                                    |

And the following candidates, after the usual examinations, received degrees in Medicine and Surgery :—

THE DEGREE OF M.B.

- |                                    |                                                   |
|------------------------------------|---------------------------------------------------|
| Aitken, Wm. Scott, Greenock.       | McDonald, W., Cromdale, Morayshire.               |
| Atherstone, E., Cape of Good Hope. | McEwen, Donald, Forres.                           |
| Attygalle, John, Ceylon.           | McRae, Alex. Edward, Aberdeen.                    |
| Carbery, Joseph, Calcutta.         | Moir, Douglas, Aberdeen.                          |
| Carter, R., Newbury, Berkshire.    | Morgan, L. Wayne, Pontypridd, Glamorganshire.     |
| Davidson, Alex. Dyce, Aberdeen.    | Nicolson, David, Aberdeen.                        |
| Edgelow, G. Teignmouth, S. Devon.  | Phillips, James Mathias, Tarbach, Glamorganshire. |
| Freeman, A. J., Southsea, Hants.   | Rayner, Henry, Hythe, Kent.                       |
| Gibbes, John M., Sidmouth, Devon.  | Tibbitts, Robert William, Bristol.                |
| Gordon, Wm. Robert, Banffshire.    | Tidy, Charles, Meymott, Hackney.                  |
| Graham, Benjamin, Morayshire.      | Wadd, Frederick John, London.                     |
| Grant, Robert, Banffshire.         | Will, John C. Ogilvie, Aberdeen.                  |
| Hocken, Charles Edward, London.    | Williamson, James, Aberdeen.                      |
| Keith, Joseph Forbes, Aberdeen.    | Wills, Charles James, Brighton.                   |
| Lethbridge, Alfred S., Devon.      | Whyte, John, Culaird, Inverness.                  |
| Lupton, Richard John, Bradford.    | Yates, James, Oldham, Lancashire.                 |
| Maconachie, George, Forgue.        |                                                   |
| Macrae, Wm., Stornoway.            |                                                   |
| Macrobin, Andrew A., Aberdeen.     |                                                   |

THE DEGREE OF C.M.

- |                           |                          |
|---------------------------|--------------------------|
| Aitken, William Scott.    | Manson, Patrick.         |
| Atherstone, Edwin.        | McDonald, William.       |
| Birnie, William Sharp.    | McEwen, Donald.          |
| Carbery, Joseph.          | McRae, Alexander Edward. |
| Davidson, Alexander Dyce. | Moir, Douglas.           |
| Edgelow, George.          | Morgan, Lewis Wayne.     |
| Gilbes, John Murray.      | Nicolson, David.         |
| Gordon, William Robert.   | Phillips, James Mathias. |
| Graham, Benjamin.         | Rayner, Henry.           |
| Grant, Robert.            | Tidy, Charles Meymott.   |
| Keith, Joseph E.          | Wadd, Frederick John.    |
| Lethbridge, Alfred S.     | Will, John C. O.         |
| Lupton, Richard J.        | Williamson, James.       |
| Maconachie, George.       | Wills, Charles James.    |
| Macrae, William.          | Whyte, John.             |
| Macrobin, Andrew Arthur.  | Yates, James.            |

Of the above-mentioned Candidates—

William Scott Aitken, Alex. Dyce Davidson, Wm. Macrae, Henry Rayner, and Charles Meymott Tidy, received their degrees in Medicine and Surgery with Highest Academical Honours ;

George Edgelow, Andrew A. Macrobin, Donald McEwen, David Nicolson, James Williamson, and John Whyte, received their degrees in Medicine with Academical Honours.

James Yates

received his degree in Surgery with Academical Honours.

At the same time,

John Thomas Hughes

was certified as having passed all the examinations, and is entitled to receive his degrees on attaining the necessary age.

And at the late graduation term, the following were declared to have passed part of their examinations :—

- Alfred Henry Antonisz, John Arthur, Charles Bennett, Henry C. Buckley, James Cameron, James C. G. Carmichael, James Allan Coult, Geo. A. Craig, John M. Crombie, James Trigue Crowden, Frederick Adams Davson, Alex. G. Duncan, James Farquhar, Alexander Forbes, Robert Grant, James Ironside, Alex. Hunter Mair, Charles M. Matthew, Robert G. McCallan, James F. P. McConnell, John Sturrock Mitchell, Alex. Reid, John Robb, Geo. Robertson, David Shirres, George Alex. Simpson, Joseph H. Smith, John L. Thomas, David Tulloch, William Abram Walker, Richmond C. Willock, Henry Wm. Williams, Alexander G. Wood.

WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING AUGUST 18TH, 1866.

By J. H. STEWARD, Strand and Cornhill, London.

| Aug. 1866. | Barometer reading reduced to 32 degrees. | Thermometer. |       | Dry bulb. | Wet bulb. | Wind.      |        |       | Remarks. |

Appointments.

- J. B. ALLEN, L.K.Q.C.P.I., has been elected Coroner for the county of Wexford.
- R. BARWELL, F.R.C.S.E., has been appointed Lecturer on Anatomy at the Charing-cross Hospital, vice E. Canton, F.R.C.S.E., resigned.
- W. J. COULSON, F.R.C.S.E., has been appointed Assistant-Surgeon to St. Mary's Hospital, vice H. Walton, F.R.C.S.E., appointed Surgeon.
- Dr. EGAN, L.K.Q.C.P.I., has been elected Medical Officer and Public Vaccinator for the No. 1 or Fulham Town District of the Fulham Union, vice W. E. Wright, M.R.C.S.E., resigned.
- Dr. HADDEN of Tetford, has been elected Medical Officer and Public Vaccinator for the Tetford District of the Hornacastle Union, Lincolnshire, vice R. P. Tiekler, L.R.C.P.Ed., resigned.
- J. C. HALL, M.D., has been re-elected a Physician to the Sheffield Public Hospital and Dispensary.
- W. C. HOFFMEISTER, M.D., has been elected Medical Officer for the Cowes District of the Isle of Wight Union, vice J. E. Gibson, M.R.C.S.E., resigned.
- R. L. JORDISON, M.R.C.S.E., has been elected Medical Officer for District No. 5 of the Romford Union, Essex, vice J. J. Macaldine, M.D., resigned.
- E. A. KEOGH, M.D., has been elected Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Castleblayney Dispensary District of the Castleblayney Union, vice Ashe, resigned.
- D. KNOX, M.D., has been elected Medical Officer and Public Vaccinator for the Scrooby District of the East Retford Union, vice J. J. Johnstone, M.D., resigned.
- J. LAW, M.D., has been re-elected a Physician to the Sheffield Public Hospital and Dispensary. Dr. Law has also been appointed Physician to the Sheffield General Infirmary, vice C. Thompson, M.D., resigned.
- E. LLOYD, M.R.C.S.E., has been elected Medical Officer and Public Vaccinator for No. 1 or South District of the Llandilofaur Union, Carmarthenshire, vice H. Davies, M.R.C.S.E., resigned.
- J. McDONNELL, L.R.C.P.Ed., has been elected Medical Officer, Public Vaccinator, and Registrar of Births, &c., for the Dunmore Dispensary District of the Glennamaddy Union, Co. Galway, vice W. E. Donelan, M.R.C.S.E., resigned.
- Dr. OPPELT, L.R.C.P., of Great Russel-street, W.C., has been appointed Physician to the City Dispensary.
- S. PARKER, M.R.C.S.E., Surgeon to the Sheffield Public Hospital and Dispensary, has been appointed Surgeon to the Sheffield General Infirmary, vice H. Jackson, F.R.C.S.E., resigned.
- G. PARKINSON, M.R.C.S.E., Fell. Odont. Soc., has been appointed Dentist to the Charing-cross Hospital, vice Roberts, resigned.
- F. W. PARSONS, M.R.C.S.E., has been elected Medical Officer and Public Vaccinator for the Islip District of the Bicester Union, Oxfordshire, vice J. F. Sydenham, L.S.A.L., deceased.
- C. C. RICHARDS, M.D., M.R.C.S., has been appointed Medical Officer and Vaccinator to the Bethnal-green Union.
- R. H. SEMPLE, M.D., has been appointed Physician to the Eastern Dispensary, Leman-street, Whitechapel, vice S. H. Ward, M.D., resigned.
- C. VINES, M.R.C.S.E., has been elected Medical Officer and Public Vaccinator for the St. Lawrence District of the Reading Union, vice T. L. Walford, M.R.C.S.E., resigned.
- S. WOODMAN, L.R.C.P.L., has been elected Surgeon to the Ramsgate and St. Lawrence Royal Dispensary.

Vacancies.

- Gloucester County Asylum—Junior Assistant Medical Officer.
- Hereford General Infirmary—House-Surgeon, vice Mr. Walker, resigned.
- Metropolitan Free Hospital, Devonshire-square, City—Dental Surgeon
- Westham, Stratford, and South Essex Dispensary—House-Surgeon.

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

BIRTHS.

- On the 17th of June, at Cradock, Cape of Good Hope, the wife of George Grey, M.D., F.G.S., of a son.
- On the 5th inst., at Pentonville-road, the wife of E. H. May, M.R.C.S.E., of a daughter.
- On the 13th inst., at Queen's-road, Dalston, the wife of G. Sykes, M.D., of a daughter.
- On the 13th inst., at The Poplars, Twickenham-common, the wife of Martindale C. Ward, M.D., C.M., M.R.C.S.E., &c., of a daughter.
- On the 14th inst., at Ashville-place, Batterssea-park, the wife of W. Greenwood Sutcliffe, M.R.C.S.E., of a son.
- On the 14th inst., at Kew, the wife of Chas. Wm. Browne, M.R.C.S.E., of a daughter.

MARRIAGES.

- On the 31st ult., at St. George's, Hanover-square, F. G. Reed, M.D., of Hertford-street, May-fair, to Laura Ann, widow of Mons. de Salignac.
- On the 9th inst., at Tiverton, Devon, Frederick Steuart Colquhoun, Surgeon, of Knutsford, Cheshire, to Margaret, daughter of the late J. Cartwright, Esq.

DEATHS.

- On the 8th ult., Eugene A. Kingsley, M.R.C.S.E., of Wooton-under-Edge, aged 33.
- On the 10th ult., at St. Leonard's-on-Sea, N. L. Young, M.D., of the Island of Barbadoes, West Indies, aged 75.
- On the 3rd inst., at Carnew, county Wicklow, G. A. F. Halahan, M.D.
- On the 7th inst., at Parson-street, Glasgow, Hugh Rea, L.F.P. & S., Glas.

WESTMORELAND LOCK HOSPITAL,  
TOWNSEND-STREET.

**Wanted a fit Person to fill the Office of**  
Surgeon-Apothecary, to reside on the premises, at a salary of £75 a year, with Furnished Apartments, Coals, and Light. The Gentleman appointed must be a Licentiate Apothecary, Surgeon, and Accoucheur.

Testimonials to be sent in before the 1st SEPTEMBER. Candidates to attend at Two o'clock the 1st September. The Election will be held on the following Saturday.

Further information upon application to the Registrar, at the Hospital.

**James's Fever Powder, 4s. 6d. per bottle;** packets 2s. 9d. each.

Prepared and sold by J. L. KIDDLE, 31, Hunter-street, Brunswick-square, London.

This Preparation has been so extensively employed by the Faculty, and its merits so universally acknowledged by the public at large, as to render all further remark on the part of the Proprietor unnecessary. To be had of all Wholesale Druggists.

**DR. EVANS begs to submit to the notice of the Profession the Red Gum of the**

"EUCALYPTUS ROSTRATA"

of Western Australia, as an Astringent in Diarrhoea, Dysentery, &c., in doses of 15 to 20 grains.

Also Lozenges prepared from it, for Loss of Voice, &c.

CARBOLIC LOZENGE,

(Prepared from Carbolic Acid), for giving relief in Asthma and Bronchitis, as well as in the Sore Throats of Diphtheria and Scarlet Fever.

EMOLLENT SUPPOSITORIES,

In habitual Constipation these Suppositories have been found not only serviceable but effectual in restoring the peristaltic action of the Bowels, thus obviating the necessity of continually resorting to purgatives. In Hemorrhoids they afford much relief. There are three sizes of them—

PARVA. MEDIA. MAGNA.

Alocine, Tamin, Morphia, Belladonna, can be added, if so desired by the Practitioner.

EVANS' BLACK DROP,

Freed from Narcotina, a bitter analogous to Quinia, and freed from Thebaina, a stimulant analogous to Strychnia. One minim is equal to three of Laudanum.

The preparation so long known as *Braithwaite's* or the *Quaker's Black Drop*, having become extinct by the death of the maker, and no other preparation now obtaining the confidence of the Profession to the same extent, J. EVANS begs to submit to their notice his Drops, by the name of "Gutte Nigra, Evans," for which he solicits a trial, and their judgment.

A few Testimonials are annexed, which are expressive of the judgment of several Physicians who have given it extensive trial both in private and hospital practice:—

"Dublin, Rotunda Hospital, 29th September, 1865.

"I have extensively tried a new preparation of Black Drop, sent to me by Dr. J. Evans, of Dawson-street. I consider it an excellent anodyne, free from many of the disadvantages of common Laudanum, and quite equal in power to the former preparation so long known by the same name, but no longer in use.

"JOHN DENHAM, M.D., L.R.C.S.I., Master."

"Dublin, 9, Merriion-square, North, 27th October, 1865.

"I have ordered the preparation of Opium (Black Drop), made by Dr. Evans, of Dawson-street, with very great advantage. It seems to agree with patients better than those opiates which have been so long in the hands of the profession, by not causing sickness of stomach or uneasy sensations of the head. It is very satisfactory as a powerful sedative. I have used this medicine freely in Stevens' Hospital and in private practice.

"S. L. HARDY, M.D.,

Physician-Accoucheur to, and Lecturer on Midwifery and Diseases of Women and Children, Stevens' Hospital; Physician to the Institution for Diseases of Children &c."

"14, Harcourt-street, Decemb 18th, 1865.

"I have given full trial to a new preparation of Opium, designated 'Black Drop,' forwarded to me some time since by Dr. John Evans, of Dawson-street. I had been in the habit of using the former preparation known by that name, so long as it could be procured; and I feel no hesitation in expressing my conviction that Dr. Evans' preparation fully equals, in all respects, that admirable anodyne.

"JOHN RINGLAND, M.D., T.C.D., M.R.I.A.,

Fellow of the King and Queen's College of Physicians of Ireland, Senior Master of the Coombe Lying-in Hospital, Professor of Midwifery in the Ledwich Medical School."

THE INSPISSATED JUICE

OF

**Leontodon Taraxacum, or Dandelion.**

NOTE—This extract possesses all the remedial properties contained in the fresh root of the Dandelion, being a concentration, at a reduced temperature, of all its constituents.

Dr. Wilson Philip writes—"Of all means which I have employed to promote a regular and healthy secretion of bile, I have found none equal to Dandelion."

Dr. James Johnson ranks it amongst those agents that possess the power of preventing the formation of biliary concretions by keeping up a due and healthy secretion in the liver.

LABORATORY—49, DAWSON-STREET, DUBLIN.

Sold by REW & CO., 292, Regent-street, London.

**Mr. Philip Bourjeard,**  
Sole Inventor and Patentee of the  
**SPIRAL**  
**COMPRESSIONAL BANDAGE,**  
**AIR-PADS for HERNIA,**  
&c.,

Continues to supply his Inventions at  
No. 49, DAVIES-STREET, BERKELEY-SQUARE,  
and No. 11, RUE DES BEAUX ARTS, PARIS.  
(At home from 12 till 6.)

**Apothecaries' Hall of Ireland, 40 Mary-**  
street. The following new Medicines and Preparations are manufactured in the Laboratory on the premises, and a supply constantly on hand:—

Chlorate of Quinine, Perchloric Acid. Permanganate of Potash, and the other Disinfectants now in use. Ether for Local Anæsthetic purposes. The various Granular Effervescent Preparations, &c. &c. &c.

TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

**Brown's Cantharidin Blistering Tissue,**  
prepared from pure Cantharidine. An elegant preparation, vesicating in much less time than the Emp. Lyttæ, P.L., easily applied and removed, and will not produce stranguary or troublesome after-sores. It has received the sanction and commendation of many of the most eminent practitioners in the kingdom.—In tin cases, containing ten feet, 6s. 6d.; and small cases of five square feet, 3s. 6d. each.

BROWN'S TISSUE DRESSING.

An elegant, economical, and cleanly substitute for all ointments as a dressing for Blisters, Burns, &c., and may be called a companion to the above.—In tin cases, containing twelve square feet, 1s. 6d. each.

Sole Inventor and Manufacturer, T. B. BROWN, Birmingham. Sold by all Wholesale and Retail Druggists and Medicine Agents throughout the British Empire.

Dublin Messrs. BOILEAU and BOYD, 91, 92, & 93, Bride-street.

TO THE MEDICAL PROFESSION.

**George Oldham and Co., Pharmaceutical**

Chemists and Apothecaries, take this opportunity to return their grateful acknowledgments to the Profession for the support they have hitherto received, and which they will regard as a fresh motive for exertion. Abstaining, either themselves or their ASSISTANTS, altogether from VISITING or PRESCRIBING, except for the application of Leeches, Cupping, or such operations as are performed under MEDICAL ADVICE, they will continue to devote themselves exclusively to the duties of the pure Pharmacist.

Having had much experience in Practical Pharmacy, sparing neither trouble nor expense to have every article of superior quality, and exercising scrupulous care and attention in the preparation of the various Medical and Chemical Simples and Compounds, the Faculty may place perfect reliance upon the purity of the ingredients employed, and realize from their administration and use the anticipated effects.

Medicines delivered by Vans in all parts of the City and Suburbs, and along the line of the Kingstown and Bray Railway, and in the vicinity of all the Stations, at any hour, free of charge.

Surgical Instruments and Appliances; Home and Foreign Mineral Waters; also every Drug, Chemical, and Pharmaceutical Preparation in use.

MEDICAL HALLS,  
107, GRAFTON-STREET, 64, DAME-STREET, AND  
1, RATHMINES-TERRACE, RATHMINES.

BEWLEY, HAMILTON & Co.'s

**COD-LIVER OIL of 1866.**

**This Oil, as originally prepared by them**  
in 1850, and since then yearly, with the increasing approbation of the profession, and of those numerous Invalids who have derived such inestimable benefits from its use, is extracted from the fresh Livers of the Channel Cods, on B. and H.'s own Premises, and under their immediate superintendence, and is possessed of the properties of this valuable Medicine in an eminent degree.

Sold in Pints, Half-Pints, and Quarter Pints, in Bottles, secured by their Stamps, by

BEWLEY, HAMILTON and CO.,

(Late Bewley and Evans),

STATE APOTHECARIES,

3 AND 4, LOWER SACKVILLE-STREET, DUBLIN.

**J. J. Graham and Co. beg to acknow-**  
ledge with most grateful feelings the liberal and increasing patronage bestowed upon them by the Medical Profession, and to assure them that it is their constant aim to render themselves deserving of a continuance of the same.

J. J. Graham and Co. confine themselves strictly within the limits of the Pharmaceutical Profession, and under no circumstances do they take upon themselves Medical or Surgical duties, other than those performed by the Apothecary under Medical directions—namely, Cupping, Leeching, Blistering, &c.

As the value of a Prescription is completely dependent upon the therapeutic efficacy of the medicines ordered, J. J. G. and Co. are most particular in keeping up a stock of the purest Chemicals and freshest Pharmacopœia preparations. Every article used in the making up of Prescriptions procured from the first Houses regardless of cost, and such as are at all liable to adulteration tested before use; the Profession may therefore rest satisfied that the medicines prescribed will be of the best quality, and carefully compounded under the immediate superintendence of the Principal (J. J. Graham), who resides on the Premises and devotes his whole time and attention to the management, supervising the operations of the assistants, and who is accessible at all hours.

THE MEDICAL HALL, 30, WESTMORELAND-STREET.

ESTABLISHED A.D., 1821.

## THE ADDRESS IN MEDICINE.

DELIVERED AT THE ANNUAL MEETING OF THE BRITISH  
MEDICAL ASSOCIATION,*Held at Chester,*

ON FRIDAY, AUGUST 10TH, 1866.

By JOHN HUGHES BENNETT, M.D., F.R.S.E.,

PROFESSOR OF THE INSTITUTES OF MEDICINE, AND SENIOR PROFESSOR  
OF CLINICAL MEDICINE IN THE UNIVERSITY OF EDINBURGH.AFTER some preliminary remarks, Dr. Bennett proceeded  
thus:—

## PRESENT STATE OF THE SCIENCE OF MEDICINE.

1. It must be admitted that the Descriptive Anatomy of the human body is perfect—a fact in itself of the highest importance in the consideration of medicine as a science. It is in determining its ultimate structure, by means of magnifying instruments, that the greatest progress has been made in recent times; and it is now determined that vital phenomena are essentially dependent on the minutest particles of which every tissue consists. The organs and textures, in fact, are but aggregations of fine molecules, an acquaintance with the properties of each of which can alone lead us to a knowledge of the whole. All attempts to restrict vital action to a cell, to a nucleus, or to any particular element of structure, appears by me to be opposed by an overwhelming series of facts; the truth being, that growth, contractility, and spontaneous movement are as capable of being demonstrated in a molecular vibrio one twenty-thousandth of an inch in diameter, as in the largest cell or muscular fibre. Neither is vital action confined to a so-called molecular or germinal mass, but may exist in perfectly hyaline intercellular substance, as in cartilage, where those changes primarily occur that transform it into bone. It follows that those views whereby, according to some, organic matter is always evolved from within, while, according to others, it is always superimposed from without, are too exclusive, Nature sometimes acting in one way and sometimes in another—here within, and there external to cells.

So far, then, as our present magnifying instruments will allow us to judge, the ultimate structure of a living body is composed of molecules. These possess independent physical and vital properties, which enable them to unite and arrange themselves so as to produce higher forms. In this way nuclei, cells, fibres, tubes, and membranes are produced, the union of which in their turn constitutes the various tissues and organs of the body. Not infrequently the breaking down of one substance is the necessary step to the production of another; so that, either directly or in solution, the histolytic or disintegrative molecules of one period may become the histogenetic or formative molecules of another. This theory of organization not only reconciles the conflicting views of those who still found their notions of development upon the powers of a cell, of a nucleus, or of intercellular substance, but seems to me consistent with all the known facts yet discovered in the organic world.

As an illustration of this process, we can trace with tolerable accuracy the structural history of food as it passes into, through, and out of the body. Thus, an organic mass—say a piece of bread or a beef-steak—first undergoes the histolytic process of disintegration, partly by the mechanical action of the teeth, stomach, and intestines, and partly by the solvent action of the salivary,

gastric, and other juices, until it is reduced by a molecular pulp called chyme. From this pulp a fluid is prepared, which, passing through the villi, enters the chyle-ducts, and in the lymph-glands and thoracic duct, by a histogenetic or formative action produces the blood-corpuscles. These become coloured in the lungs, circulate for a time, and in their turn undergo histolytic solution, and thereby serve to elaborate the liquor sanguinis. This viscous fluid, drawn out through the capillaries, supplies the various tissues, molecule by molecule, with the histogenetic or constant formative material which keeps up their substance. Such substance having served its purpose, is constantly undergoing a histolytic or disintegrative process—is again reduced to a finely molecular fluid, and once more joins the liquor sanguinis of the blood. From this it is finally removed through various channels by the process of secretion and excretion, which in their turn only present still further evidence of this law of molecular organization. Thus the bread or beef-steak, having entered the frame, may be shown structurally to have undergone successive histogenetic and histolytic changes; enjoyed, as it were, life for a time, and ultimately been discarded as inert or dead matter. Compositions and decompositions, however, are not only structural but chemical, and to these we must next pay attention.

2. The great impulse communicated to Animal Chemistry in recent times dates from the labours of those who, by careful analysis, have followed the chemical transformations which plants and animals undergo during their development, growth, and decay. These have shown the relations which exist between the atmosphere, the soil, and the plant—what the latter takes from the two former, and what it gives to the animal who feeds upon it. In the same manner that plants can only grow in those soils which contain the substances necessary to form their tissues, so animals can only be nourished upon those compounds which contain the chemical elements they themselves require. All this being ascertained, what next interests us is the relation which exists between the supply of food and waste of the tissues during their exercise.

Viewed chemically, food may be regarded as a mixture of albumen, fat, and mineral matter, all of which pervade the economy, although the first is most abundant in the fibrous tissues, the second in the adipose and gland tissues, and the third in the bones and teeth. These substances, prepared by the molecular disintegrative process formerly alluded to, are but little changed chemically before passing into the tissues. But in leaving them in order to be excreted, remarkable chemical combinations and decompositions occur, whereby they produce different compounds, such as carbonic acid, water, urea, numerous organic salts, and so on. The nature of these chemical actions within the body is not yet fully understood; so that, although we know the composition of the ingesta and egesta, how the one is transformed into the other by the animal is not so clear.

The view put forth by Liebig—namely, that food should be regarded as nitrogenous and non-nitrogenous—the former being sanguineous or flesh-forming, and the latter respiratory or heat-giving—has long appeared to me erroneous on histological grounds. Every tissue requires both principles. Even chemists themselves have shown by experiment that the idea of the tissues being oxidised during action, and yielding a proportionate degree of refuse like a steam-engine, is not correct. Recently, Messrs. Fick and Wislicenus of Zurich went to the summit of the Faulhorn, one of the Swiss alpine peaks, an ascent which occupied eight hours. During this period, as well as for eighteen hours previously, and for six hours subsequently, they only ate hydro-carbonaceous food, yet a chemical analysis of all the renal secretion passed showed that during and shortly after the ascent the urea excreted was only slightly increased. These facts are irreconcilable with the prevailing chemical theory; for, had muscular exertion increased the oxidation of albuminous material, urea should have been largely augmented, but it was not

so; muscular energy in this experiment having been carried on, without fatigue, at the expense of the carbonaceous substance of the tissue.

Indeed, numerous observations now being prosecuted prove that much has to be accomplished before the chemistry of food becomes the physiology of food, and before the slice of bread or beef-steak can be traced in its progress through the body with the same exactitude chemically as it has been structurally. Even when this is accomplished, we shall have much to learn which chemistry cannot teach us; for, as has been pithily observed, although in the laboratory a pound of flesh is enormously superior in nutritive power to a pound of cabbage, yet, to a rabbit the cabbage is the superior food, whilst to a dog the cabbage is no food at all (Lewis, p. 115). It follows that, though chemistry can teach us much, nutrition, like all other vital processes, can only be rightly studied by the physiologist.

3. The researches of naturalists, it is now admitted, have thrown much light on the Laws of Germination and Reproduction, and have demonstrated to us the nature of several obscure diseases. The observations of Bassi as to the cause of death in certain epidemics affecting the silkworm led to the discovery of the vegetable parasites causing favus, pityriasis, mentagra, and other diseases of man; while the observations of Sars, Von Siebold, Steenstrup, and others, have determined the laws which govern the production of animal parasites. These in turn are related to several interesting facts and generalisations, all of which have tended to augment our knowledge of the animal economy. Need I allude to the doctrine of alternate generation by Steenstrup, of parthenogenesis by Owen, of the origin of tapeworm by Von Siebold, of the economy of the hive by Dzierzon, of pisciculture by Coste, of the formation of the coral reefs and islands of Florida by Agassiz, and the origin of species by Darwin—all of them noble examples of physiological generalisation, several of which have already found important practical applications, while not a few have been of direct service to medicine.

4. A study of Natural Philosophy has led in recent times, perhaps more than that of any other branch of science, to an elucidation of the functions of living beings. What are physical and what are vital actions has long been a subject of discussion. The attraction which the sun exerts upon the earth, that which the earth has upon the magnetic needle, and that which one chemical substance has for another, though differing entirely in their nature, are called physical; but the attraction which the intercellular substance of cartilage exerts upon the lime-salts dissolved in the blood, or that by which any other tissue selects and draws from the liquor sanguinis what enters into its substance, is called vital. Again, the conduction of electricity along a nerve is physical; the conduction of nervous influence along a nerve is vital. We know nothing of the nature of any of these actions, which constitute ultimate facts in science; but, inasmuch as they are not identical we call those which occur in living beings vital. Some of these are altogether peculiar, such as growth in particular directions, muscular contractility, nervous excitability, and mental acts. We observe, however, in a living being, that these properties are more or less dependent upon, mixed up with, and give direction to physical properties. It is the determination of what is due to the one class of phenomena and what to the other, as well as their mutual relations, that has for some time engaged the attention of what is called the physical school of physiology.

And here it must be confessed that, just in proportion as the physical have been made to encroach upon what were supposed to be vital actions, our knowledge has advanced. It has now been proved that much of what was mysterious must be considered due to gravity, imbibition, endosmosis, or chemical, electrical, and mechanical operations. Now, as the laws regulating these physical forces are better known to us than such as govern the vital ones, not only in this way can we comprehend them better, but, when required to modify them by art, we are enabled to do so

with more effect. We cannot, therefore, too strenuously urge forward all that physical research can do for us, although still conscious that, while in this way we may learn much, physics, no more than chemistry, will ever wholly clear up the mysteries which surround the great fact of life.

It is curious, however, to observe that while chemistry has succeeded in manufacturing in the laboratory many of the excretory products of the body, such as urea, taurine, allantoin, formic, oxalic, lactic, butyric, and other organic acids; so the histologist, by the mechanical union of oil, albumen, and mineral matter, has succeeded in forming artificial molecules, nuclei, cells, membranes, and concretions, very similar to what we find in the animal. True, in both cases we must take the proximate principles, which can only be formed by nature; but these given, we learn much of the structural mode of formation and of the chemical decompositions occurring in the animal from what physical experiment has taught us.

Of the numerous ingenious instruments now invented, which have enabled us to determine with rigorous exactitude the time, area, and intensity of phenomena in the living body, whether applied to the velocity of the circulation, force of the pulse, production of electrical currents, rapidity of the nerve-force altered, curves of the crystalline lens, and many other most important facts, I have no time to speak. I have requested my assistant, Dr. Rutherford, to bring with him to this meeting the very ingenious myographion of Du Bois Reymond, with which he will show, what may prove interesting to many present, how the rapidity of the nerve-current can be accurately determined. The inspection of such an instrument, an idea of its construction, and the witnessing one of the experiments which have given such reputation to the name of Helmholtz, will do more than any feeble description of mine to convince you of the great talents and ingenuity of those who now prosecute our science in this direction.

5. Experiments upon the lower animals, I need scarcely say, have added largely to our knowledge of the vital functions. On the propriety of this kind of research I agree with what was stated by Dr. Sharpey in the able address which he read to this Association in 1862—viz., that "when we consider the countless myriads of the brute creation that are daily slaughtered for man's sustenance, or are left to perish from hunger or the severity of season, or fall a prey to their natural enemies, to say nothing of the multitudes killed for sport, surely it is not too much to claim that an infinitesimal share of this vast sacrifice be applied towards the extension of human knowledge and the alleviation of human suffering." It is unnecessary, however, to dwell upon the brilliant results which have been derived from this method of investigation. I would only point out, that a reluctance to engage in it when necessary has vitiated the most important conclusions, of which we have an excellent example in the ideas formed by Sir Charles Bell as to the functions of the anterior and posterior columns of the spinal cord. Having cut the anterior and posterior roots of the spinal nerves in a living animal, and shown that thereby voluntary motion and sensation connected with the parts which received nerves from them were paralyzed, he supposed that the columns of the cord were continuations of these roots, and that section of them would also destroy motion and sensation. But when Brown-Séquard cut across the posterior columns in a living animal, which he did with a knife made for the purpose, it was found that, so far from sensation being prevented, pressure on the leg of the animal gave rise to increased pain. The cause of this is now thoroughly understood from the admirable histological researches of Mr. Lockhart Clarke, who has demonstrated, among numerous important facts for which science is his debtor, that the nerve-tubes of the spinal roots, instead of turning up towards the brain, as had been generally supposed, pass directly inwards to the grey matter, and are there so distributed that no single section of those columns can destroy their power of conducting influences to the brain.

Indeed, experimental and histological research have been so well combined in recent times as to throw a flood of light over the functions of the nervous system. In proof of this, I need only refer to the labours of Bernard as to the influence of the vaso-motor nerves over animal heat.

6. Lastly, the pathologists, who seek to discover, from an inspection of diseased organs after death, the relations existing between morbid conditions and the symptoms or phenomena they occasion during life, have also added largely to the science of medicine. In the same manner that the healthy body has been explored to obtain a knowledge of its structure, so has the diseased body been scrutinised to ascertain the changes produced. As the descriptive anatomy of man is perfect, so is his morbid anatomy; and pathological is as far advanced as physiological histology. Indeed, they may be said to constitute one science. If the organic chemistry of the healthy processes is imperfect, the pathological chemistry of the body is still more so, the latter necessarily being dependent on the former. Such, however, is the activity with which morbid phenomena have been investigated during the last quarter of a century, that in no department of the science, probably, has greater progress been effected.

The meanings of the old terms, inflammation, tubercle, cancer, and so on, are still discussed; but the morbid processes themselves are now well known. These consist of congestion of the blood vessels, and, as a result of this, serous effusion, exudation of the liquor sanguinis, or extravasation of blood. Each of these products undergoes subsequent changes, whereby they are again absorbed into the circulation, either directly, as in the case of serous effusion; or through cell growth, as in the case of exudation; or by disintegration, as in the case of internal hæmorrhages. Not infrequently morbid growths occur, which may originate from irritation of the existing textures, which they more or less resemble; or they may spring up in exudations giving rise to tubercle, pus, and cancer. The tissues also atrophy or degenerate, and in this last case may undergo the fatty, albuminous, pigimentary, or mineral transformations. Concretions of various kinds are deposited in cavities, and obstruct ducts, giving rise to formidable lesions. There may be animal and vegetable parasites. Lastly, the blood itself may undergo alterations from an excess or diminution of its structural or chemical constituents, or it may be contaminated by noxious poisons derived from without, or generated within the body.

A knowledge of these morbid states has now made great progress; and our general ideas of their nature have, in consequence, undergone a remarkable change. It has been shown that the same general laws which regulate growth and other vital functions in health, also influence them, when so disordered, as to constitute disease. The same theory of organization which has changed our views of physiological processes, has had a similar influence on pathological ones. It is not so much the peccant humour or the vascular action of our forefathers to which we attribute structural effects, as it is to the altered chemical, electrical, or vital condition of the ultimate molecules of the tissues themselves. This being the organic cause of disease, our efforts are no longer engaged in the mere study of symptoms, and the grouping them together in accordance with artificial nosologies, but in endeavouring to determine with accuracy the character of the lesion itself, and the precise texture and organ which is involved.

Only a limited idea, however, can be formed of the position of scientific medicine from viewing what has been accomplished by these six methods of investigation separately. It is their union, the assistance that one gives to the other, and the necessity which exists for knowing them all, that require attention in founding a proper basis for medical education. So long as it was supposed that diseases were groups of external symptoms, and that the removal or alleviation of these was the great object to be attained, the rules of art flowing from past experience were easily acquired. But now that every practitioner is

expected to ascertain the nature and seat of the morbid change, not only must these be previously understood, but he must be capable of using all those means whereby they can be detected. A knowledge, therefore, of certain sciences, and of the laws which regulate their course, and their relations with one another, has now become imperative as an introduction to practice.

This mutual relation of the sciences has led to generalisations of the highest importance to our knowledge of vital action both in health and disease. Thus, it having been shown by Grove that the various physical forces—such as heat, light, electricity, gravity, and chemical action—are all correlative, it soon became apparent not only that there was a similar relation between the vital forces, such as those governing growth, nutrition, contractility, and excitability, but also between these and the physical forces. It has further been shown that, just as matter is indestructible, only changing its condition, so is there a conservation of force which only alters its form. In the same manner that heat, light, electricity, gravity, and chemical action are capable of being perpetuated in an incessant round one to the other, so we must regard growth, contractility, sensibility, and even the exercise of the mind, as only varieties in form of that chemical force generated in nutrition, as this in its turn is only an altered manifestation of some other force.

It is by studies in this direction, and in this spirit, that we shall do most to advance the science of medicine, in proof of which I would for a moment refer to the assistance which the sciences referred to have given to one another in advancing our knowledge of disease, and its detection in the living body. How anatomy and physiology aid pathology, and how this in its turn confirms and extends physiology—of this we have an excellent example in the discovery of leucocythæmia, which has proved to us that the views of Hewson, which were so long neglected and held to be doubtful, as to the functions of the spleen and lymphatic glands, are correct, and that they do, as he maintained, form the corpuscles of the blood. Again, many alterations of texture, which morbid anatomy has made us acquainted with, would only have been suspected, but for the help which physical science has furnished in various ways; more especially by chemical tests and analyses, and numerous ingenious instruments. Need I refer to what we now accomplish by means of percussion and auscultation, and to the use of the microscope, speculum, laryngoscope, ophthalmoscope, sphygmograph, thermometer, &c.?

The present stand-point of scientific medicine, therefore, may, I think, be summed up as follows:

1. That the descriptive anatomy of the human body is perfect, and has been thoroughly worked out.
2. That the structural and general anatomy of the human body is very nearly so.
3. That physiology, though greatly advanced, has yet much to teach us as to the functions of the human body, and is at this moment apparently waiting (1) for the organic chemists who are investigating the transformations which food undergoes in passing through the economy; and (2) for the physicists who with newly invented and delicate instruments are investigating the vital functions with a care and exactitude only recently arrived at.
4. That pathology has demonstrated to us the structural alterations produced by morbid states; but is still very deficient in a knowledge of the chemical alterations these occasion. It must necessarily be dependent, however, on the progress of physiology, so that the laws which regulate many diseased processes have yet to be ascertained.
5. That the diagnosis of diseases owing to our combined knowledge of physiological and morbid states, and the cultivation of physical exploration in conjunction with observations of symptoms, is rapidly becoming more exact, and losing its conjectural character. What John Hunter effected for surgery by placing it on a scientific basis is now the object of the well informed physician with regard to the practice of medicine.

## PRESENT STATE OF THE ART OF MEDICINE.

I now turn to the practical side of medicine, by which it to be understood an available knowledge of all those means which contribute, directly or indirectly, to the cure of disease, prolongation of life, or alleviation of suffering.

The long discussions that formerly occurred as to whether the practitioner should be guided by dogmatism or empiricism—theory or observation—deduction or induction—have lost their interest. There are more observers than reasoners, although it may be questioned whether a really perfect observation is not more rare than a sound theoretical conclusion. It is now recognized that science must prevail in the schools, practice at the bedside; and that the more we acquire of both, so much the clearer it is seen how good observation corrects and perfects theory, and how science improves and extends observation. Both have added largely to our resources. Thus it will be admitted that the doctrines of the circulation of the blood, of the independent functions of nerves, the reflex function of the spinal cord, cell-growth, and so on, have been directly serviceable in practice. It by no means follows, however, that great physiological discoveries are often immediately available in this way. The practical value of the discovery of Harvey was not recognized for several years after its publication; and the recently established doctrines of the functions of the pancreas and of the lymphatic glands, and of the glycogenic functions of the liver, have not taught us as yet how better to regulate digestion; influence the formation of the blood, or cure diabetes. But that every physiological truth adds largely to our conceptions of the correct treatment of maladies, is a proposition I must not occupy your time with attempting to demonstrate.

On the other hand, many of those remedies which have been proved to be directly curative of disease—such as quinine, sulphur-ointment, lemon-juice, cod-liver oil, and so on—are entirely the result of empirical observation. With regard to these it is our constant aim to determine the *rational* of their influence. Up to this moment, notwithstanding, there is an uncertainty about the action of numerous powerful drugs in daily use, which is a constant reproach to us, and which we should make a strong effort to remove. It cannot be correctly said, in face of the researches and additions constantly made to our knowledge, that we have been altogether supine on this subject. But it is unquestionable that no vigorous attempt is being made, nor does any organization, so far as I can perceive, hold out a prospect that any is likely to be made, of advancing our knowledge in this direction. In the excellent paper read at the annual meeting of the Association by Dr. Handfield Jones, in 1862, the conflicting opinions which prevailed with regard to the action of some of our most valuable drugs, more especially of digitalis, opium, and quinine, were pointed out. The settlement of these differences is certainly within the reach of scientific investigation, and all that is required are capable workers to solve the difficulties they present. Numerous other agents, however, might be mentioned, the power of which is great, though as yet we know little of their effects. Among these is electricity, the operation of which upon the nerves and muscles has recently been studied by the physical school to a great extent, without, as yet, furnishing us with any exact principles for its application. Duchenne and Remak, it is true, have made many valuable observations, but their views are much opposed to each other. The first considers that an interrupted current should be applied directly to the muscles, while the latter believes that a powerful continuous current sent along the nerves is most beneficial. This and many similar questions require to be solved by investigation.

There are few, however, I fear, who have clearly placed before themselves the great difficulty, labour, and sacrifice of time which therapeutical inquiries necessitate. Indeed, it may be questioned whether any one man, however talented, is capable of such investigation. The wisest among us is apt to be biased by accidental circum-

stances. A case, or series of cases, which have done well under a particular management; the unexpected recovery of an apparently hopeless disease following the administration of a particular medicine; or the fascination which lingers about some plausible theory, may all tend to mislead. The influence of one mind should be corrected by that of another; and the best knowledge in all the departments of the science and art of medicine should be concentrated on the solution of the question proposed. A committee, therefore, would be requisite, which should combine the skill of the anatomical operator, the analytical power of the chemist, and the varied knowledge, theoretical and practical, of the histologist, physiologist, physicist, pathologist, therapist, as well as of the physician whose knowledge of diagnosis is unimpeachable. It would be also advisable to temper the energy and sanguine character of youth with the caution and reasoning power of age. A physiological laboratory, with every necessary instrument, appliance, and chemical, together with an hospital, would be necessary adjuncts.

But when such a committee have completed their labours, published their report, and made their suggestions, even with the assistance of one or more hospital physicians, the coöperation of a large number of practitioners becomes necessary to give it that general and varied trial which is necessary to test its value. No one practitioner, even with the assistance of a large hospital, can hope to examine and carefully record such a number of cases of any one disease as will render his trials of great value. Such, at the same time, is the want of union among medical practitioners, and so difficult is it to impress them with the advantage of working in concert to advance medicine, that several years may elapse before any investigation is finally completed and receives the authoritative sanction of numbers.

And here I would observe, that there is only one way in which, as it seems to me, any particular treatment can ever become, for the future, really authoritative and entitled to the confidence of the profession at large. It is that the facts connected with it should be carefully observed, and the results so recorded that they may be easily compared with similar results obtained by other methods. For this purpose, the age, sex, general vigour of the body, and other facts necessary to be known, under the circumstances, should accompany any general statement as to the good effects of the remedy or treatment, so that all may judge of its value for themselves. This would be the crowning proof of its utility, for it need scarcely be pointed out that even the general adoption of a remedy and a particular practice, or an universal belief in its efficacy, is no guarantee that it is really the best that can be followed. Of this, the practice of bleeding and an antiphlogistic treatment for acute inflammations, and that of a six weeks' course of mercury for the removal of syphilis, both of which prevailed between thirty and forty years ago, offer illustrations.

It is a fact which cannot be disputed, that the mortality of a strictly antiphlogistic practice in acute pneumonia was one death in three cases, and that simply by leaving off a lowering treatment the mortality was diminished to one in seven. In the same manner it has been satisfactorily proved that a general non-mercurial treatment of syphilis cures the disease on an average in two-thirds of the time, and with only one half of the number of secondary cases. Whether there are any cases of pneumonia that still demand bloodletting, or some cases of syphilis that still require mercury, is a question not yet decided, but there can be no doubt that we owe to statistical research the important results to which I have referred. Tabulated facts and numbers, therefore, which correctly estimate the amount of benefit obtained, are what is necessary, instead of vague generalisations, mere opinion, and too often unfounded assumptions. To this end coöperation among members of the profession is necessary, but the difficulty of attaining it may be estimated by the result of a trial in this direction which was commenced by the Association in 1862.

At the annual meeting of that year in London, a committee was appointed, who recommended that various subjects should be proposed for investigation by this Association. Certain members of that committee each agreed to prepare a schedule, to be circulated with the *Journal*, to receive the returns and reports on or publish the results. Accordingly, four such schedules were so circulated, and you may feel curious to know the results of this appeal to upwards of 2000 medical practitioners.

Eighteen schedules were returned to Dr. Fleming, of Birmingham, containing 100 cases in which tape-worm was treated by the male shield fern.

Twenty-one schedules have been returned to myself, containing 152 cases of acute pneumonia, mostly treated on the restorative plan.

Nine schedules were returned to Dr. Harley, containing 23 cases of jaundice, treated by benzoic acid, mercurials and podophyllin.

Three schedules were returned to Dr. Handfield Jones, containing 3 cases of non-syphilitic psoriasis treated in various ways.

The only report published is that by Dr. Fleming, who informs us, that the cases returned to him "establish beyond doubt the great efficacy of the oil of the male shield fern in tape-worm, and its superiority to the other known remedies of this disease. Further," he says, "our report points very decidedly to the most efficient mode of exhibiting the drug; and the whole inquiry has, as I have reason to know, rendered excellent service to therapeutics by making the virtues of the oil of male fern more widely known and employed throughout the profession."—*British Medical Journal*, January 15, 1864, p. 26.

It will therefore be seen that this report of Dr. Fleming has been of great advantage, and so far fully justifies the proposal of the Association. One hundred cases also, where the problem is so simple as the expulsion of a worm, may perhaps be regarded as data amply sufficient to establish the therapeutic virtue of the remedy. Where, however, the problem to be solved is more complex, as in the three other cases, it must be admitted that the returns are by no means sufficient, and that this effort to obtain extensive data for determining the best treatment of acute pneumonia, jaundice, and psoriasis, has as yet been unsuccessful.

Notwithstanding, I still entertain the hope, that through this great Association of medical men something may be done to settle doubtful modes of treatment. If instead of 21 schedules, for example, as to the treatment of pneumonia, yielding 152 cases, it were possible to get 200 schedules with 1500 cases, I think all the vexed questions concerning the treatment of that disease might be permanently solved. Even this only supposes that one-twelfth of our number should fill up a schedule with such cases of the disease as they may encounter for twelve months.

For any scientific investigation, funds must be raised to remunerate the talent and toil which an extended and useful inquiry will necessarily involve. With such aid, properly applied, we have good evidence that much may be done. The recent Government Report on the Cattle Plague, for instance, points out how the co-operation of various individuals may be so directed as to exhaust a medical inquiry. The annual Sanitary Reports of Mr. Simon, conducted on a similar plan, exhibit a series of investigations which are invaluable to the medical man. A like series of reports on diseases, or as to the actions of remedies on the healthy or certain morbid states of the economy, there can be no question, would not only greatly tend to the advancement of medicine, but would gradually exert an authority which would be generally respected. When, also, we regard the advanced condition in which we find the science of medicine, there can now be little fear that such inquiries would conduce to the exclusive systems of treatment, into which some men were formerly led.

It was in every way worthy of the position held by Professor Acland of Oxford that he should have proposed

to the Medical Council that a sum of £250, to test the properties of drugs, be granted out of the contributions levied from the profession. But notwithstanding it constitutes one of the duties of that Council to publish from time to time a Pharmacopœia, the application was refused on the ground that it constituted no part of its business to make such investigations. Exactly the same thing may be said by the government, by the corporations, by scientific societies, and indeed by each medical practitioner. In this way, we arrive at the familiar paradox, "That what is everyone's business is nobody's business."

From all the consideration that I can give this subject, the present stand-point of practical medicine appears to be,

1. That the empirical method of treating disease has reached its utmost limits, and that little further improvement is to be anticipated from it.

2. That the great advance which has taken place in the science of medicine has led, and is leading, to various modifications in the rules of medical practice, which only lately were in general use.

3. That these modifications principally consist in putting more confidence in the powers of nature, having recourse more frequently to the assistance of diet and other hygienic influences, and in employing more sparingly blood-letting and other so-called heroic remedies.

4. That the value of many remedies in certain diseases is unquestionable, and that their judicious employment confers invaluable benefits upon mankind; but the utility of others is disputed or little known, and with regard to these a careful investigation is imperatively required.

5. That such investigations demand great labour advanced knowledge, and much valuable time, and that experience has demonstrated the impossibility of carrying them out satisfactorily without funds to remunerate the investigators.

6. That all applications of scientific treatment require the co-operation of medical men at large, and that no trustworthy results are likely to meet with general confidence in future, unless founded on extensive data, and formularised by a correct statistic.

The learned professor concluded by giving some valuable observations to the effect, that future progress in the Art and Science of Medicine, can only be secured by combined labour.

## Hospital Reports.

### LONDON HOSPITAL.

#### GUNSHOT FRACTURE OF THE TEMPORAL AND FRONTAL BONES.

(Under the care of Mr. LITTLE.)

THE following cases of gunshot wounds occurring in civil practice are sufficiently interesting to deserve record. In both a foreign body was lodged deeply in the substance of the brain without producing symptoms. In both a portion of bone was driven in by the shot, which did not itself enter. The case of the boy has been partially published in the hospital reports, but the post-mortem is so important that we here give the case in full:—

The patient, a boy, aged 13, was shot at by another boy close to him at the time. The gun was loaded with swanshot, the whole charge in a body making a large lacerated wound on the left side of the face. The integuments over a circular area, of which a line from the outer angle of the left eye to left external auditory meatus is a diameter, were completely carried away, together with zygoma and parts of the temporal and masseter muscles. A portion of the outer wall of the orbit was shot away, and there was a depressed fracture in the temporal bone above and rather in front of the auditory meatus.

Here a portion of bone one inch by half an inch in size was depressed at its upper border  $\frac{3}{16}$ ths of an inch;

its lower border was still adherent to the adjacent bone. The boy when admitted on the evening of September 7th, was in a state of extreme collapse; pulse 65, feeble, and intermitting; skin cold, could hardly be roused to consciousness; his eyes were contused and bloodshot; both pupils acted; there was some blood in the anterior chamber of the left.

Suffering so severely from shock nothing was attempted. Brandy was given freely by the mouth and by the rectum, and the next morning he had rallied considerably. He could recognize friends, put out tongue, &c.; pulse 75, weak. Mr. Little made an incision upwards two inches long, commencing in the wound and down to the bone, so as to be able to get at the depressed bone, which was deeply situated. A portion of the over-hanging sound bone was removed with a small trephine, and the depressed portions elevated. The bone in this situation was, of course, exceedingly thin. The dura mater was uninjured. Ice was applied to the wound.

September 9th: Better; pulse 80; takes fluid food freely, as he cannot open his mouth or masticate from the nature of the injury.

10th: Pulse 100, very irregular; skin hot; general erysipelas of face. Warm fomentations instead of ice ordered.

11th: Pulse 98, fuller; skin perspiring; there is free offensive discharge from the wound; the swelling of the face is less; patient rational and hungry.

12th: Better; surface of dura mater covered with healthy granulations; eight ounces of wine ordered. He went on well until the 19th, when his appetite failed; the wound looked unhealthy, and he had a severe rigor, followed by others. He died on the 22nd of pyæmia. No head symptoms. At the post-mortem examination pyæmic deposits were found in the lungs.

In the frontal bone, half an inch above the centre of the left orbit, was a small hole one-sixth of an inch in diameter, leading into a canal through the cerebral membranes one inch and a half into the substance of the anterior lobe of the brain. At the bottom of the canal was a small fragment of bone. There were no signs of inflammation in the neighbouring brain substance or membranes. No shot was discovered; one had, doubtless, struck the frontal bone, driving the fragment in, and had fallen out again. The aperture in the skin would only admit an ordinary probe, it presented to all appearance merely a black point, like others around it, from grains of gunpowder, and it had escaped observation during life.

**FRACTURE OF THE SKULL FROM PISTOL-SHOT.**

[From Notes by Mr. WM. E. DICHEIT.]

R. R., aged 40, described as a writer for the press, but having no regular employment, was brought to the hospital at 3.30 p.m. on Sunday, August 6th, with the statement that he had attempted suicide by firing a pistol at his head. On examination there was found to be a small ragged wound, sufficient to admit a large probe, in the right temporal region, about two inches behind the external angular process of the frontal bone. The integuments were not burned, and there were no signs of powder. The house-surgeon probed the wound in the hope that the ball had glanced off without penetrating the skull, and buried itself under the scalp or in the temporal muscle. The patient, who was quite sensible, pulse good, but frequent, said "that three surgeons had seen him, that the ball had been extracted, and that he had seen it handed round for inspection." The men who brought him in expressed a contrary opinion. The patient having been placed in bed, Mr. Little was sent for, but delayed any operation until some more accurate information could be obtained. At five p.m. the surgeon who had first seen the patient arrived, and said that no attempt had been made to extract the ball, but only to arrest the hæmorrhage, which was considerable. Mr. Little proceeded to enlarge the wound by a T-shaped incision, and discovered

a small triangular piece of bone attached by its base as by a hinge, but with its apex depressed, the base of the fragment being placed anteriorly. It seemed as though the ball had struck the skull obliquely, and depressing this fragment passed backwards into the cerebral substance. Round the apex several small splinters of bone seemed to have been carried away. The fragment was a good deal discoloured by lead. The piece of bone was removed without much difficulty, and a very small flat piece of lead was discovered. There was a laceration of dura mater and considerable bleeding from it. The patient was perfectly conscious throughout the operation.

Monday morning (five a.m.): Patient quite sensible; complained of intense darting pain through his head ever since the operation; had been restless and sleepless all through the night.

Twelve o'clock, Monday: Patient delirious, was with difficulty kept in bed. He remained thus until ten o'clock p.m., when coma supervened, and he died at six a.m. on Tuesday.

Notes of post-mortem examination performed nine hours after death.—The body was well nourished.

In right temporal region was a T-shaped incision communicating with the bone. In the bone was an irregular fracture sufficient to admit the point of little finger. There was also an aperture in the dura mater at the seat of fracture, but not to the same extent. On surface of dura mater were two or three small fragments of bone, and a flat piece of lead very small. The cavity of arachnoid contained coagulated blood, thin, opaque, almost purulent fluid. There was a track leading almost down into the corpus striatum, but not quite entering the ventricle. At the bottom of this was a fragment of bone, about the size of a pea. In the Pineal gland was a small, fine, waxy deposit, having a villous-looking exterior. Mr. Little could not find any considerable fragments of the ball. The weapon used was a small revolver, carrying an elongated projectile scarcely the diameter of a pea, propelled by detonating powder.

**THE CHOLERA WARDS OF THE HOSPITALS OF LONDON.**

**THE LONDON HOSPITAL.**

SINCE our last statement there has been a considerable diminution in the number of cases admitted to this hospital, and although a special cholera hospital has been opened in the neighbourhood, which would partially account for this decrease, we may fairly conclude that it is to some extent due to the gradual subsidence of the epidemic. On Friday last there were 96 cases in the cholera wards. The day before there had only been 5 admissions, 2 of which were cases of cholera, the other 3 being diarrhœa. This brings the total admissions since the outbreak up to 612, of which 268 have been fatal, as will be seen from the following figures:—

|          | Admissions. | Recoveries. | Deaths. | Remain. |
|----------|-------------|-------------|---------|---------|
| Cholera  | 464         | 141         | 255     | 68      |
| Diarrhœa | 148         | 107         | 13      | 28      |

An attentive examination of the facts also leads to the conclusion that the diminution in the number has been gradual. This point is best illustrated by a daily return for last week which we here add:—

*Admissions into the Cholera Wards of the London Hospital.*

| Aug.   | CHOLERA. |          | DIARRHŒA. |          |
|--------|----------|----------|-----------|----------|
|        | Males.   | Females. | Males.    | Females. |
| 17th   | 8        | 3        | 2         | 4        |
| 18th   | 3        | 2        | 1         | 2        |
| 19th   | 3        | 1        | 0         | 1        |
| 20th   | 3        | 1        | 3         | 2        |
| 21st   | 4        | 2        | 1         | 0        |
| 22nd   | 1        | 0        | 2         | 4        |
| 23rd   | 2        | 0        | 2         | 1        |
| Totals | 24       | 9        | 11        | 14       |

As to age, 7 boys and 1 girl affected with cholera were under 10 years old, 3 boys and 4 girls between 10 and 20. Only 4 cases of cholera were between 20 and 30, 7 between 30 and 40, 2 between 40 and 50; above that age 5.

As to treatment, Dr. Davies continues the calomel. Dr. Fraser has tried chlorate of potash and hydrocyanic acid, and Dr. Clarke has prescribed tr. ferri sesquichlor. and quinine. During the week another case has been tried by injection of salines into the veins. At first it seemed quite a hopeful case, but we regret to hear that the patient has since died. We had hoped to find a much greater success by venous injections at this hospital, as during the last epidemic the results were more favourable. Dr. Little, we believe, had 3 successful cases in 1849. 5 others died; but of these 4 were moribund. Perhaps the want of success this year may be due to the treatment being only adopted in the worst cases.

#### ST. BARTHOLOMEW'S HOSPITAL.

Out of 6 cases admitted in as many days, only 1 was dead at our last inquiry. One of the cases was that of a nurse occupied in the hospital. Calomel and opium at first, with warm bath and warm foot-bottles, as well as sinapisms to the epigastrium, have been the chief remedies employed at the suggestion of Mr. Smee. Peroxyd of hydrogen has been given in four cases, but without marked effects. Beef-tea, with Condy's fluid and brandy, have been administered in the form of enemata. Sometimes a few minims of laudanum are added to allay cramp, but not where any drowsiness is present.

#### THE GERMAN HOSPITAL.

This institution, situated at Dalston, admitted 23 cases between July 19 and August 23; but they did not come from the immediate neighbourhood—indeed, no less than 19 were from the eastern districts. Out of these cases 8 are reported as now recovered, and 14 remained under treatment. Some of the cases were of a mild type. Small doses of calomel, castor-oil, and camphor, have each been tried. Subcutaneous injections of turpentine and camphor were prescribed in 2 cases. Result—abscesses at the part injected. In this hospital the cholera eruption has been observed, and we hear that the temperature is being regularly noted.

#### BELLEISLE HOSPITAL SHIP.

The cases we mentioned last week, as under the expectant method, have, as yet, exhibited a smaller mortality than any other sets of cases on board. Yet, the numbers being only small and consequently presenting differences, a too hasty judgment could not be pronounced. Ten new cases have been admitted during the week. It is noteworthy that, at present, no case has been satisfactorily traced to importation from abroad.

NEWCASTLE COLLEGE OF MEDICINE.—At the annual meeting of Members, held on the 1st inst., the following gentlemen were appointed the council of management for the ensuing year:—President: Rev. Canon Whitley. Registrar: M. Denis Embleton. Treasurer: Dr. Thomas Humble. Secretary: Dr. G. H. Philipson. Other members of Council: Dr. Edward Charlton, Dr. C. J. Gibb, Dr. Charles Gibson, and Dr. William Murray.

#### ADELAIDE HOSPITAL.

### FLAP EXTRACTION OF CATARACT; SPONTANEOUS EVOLUTION OF THE LENS; EXCELLENT RECOVERY.

(Under the care of Mr. B. WILLS RICHARDSON.)

[Reported by Mr. ALEXANDER DUKE.]

MRS. C., æt. 55, was admitted into the Adelaide Hospital, Dublin, April 18, 1866. Both eyes were cataractous, the cataracts in each being mature, amber-coloured, and stellate. The centres of the cataracts were of a darker amber than the circumferential portions. The pupils were regular, and the irides acted briskly. The patient could distinguish the hand with either eye, when it was passed between the eye and the light.

Although one might think from the semi-transparent look of the marginal portions of the cataracts that more light should get into the eyes than the patient's amount of vision indicated, yet when Mr. Richardson examined the eyes with Liebrich's ophthalmoscope, the pupils having been previously dilated with atropine, not a glimpse could be obtained of either choroid or retina.

After some preliminary constitutional treatment and the subsidence of the sharp north-easterly wind, then particularly severe, Mr. Richardson proceeded to extract the cataract from the right eye, by the ordinary upper flap operation. Dr. Walsh took care of the lower eyelid while Mr. Richardson himself with the left hand managed the upper one, and at the same time commanded the eyeball by the ordinary manœuvre.

When puncturation of the cornea was effected, and while the knife was traversing the anterior chamber, a very small portion of the iris got over the edge of the knife which Mr. Richardson succeeded in disengaging, with the exception of an almost imperceptible shave. Counter-puncturation was next accomplished and the flap completed.

The eyelid having been carefully let down, Mr. Richardson, after the expiration of a few moments, again raised it, for the purpose of introducing the cystotome to open the capsule. The margins of the corneal wound were seen to be in perfect apposition. Just, however, as he was about to pass the cystotome behind the flap, to divide the capsule, spontaneous evolution of the cataract commenced. It was gradually and slowly extruded until it had almost half passed through the corneal wound. It then stopped, Mr. Richardson immediately passed a lens-hook into it and removed the cataract without the slightest difficulty. No vitreous humour escaped, with the exception of a very small and firm piece, not more than an eighth of an inch in its longest diameter. The upper lid was again let down, and in a few moments raised to see how matters looked. The pupil was in its natural position and the margins of the corneal wound apparently in exact coaptation.

The lids of both eyes were then closed and kept together by single pieces of court plaister. Linen blinkers were secured to the head, the patient was placed in one of the ends of the long ward which was moderately darkened. Everything, it may be said, proceeded favourably after the operation. Some pain, notwithstanding, was felt in the eyeball on the fourth day; but, as it was unaccompanied by swelling of the lid, increased febrile, or fever, Mr. Richardson considered it neuralgic, and ordered the patient wine, a fuller diet, quinine mixture, and a few alterative doses of blue pill, with some quinine also, in each pill. The lids were firmly glued together by a semi-transparent secretion, a most favourable circumstance. They were neither red nor swollen, and there was no appearance of pus. Indeed, Mr. Richardson observed, that although he used strips of

court plaister in this case, it was evident that they were unnecessary, and he doubted if he would again use plaister strips after extraction. As Mr. Dixon remarks, the lids are sufficiently secured by the drying of adhesive secretion from the Meibomian follicles and conjunctiva, so that the plaister is scarcely necessary. Moreover, it is liable to become exceedingly rigid, angular, and thereby extremely irritating to the patient.

The eye was examined on the sixth day after the operation, Mr. Richardson observing to the class that the greatest manipulative delicacy must be observed in the process of separating the lids. When bathing the adherent palpebral fissure the surgeon must take particular care not to press the upper lid, as the corneal flap being situated beneath it, the wound might be seriously disarranged, recent adhesion may be ruptured and vitreous humour ejected. If this escape occurs to any extent vision might be altogether lost. The lids having been carefully unglued and separated, the whole corneal wound was found to be united. The cornea was convex, shining, and transparent. The pupil was central and nearly circular. The anterior chamber was somewhat deeper than before the operation, from the absence of the lens. The conjunctiva was slightly injected and very slightly thickened externally. The patient could see Mr. Richardson distinctly, and describe his dress, &c.; but no further trial of sight was made on that occasion, and the lids were again closed. Mr. Richardson remarked that he coincided with Mr. Dixon that possibly it is better not to test the sight immediately after extraction of the lens as disappointment might at the moment result, which may interfere with recovery. In this case the patient, immediately after the lens was removed, although not questioned regarding her vision, volunteered the statement, that the light was blue, and was all she could see. And nevertheless on the sixth day after the operation her vision promised to be excellent.

7th day: Complained of occasional shooting pains in the eyeball. They were unaccompanied by fever, or by increased injection of sclerotic or conjunctiva. Mr. Richardson, however, thought it judicious to order her twice daily blue pill, with the addition of sulphate of quinine.

8th day: Chemosis had disappeared and the sclerotic injection had gradually faded. The pains complained of on the day before were not so frequent. Could differentiate the fingers held some distance from the bed.

9th: Eyeball was assuming its natural colour. Pains had ceased. To get up and open eye freely.

Haus. rhei cras mane sumend.

It is unnecessary to recapitulate the daily reports of the case up to the period she left for the country, as nothing untoward subsequently occurred to retard the recovery of the eyeball from the operation. She was discharged on the 8th of June, and then could distinguish small objects on the wall at the end of the long ward, and could read large type at about two feet from the eyes. Mr. Richardson saw her within the last few days. She was able to walk out by herself.

With regard to the spontaneous evolution of the lens which occurred in this case, Mr. Richardson directed the attention of the pupils to the fact, that neither he nor Dr. Walsh were touching the eyeball at all when it was taking place. Mr. Richardson mentioned that the controlling of the eyeball by the fingers should be carefully avoided after counter-puncturation has been effected and until the surgeon is about to press out the lens. If spontaneous evolution takes place without discharge of vitreous humour, it is a fortunate circumstance; for, as Professor Gräfe observes, in spite of all the instrumental auxiliaries so ingeniously devised for the removal of the lens, spontaneous evolution of the latter, as it takes place through a gaping section, either by ocular pressure alone or by gentle assistance from without, is doubtless the relatively best mode of evacuation, because the least injurious to the eye. To the fact that it favours this consum-

mation, the method of flap extraction is manifestly indebted for the purity of its results.

It is no matter what care or precaution the surgeon may take to prevent the escape of aqueous humour and the resulting turning of the iris over the edge of the knife, it will occur notwithstanding. It has been truly observed that this is one of the most troublesome accidents which can happen during the operation. In this case, however, Mr. Richardson succeeded in almost completely disengaging the iris and finishing the section of the cornea.

When the iris has fallen forward over the edge of the knife the mode of acting differs according to the size of the puncturation wound of the cornea. If it is small, some surgeons would postpone the operation to a future day; whereas others, Desmarres, for instance, close the lids, wait a few minutes to see if the iris resumes its normal position in consequence of the resecretion of the aqueous humour, and then finish the section. But, should the anterior chamber have been half traversed by the knife when the accident occurs, surgeons appear to be agreed that the practice to follow is to endeavour, as was done in this case, to disengage the iris, and if successful, then to complete the section by counter-puncturation, &c. Suppose, however, the iris cannot be disengaged from the edge of the knife different procedures are then recommended to be followed. Thus, the extraction knife may be withdrawn and the section completed with either the secondary or narrow-bladed knife, or with Daviel's scissors, taking care not to wound the iris. Again, the incision may be finished with the double-bladed knife. On the other hand it is advised that in case you cannot disengage the iris, excise a portion of it and then finish the corneal section. The only inconvenience in the latter case being a misshapen pupil.

It is found in practice that iritis is not more frequent after this abscission than otherwise. Indeed, in the operation of scoop extraction, excision of a portion of the iris is had recourse to, partly under the supposition that such removal has a tendency to avert or diminish the liability to inflammation of the iris. At one time Mr. Richardson thought of extracting in this case by the scoop method, but when he considered that there was a good anterior chamber, a brisk iris, neither a prominent nor a sunken eye, a quiet patient, having full control over herself, he gave the preference to ordinary flap extraction.

STRANGULATED OBLIQUE INGUINAL HERNIA: *no symptom of intestinal obstruction previous to the hernia becoming irreducible*: HICCUGH, STERCORACEOUS VOMITING AND CONSTIPATION FOUR DAYS BEFORE ADMISSION INTO HOSPITAL: ABSENCE OF PAIN AND TENDERNESS FROM THE COMMENCEMENT OF THE OBSTRUCTION: PERSISTENCE OF THE SYMPTOMS AFTER REDUCTION OF THE HERNIA BY THE TAXIS: DEATH: POST-MORTEM: INTERESTING SURGICAL QUESTIONS INVOLVED IN THE CASE.

(Under the care of Mr. B. WILLS RICHARDSON.)

[Reported by Mr. G. R. TRIPHOOK.]

Stephen Mc—, æt. 52, by trade a tailor, was admitted into the Adelaide Hospital, Dublin, under the care of Mr. Richardson, at about one o'clock p.m., on Friday the 6th July, 1866.

He was then suffering from hiccough, vomiting of a brownish stercoraceous-looking fluid and constipation, and had a tumour in the right inguinal region, having all the characters of an oblique inguinal hernia. The testis was situated at the lower part of the tumour. The latter was oval, tense, but not tender.

The history of the patient's hernia, as far as it was possible to discover, was as follows:—

Eight years ago while lifting a heavy "goose" or iron to press his work, he felt something give way, when a tumour immediately appeared in the right groin. He forthwith

applied at the Richmond Hospital, and was there told that he was ruptured and was given a truss. Although he wore the truss very irregularly he suffered no inconvenience from the complaint until within the last few days, and never had any symptoms indicative of intestinal obstruction until the hernia became irreducible. His symptoms on admission into the Adelaide Hospital were as follows:—

There was a hard, tense tumour in the right inguinal and scrotal regions, having the characters of an oblique inguinal hernia. There was neither pain nor tenderness since in the abdomen or tumour then, or indeed at any time the hernia became irreducible on the previous Monday, when the symptoms of intestinal obstruction first began. He vomited at intervals a brownish coloured fluid. Hiccough accompanied by windy eructations were most constant. The pulse was 112 and weak; he could scarcely walk. Mr. Richardson was immediately summoned. In the meantime the resident pupils had him placed in a warm bath, tried the taxis, but did not succeed in reducing the rupture. He was not apparently weakened by the bath. They gave him some wine, however, immediately after it. A purgative enema with *asafoetida* was administered with the long tube. The injection came away untinged by *fæces*.

Mr. Richardson arrived about two o'clock p.m., and had the patient placed under the influence of chloroform, when, after some minutes, the tumour was reduced by steady, persevering, but gentle, manipulation. After the reduction, the finger could be passed through the external ring into the inguinal canal. Nothing could be felt in the canal or in the iliac region to lead to the supposition that the hernia was not perfectly reduced.

When the anæsthetic influence of the chloroform had perfectly subsided, the abdomen was again carefully examined, but he distinctly stated that there was no tenderness in any part of it. It should be remembered that he had neither pain nor tenderness since the symptoms of intestinal obstruction set in, or it might be thought that this absence of pain was the concomitant of that deceptive truce so frequently seen immediately before death in many diseases, particularly in cases of strangulated hernia.

After the hernia was reduced, the patient expressed himself much relieved, the hiccough ceased, and his collapsed appearance was not so striking.

A pad was placed over the inguinal canal, and was secured by a figure-of-eight bandage. He was ordered to dissolve some pieces of ice in his mouth during the day, and to have a grain of opium at once. He was given wine regularly, a turpentine and *asafoetida* injection was administered. This likewise came away apparently without *fæces*. In a couple of hours after the hernia was returned the hiccough recommenced, but not then so frequently; vomiting also recurred, and of a similar stercoraceous brownish-looking fluid, which some of the gentlemen present thought had a decided feculent odour. The pulse fell to 84, and he had neither pain nor tenderness. The bowels still remained constipated; therefore, it was thought that another turpentine and *asafoetida* injection might be given him with the long tube. It also was discharged without *fæces*. He continued free from pain, and although he had occasional hiccough, he slept part of the night.

The next morning (Saturday), the hernia again descended, but was reduced without any difficulty; pulse 96, and weaker; countenance somewhat of a sunken leaden hue; no tenderness of abdomen, neither was it enlarged by tympany; no uneasiness in the inguinal region; hiccough as frequent as ever, and he vomited occasionally the brownish feculent-looking fluid; the bowels continued constipated. He was ordered another *asafoetida* and turpentine enema, and to have, every second hour, one of the following pills:—

R Sub. hydrarg. gr. xxiv.

Ext. opii, gr. vi. Misce.

Ft. massa in pil. xii. dividend.

Mr. Richardson ordered the calomel, under the supposition that the persistence of the symptoms of intestinal obstruction

might probably have been caused by latent inflammation of the portion of bowel that had been protruded, and that thereby it was rendered incapable of taking on its peristaltic function. No tenderness, however, could be discovered in any part of the abdomen. It was endeavoured to support his strength with wine, brandy, and essence of beef. The ice was continued. The hernia was prevented from descending by digital pressure, which duty some of the students undertook. He was seen again at three o'clock p.m. Nothing feculent was brought away by the enema given in the morning. The hiccough continued to be very frequent, and he vomited at intervals the same kind of brown fluid. Had taken two of the pills, and was somewhat drowsy. He was given another enema similar to the last, and this time it was decidedly feculent. The digital pressure was changed for a pad and figure-of-eight bandage over the seat of the rupture.

Nine o'clock p.m.: Pulse had fallen to 86, but it was exceedingly weak; vomiting and hiccough had almost ceased, but the pulse being so weak, it was thought advisable to give him whisky instead of brandy or wine; no tenderness in any part of abdomen, and it continued free from tympanitic enlargement. An enema now caused a large feculent evacuation. The patient continued in this state till about four o'clock a.m., when he became so weak, with a failing pulse, that the resident pupil gave him the whisky every half hour; the weakness notwithstanding increased, and he died at seven o'clock a.m. It may be here observed that while the patient was under observation he passed a full amount of urine.

The post-mortem examination was made at noon by Messrs. Duke and Triphook, Mr. Richardson superintending.

The abdomen having been opened, it was found to be free from effusion, either of serum or of lymph, excepting at one particular part of intestine. What was supposed to have been the hernial portion of intestine was perfectly and completely reduced, and was a part of the ilium, about eight or nine inches from its connexion with the cæcum. This portion of the gut, for about four inches in the direction of jejunum, was slightly hardened and thickened. It was intensely injected with blood, as well as a triangular portion of the mesentery connected with it, the apex of the angle being about two inches from the gut. The contracted gut had nothing of the chocolate tint so frequently seen in strangulated intestine, and it was perfectly free from ecchymosis. There was some lymph in patches on the peritoneal investment of this hardened piece of gut, and the peritoneum separated from the latter with facility. With the exception of where the lymph was attached, the peritoneum did not appear to be duller than natural, neither was there any other sign of gangrene in the contracted part. It lay partly in the true and partly in the false pelvis. The gut below the contracted part was somewhat diminished in calibre, but the intestines above it were greatly distended by flatus, and here and there presented patches of injected vessels. The peritoneum was polished and shining in all parts, except where the lymph was deposited at the seat of constriction, and slightly over the back of the bladder.

The hernial sac was partly in the inguinal canal, and partly also below the external abdominal ring.

The stomach and other abdominal organs were healthy.

Mr. Richardson considered this case of much interest, and he thought it scarcely necessary to say that it caused him much anxiety. The persistence of the symptoms of abdominal obstruction after the return of the gut at first gave rise to the suspicion that possibly the bowel and sac during the taxis had been forced between the abdominal muscles and peritonæum—the *reduction en bloc* of the French, or that the persistence of the symptoms were caused by stricture of the neck of the sac.

Against the first supposition, however, there was the fact that the hernia descended on two or three occasions since

it had been reduced on the day of his admission, which it would scarcely have done if it was a complete *reduction en bloc*. It is an exceedingly rare thing to occur in this kind of reduction. Mr. Richardson remarked that in the experiments by Cloquet regarding *reduction en masse* or *bloc* on the *dead* subject, the tumour went in and out with equal readiness when the ring was loose and wide, but that in the living subject it was so rare a circumstance that hardly a case of the kind had been discovered by him in the journals which he had the opportunity of searching. No doubt Sir Charles Bell described an exceptional case somewhat of the character of *reduction en masse*. That case ended fatally, although the intestine could be returned. The stricture was formed by the neck of the sac, which, together with the neighbouring portion of the abdominal peritoneum, was detached from the aponeurotic ring and the contiguous part of the abdominal parietes, so as to allow the intestine, although closely confined by the stricture, to descend into the scrotum and pass back again freely. This case, however, was a congenital one.

*Reduction en bloc*, it appears, may take place under two very different conditions, which it is of vast consequence should be remembered—namely, with or without tumour. In the case, for instance, recorded by Scarpa, there was not externally the smallest appearance of tumour in the inguinal region. Sabatier, on the other hand, has described a case in the *Médecine Opératoire*, in which he was enabled to feel a roundish tumour at considerable depth. It is almost superfluous to observe that it is in cases without tumour, that the question as to the propriety of an exploratory operation must be one of great anxiety to the surgeon. Of course when there is tumour after the supposed reduction of a hernia, the symptoms of strangulation still persisting, there can be little hesitation regarding the conduct to pursue. Mr. Luke lays some stress on the point, while endeavouring to establish diagnostics of *reduction en bloc*, whether the margins of the ring are unobstructed or obscured. In the last condition he considers the presumption to be that the sac has not been reduced. The case of Stephen Mc— affords but little support to the value of this diagnostic, for the ring was remarkably clear, and yet the sac was found passing through it after death. Mr. Richardson thought a good deal would depend on the thickness of the sac, as to whether or not the ring would be obscured by it. A thin sac would scarcely obscure the ring to any extent.

Owing to the persistence of symptoms of strangulation in Stephen McC.'s case, the question arose as to whether or not an exploratory operation would have been justifiable. Mr. Richardson resolved, however, not to operate, for he thought that if it was *reduction en bloc* without tumour, the hernia would not have re-descended with such facility. He observed to Mr. Archdall, who saw the case in hospital, that he considered the persistence of the symptoms to be caused by the hernial portion of bowel being rendered incapable of recovery and resuming its peristaltic action in consequence of the injury it had sustained from its incarceration before the patient's admission into hospital.

The post-mortem examination supported this view, the incarcerated gut having been altered in the manner described, death being the result of that alteration, and of enteric inflammation in different parts of the small intestine between it and the stomach. Mr. Richardson considered the case also worthy of record from the fact of the absence of pain and tenderness with such inflammatory mischief going on in the abdomen. He observed that, suppose after the re-descent of the bowel, an operation had been performed, its appearance would not have been found of a nature to warrant its being retained in the inguinal region. When the abdomen was first opened, he thought the case was one of latent enteritis independent of the rupture; but when the hardened and injected portion of gut was discovered, and with it the inflamed triangular piece of mesentery attached to it, the intestines above this part being much distended, and those below it contracted, and when he recollected that

before the hernia became strangulated the patient never had the slightest symptom to lead to the inference that previous organic contraction of the gut had taken place, he thought it a fair and reasonable assumption that the point of departure of the disease which led to the death of McC. was the prolonged incarceration of the portion of ilium above described.

In conclusion, Mr. Richardson stated that it might be recollected that the patient while under observation passed a full quantity of urine. His case, therefore, did not afford any support to the view of Dr. Barlow, who considers the amount of urine excreted as a sign of the seat of obstruction. According to this gentleman, when the obstruction is "high in the canal," as in the jejunum or ilium, absorption is partially checked, and a small quantity only of urine is consequently excreted. If, on the other hand, the occlusion is in the rectum or sigmoid flexure, the whole of the capillaries of the alimentary canal are free to absorb fluid, and thus the blood contains more watery elements, and there is an abundance of urine. This, as Dr. Habershon states, is a very uncertain sign. What little dependence should be placed on it was clearly seen in McC.'s case, for there should, according to Dr. Barlow's view, have been a scanty excretion of urine, the obstruction being in the ilium, and notwithstanding the fluid was passed in abundance. Indeed, when it is recollected how excellent is the absorbing power of the stomach, and how great a proportion of the ingested fluids is taken up by the vessels of this organ, we can easily account for the full quantity of Stephen McC.'s urine, and can hardly think that much dependence can be placed upon the quantity of urine passed in cases of intestinal obstruction as a diagnostic of the seat of occlusion.

## RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

### DR. LYONS'S CLINIQUE.

#### DIARRHŒA: CHOLERA.

*Congestive Diarrhœa*.—This is, perhaps, the only form of malady which may be regarded as a special lesion of the intestine, producing flux of the bowels, and not dependent on a pre-existent or concomitant affection in other organs.

Its symptoms are not either constant or characteristic and it is rarely a fatal affection. It is probably, in the opinion of Dr. Lyons, due to a state of congestion of the intestinal mucous membrane, affecting different portions of the alimentary canal in different cases, and varying much in extent, degree, and duration. It cannot be too often impressed on the mind that in the view of "Diarrhœa" in its several forms now under consideration, all forms of diseased action whatever, and they are various, are excluded from consideration, though presenting intestinal flux as a clinical phenomenon, however well marked, which are referrible to well known and generally recognized independent pathological conditions; all those cases, in fact, and they are not few, in which diarrhœa is to be considered by the pathologist and physician as a sub-dominant clinical feature, and not as constituting an essential disease *per se*. Such are the forms of diarrhœa incidental to fevers, enteric ulceration, tuberculosis, &c.

Amongst the conditions recognized by Dr. Lyons as the result of extensive anatomico-pathological investigations at home and abroad, and considered by him as capable in various degrees of producing intestinal flux from various parts of the alimentary tract, may be noted—

1. (a) A condition of the stomach, in which the mucous membrane exhibited increased vascularity, with marked prominence of the gastric glands.
- (b) An opposite state of the organs, in which its coats were bloodless and had a parchment-like aspect, with atrophy of the glands.
2. A marked increase of vascularity, often amounting to great congestion in the gastro-splenic omentum.

3. A state of more or less intense congestion of the small intestines, sometimes extending throughout their whole tract, and manifested on both the serous and the mucous surfaces. In some instances this congestion has been so remarkable on the peritoneal aspect as to give the whole jejunum and ilium a deep bluish red tinge. The excess of blood determined to the abdominal organs, under these circumstances, is extreme, and readily explains the occurrence of copious flux as an effort to relieve congestion.

4. Associated with the last-named condition there will usually likewise be found extensive congestion of the mesentery and mesenteric glands. The conditions here specified indicate a marked stagnation in the portal system; that relief of this state of vascular repletion should be very readily effected by an increased drain from the mucous surfaces, in many instances, is highly probable.

5. A state in which patches of vascularity were to be observed at various parts on the mucous aspect of the jejunum and ilium. These vascular patches, when closely examined, were found generally to be in connexion with the minute glandular apparatus of the intestine; (a) arranged in arborescent vascular rings surrounding independent solitary bodies; (b) surrounding the patches of Peyer; (c) oblong patches, including groups of solitary and agminated glands; (d) peculiar states of limited vascularity affecting the free borders of the valvulæ conniventes.

6. A condition of the mucous membrane, in which it was generally thickened, and its epithelial coat very soft and easily detached, constituting the "ramollissement" of authors.

7. An opposite condition, in which the mucous membrane—most generally that of the small intestine—was remarkably diminished in thickness, its coats atrophied, and its glandular apparatus degenerated—the parchment-like condition of the mucous membrane—(Lyons).

Besides the states above-mentioned, numerous pathological conditions are to be met with in the intestines; but they are all referrible to morbid action in other organs or portions of the system as their point of departure. Thus, the follicular lesions of typhoid fever, the enteric ulcerations which attend the last stages of phthisis, the exudation of diphtheritic character occasionally found in the small intestine, the specific forms of congestive action which attend the scorbutic state of the system, all belong to the domain of special pathology, and the association of any amount of intestinal flux is but a secondary, though necessary, consequence, and diarrhœa thus becomes the symptom of disease, and ceases to be the disease itself.

#### CHOLERA: ITS PATHOLOGICAL ANATOMY AND PATHOLOGY.

The most careful examination after death in cholera cases exhibits a few well-marked general conditions, but fails to discover specific localised lesions. The surface of the body retains the more or less bluish coloration present before death. In many instances there is a restoration of warmth after death to parts of the body which had been cold during life. The muscular system is usually observed in a state of persistent general tonic contraction; the hands being often clenched, and the feet slightly turned in, with the heels drawn up. In men of strong frame the muscular masses will often be seen to show in high relief in the arms and forearms, the thighs and calves of the legs; and in not a few instances, from the effects of powerful post-mortem muscular contractions, slight changes of position in the upper or lower extremities, or in the whole body, have been observed, amounting, in extreme cases, to an actual locomotion, falling of the body from a table or other support on which it had been placed, and have led to the erroneous supposition that the patient had not been dead when first abandoned, and that life might have been preserved. Such false impressions have been the basis on which have been founded so many thrilling tales of "the dead alive," premature "burial alive," &c., all equally devoid of truth. When cut across, the muscles, such as

the recti, gastrocnemii, &c., retract with much force, and leave a wide gaping interval between the surfaces of section. This retractile power is observable for many hours after death.

On pursuing the dissection, the tissues are found, in many instances, remarkably dry, this is especially so in those cases in which there has been copious elimination of the fluids by vomiting and purging. The muscles are found dry and red on section, and dark-coloured, thick, tarry blood is found in the cavities of the heart. More or less considerable congestion of the lungs is found in some cases, but not in all. Occasionally congestion of the membranes of the brain is observable; but as the result of a wide experience, Dr. Lyons is of opinion that congested states of the brain and spinal cord or their membranes are but casual and incidental phenomena in the morbid anatomy of cholera, and the same may be observed with regard to the liver, spleen, and kidneys.

While very variable conditions are noticeable in different cases in the mucous membranes of the upper and lower portions of the alimentary tract, that of the jejunum and ilium will be found to exhibit, in a large number of fatal cholera cases, appearances of a very peculiar character. When purging and rice-water evacuations have persisted for some hours before death, the entire surface of the intestines is washed to a degree of cleanness which no artificial process could accomplish. A bright pink or roseate hue characterises the membrane, and it is entirely devoid of the ordinary unpleasant intestinal odour.

The contents may be almost *nil*, in which case the intestinal tube will be found contracted. In other instances the canal is filled with the characteristic rice-water fluid. In marked contrast with the pink hue of the mucous surface is the peculiar white granular appearance of the minute glands of the intestines, both the solitary and agminated glands being raised prominently above the surface, and having somewhat the aspect of a number of whitish sago grains scattered on a pink ground.

The intestinal villi are often seen prominent above the surface, in some instances being somewhat softened and frayed at their free ends, the natural velvet-like aspect of the mucous membrane being thus much increased. The condition just noted may perhaps be further accounted for by the thoroughly clean-washed state of the whole alimentary tract; the naturally viscid intestinal juices being carried away by the abundant watery secretions of the disease. "In fact," says Dr. Lyons, "no artificial preparation short of the destruction of the elementary parts of its mucous surface could give to the whole alimentary tract so thoroughly cleansed an appearance as that which we have often seen produced in a very few hours in some of these rapidly fatal cases of cholera."

It is to be observed that in those cases of cholera fatal after a brief seizure, and where the disease kills without time being allowed for the production of the ordinary phenomena of vomiting and purging, the contents of the intestines are bilious and fœcal, and the above appearances on the mucous surface are absent or imperfectly developed.

In view of the main and essential phenomena of the disease, and having regard to the fact that death may take place in cholera without vomiting or purging, Dr. Lyons regards the morbid state, known as cholera, as one in which a depressing or paralysing agency of great intensity is brought to bear upon certain centres of the nervous system. These centres are neither in the brain nor the spinal cord, for the pathological anatomist fails to find any constant lesion in either the cranium or the spinal canal. There remains for consideration the great secondary system of the vagi and the sympathetic chain which rules over the organs of circulation, respiration, and digestion.

In the suddenness with which the circulation is paralysed, and the radial and other peripheral pulses are obliterated in many cases, may be recognized the effect of this potent agency acting directly on the cardiac and general vaso-motor plexuses. In the dyspnœa, epigastric anxiety,

nausea, and vomiting, will be recognized the deranged action of the plexuses of the vagi going to the lungs and stomach. In the upset of the equilibrium of the abdominal circulation, and the vast outpouring of the white fluid elements of the blood, may be recognized the derangement of dynamic action in the solar plexus, the semilunar ganglia, and the splanchnic supply of nerves generally. In the cramps will be recognized sympathetic irritation of the nerves of spinal origin, connected, on the one hand, with the vertebral ganglia of the great sympathetic, and distributed, on the other, to the muscles of the trunk or extremities.

To seek in concrete form for the matter of the "cholera poison" in the atmosphere we breathe, the water we drink, in the egesta by the mouth or anus of the sick, or in the fluids and tissues of the body of those dead of the disease is, Dr. Lyons holds, a puerile proceeding unworthy of the present advanced state of pathological science, and betrays a total incapacity for the study of so profound and complicated a diseased state.

In the view above adopted all remedies by stimulation, astringent action, application of warmth, &c., can be regarded as but palliative. Hygienic rules and sanitary precautions will maintain that stable equilibrium of health, which best resists morbid influences and so prevents disease; but to cure cholera we have yet to discover a specific power equally potent as that which strikes down so irresistibly the functions of the great nerve centres of the Vagi and Sympathetic.

Many of the positions here laid down are well illustrated by the case of the woman E. I., admitted into Dr. Lyons's wards on the 25th August at ten a.m. She was a married woman, aged about 50, and had been ailing for some days previously, and had some, but neither excessive nor specific, vomiting and purging on the 24th. She was, however, able to be up early on the 25th, and went to prayers; while at her devotions she was seized with faintness. Her stomach and bowels acted once with brownish egesta. When admitted at ten a.m., she was haggard, wildly apprehensive, cramped in the legs, almost pulseless, with the breath and tongue cold. No further vomiting or purging took place. She gradually sank, became livid, exhibited the wrinkled and clenched state of hands and feet, and resisted all attempts by the most active internal and external stimulation to promote reaction. She died quietly at six p.m. This Dr. Lyons regards as an example of dry cholera, fatal by profound nervous depression.

### CHOLERA: ITS EARLY TREATMENT, AND, ESPECIALLY, ITS PREVENTION.

(BY MEANS OF DILUTE SULPHURIC ACID, OTHERWISE THE COMMON VITRIOL OF COMMERCE IN WATER.)

By HENRY MACCORMAC, M.D.,

CONSULTING PHYSICIAN TO THE BELFAST HOSPITAL; PHYSICIAN TO THE CHOLERA HOSPITAL; EX-PROFESSOR OF THE PRACTICE OF MEDICINE IN THE BELFAST MEDICAL SCHOOL; VISITING PHYSICIAN TO THE DISTRICT ASYLUM FOR THE INSANE; AUTHOR OF "CONSUMPTION AS ENGENDERED BY REBREATHEd AIR," "ASPIRATIONS FROM THE INNER LIFE," ETC.

CHOLERA is propagated by infection, but some are much more readily implicated than others. Dirty unwholesome habits, coupled with bad food, foul water, crowding, and intemperance, are the great collateral provocatives. There ought to be no eating and drinking between meals, and no excess. Water, sweet and soft, whatever else be drank, is desirable at meals. When a filter is required, a charcoal filter is best. But any efficient filter is good. Toast-water, weak tea or coffee, cold, without milk or sugar, forms an excellent dinner drink. Toast-water is best prepared by pouring a gallon of boiling water on a square inch or so of bread, well browned. When cold, it is fit for use.

Absolute cleanliness and perfect ventilation are the best disinfectants. The air of rooms, by night especially, should be renewed continually. I had the windows of the cholera hospital, under my charge, taken out and kept out, day and

Impurities should not be suffered to accumulate. They ought to be continually removed and buried in the soil.

Aperient medicines, castor-oil, salts, and the rest, demand the greatest caution. They should not be taken unless directed by a medical man. Aperients, in fact, when improperly exhibited, bring on diarrhoea, and diarrhoea, unless checked, is the too frequent stepping-stone to collapse and death.

A teaspoonful of dilute sulphuric acid, taken in a little water, every half hour, or oftener, will, in the great majority of instances, arrest diarrhoea. It will not only arrest the diarrhoea or looseness which ushers in cholera, but if taken night and morning, as I have fortunately been able to ascertain, has also the infinitely desirable property of averting diarrhoea and cholera altogether.

A tablespoonful night and morning, proportionably less to children, of a mixture containing half an ounce of dilute sulphuric acid in twelve ounces of water, is a convenient mode of giving the dilute acid. Dilute sulphuric acid indeed is found in all apothecaries' shops, but may be prepared at any time by adding ten pounds of water to a pound of strong acid.

This cheap and effective remedy should be universally accessible. For the merest trifle, inasmuch as strong sulphuric acid costs but a penny a pound, any city, however extended, might be protected. Wherever cholera subsists or is anticipated, the dilute acid should be at hand. It ought to be in readiness in all factories, schools, barracks, asylums, hospitals, ships, in fine, in every house. Municipalities, boards of health, and medical men should see to it. Along with reasonable temperance, strict cleanliness, and proper ventilation, cholera might, as thus, be arrested with as much certainty at least as anything in the world is certain, many lives would be preserved, and great suffering averted.

Belfast, 7th August, 1866.

### TREATMENT OF CHOLERA BY CHLOROFORM INHALATION.

By Dr. G. de GORREQUEE GRIFFITH,

PHYSICIAN TO THE HOSPITAL FOR WOMEN AND CHILDREN, PIMLICO; PHYSICIAN-ACCOCHEUR TO ST. SAVIOUR'S MATERNITY, ETC. ETC.

Now that the cholera is upon us, I think it behoves medical men to give their experiences—various though they may be—of the remedies adopted in the treatment of this fearful complaint. Therefore, would I make public in your journal a mode of dealing with this malady, which I first practised when in India, and subsequently on my return home.

The plan to which I refer is, that of putting the patient to sleep by administering chloroform, and of maintaining this sleep for some time if necessary.

The period at which I prefer to begin the inhalation is early in the onset of the affection, or at latest when the depression is becoming severe, and the patient is sinking into the state of collapse; but I should not hesitate to employ the use of this drug even when the stage of collapse was fully established.

In those cases, where there is no graduation of the severity of the symptoms, but the patients are struck down at once owing to the dose of the poison poured into the system, I should administer this remedy without delay, and with the assurance that the sufferer would have immediate relief.

In those instances in which I have adopted this plan of dealing with the disease, if there have been cramp it has been at once allayed; if sickness, it has been in some checked, in others quite arrested; if violent purging, it has been moderated; while the heart, which has been labouring in the endeavour to perform its office, is relieved, and resumes its work with less effort as well as with greater effect, as shown by its sounds becoming louder, its beats becoming stronger, and by the return of the pulse at the wrist, the lividity of the face and hands disappearing, and the red glow of returning circulation taking its place. I would advance a case typical of the foregoing remarks.

ploy, a strong, healthy, active woman, sent for me early in the morning. As I entered the house I was somewhat startled by her shrieks, and on enquiring the cause I was told that it was on account of the great pain from the cramps: when I came into her room I scarcely recognized her face so completely altered was it; her voice also was so changed that I did not know it to be the same as I was accustomed to hear; there was that lividity which takes place in cholera, and which makes the cholera patient such a terrible object, the skin was shrivelled, the hands and feet cold, and the warm breath had itself turned cold.

Nothing would stay on the stomach; soon as anything was taken it returned, and the vomiting was accompanied with the peculiar purging which nothing would check. I put the patient under the influence of chloroform by means of inhalation, and kept her so for a little time; when she awoke the cramps had ceased, the sickness did not return, and the purging was checked, but not altogether stopped. I continued to give chloroform internally in combination with small quantities of tinct. opii; the mixture being suspended in egg, well beaten up, and a little ice-water taken after it.

On the second day after her seizure she was up and able to be about.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 29, 1866.

### MR. BOWMAN'S "ADDRESS IN SURGERY."

THE "Address in Surgery," by Mr. BOWMAN, delivered at the recent meeting of the British Medical Association, and published in our last number, will be read with avidity by all Medical Practitioners in the British Empire. The high position of the Lecturer, his eminent talents as a Physiologist and as a Surgeon, and his well-merited success in the specialty to which he has of late years almost exclusively devoted himself, will all secure for his utterances the most respectful attention. Amidst the rapid succession of events which have characterized the medical history of our own times, it may almost be overlooked by some that Mr. BOWMAN is, if we may so term it, a specialist only by accident, and that the same genius and industry which he has lately brought to bear upon the department of Ophthalmic Surgery, would have rendered him equally distinguished in any department of the healing art, or indeed in any scientific pursuit whatever. To him, if we are not greatly mistaken, is due the chief merit of the now celebrated work on "Physiology," which bears the joint names of TODD and BOWMAN, and we say this without meaning any disparagement to the memory of Dr. TODD, who for several years before his untimely death was so much engrossed with the duties entailed upon him by his private practice that he was unable to follow up those strictly scientific researches which, however, he had had very considerable share in instituting and promoting.

When we state that we have been somewhat disap-

we are expressing a rather heterodox opinion, and one in which, perhaps, we shall have very few followers. But while we fully and cordially admit the high merit of the "Address" as a literary composition, and the exalted philosophical spirit with which it is pervaded, we fail to perceive in it that lofty and independent tone which we might have expected when we consider the position of the Lecturer and his own individual freedom from the thralldom of collegiate ties. It is true that he advocates in general terms the unity of the Profession, and deprecates the contentions which formerly existed between the different Medical Corporations, and sarcastically alludes to the facts that HARVEY, the illustrious discoverer of the circulation of the blood, was elected Professor of *Surgery* at the College of Physicians, and that WILLIAM HUNTER was admitted a Member of that Corporation only after he had formally renounced the practice of Surgery; but when we come to inquire what remedial measures are proposed by Mr. BOWMAN for the still existing anomalies in the Medical and Surgical Colleges, we find that he utters no definite opinions, and shrouds himself under the enunciation of mere generalities.

But as shewing the manner in which private friendships may influence the opinions of even the most exalted philosophers, perhaps no better example can be taken from Mr. BOWMAN'S "Address" than that portion where he eulogizes the memory of four men who have lately departed from this earthly scene, and from whom Mr. BOWMAN thinks that "a comprehensive view of all interests, judicious counsels, and a liberal course of action, might have been expected, had they been spared to us." Now the four men thus introduced are, Sir BENJAMIN BRODIE, JOSEPH HENRY GREEN, ROBERT BENTLEY TODD, and Sir CHARLES HASTINGS. Of the last-named physician, who has so lately disappeared from our ranks, we can only observe that he died at a tolerably ripe old age, and as that his, honourable as it was, was nearly finished, and that very little more could be expected than that his successors should bring into the field as much energy, simplicity of character, and honesty of purpose as he himself displayed on all occasions when the interests of Science or of the Medical Profession were concerned.

But the same remarks which apply to Sir CHARLES HASTINGS, certainly do not apply to either Sir BENJAMIN BRODIE, JOSEPH HENRY GREEN, or ROBERT BENTLEY TODD. The first was no doubt a most distinguished Surgeon and a Physiologist and Philosopher of a very high order, but in what way could we have expected that if his life had been spared (he was upwards of eighty when he died) he would have evinced "a comprehensive view of all interests, and pursued a liberal course of action?" JOSEPH HENRY GREEN was also a most distinguished Surgeon, and a gentleman of high literary attainments, but his life was one continued series of suc-

prehensiveness of views, these qualities must have been exhibited in private rather than in public, for he certainly never exposed them to the gaze of the world. He was a thick and thin supporter of the now defunct principles and practice of the College of Surgeons of England, and had his life been spared (and he was a septuagenarian when he died), he would no doubt have maintained to the last the views which he always advocated. ROBERT BENTLEY TODD stands in a different category, for he was prematurely cut off in the midst of a very lucrative but most laborious practice, and it is now impossible to estimate how far his aims and aspirations were connected with the general interests of the Profession of which he was so distinguished a member.

Mr. BOWMAN, moreover, in his advocacy of unity on the part of the Corporations, actually gives them credit for proceedings, in reference to which we conceive that some of them at least deserve only censure. What can be more inappropriate, for instance, than applauding the College of Surgeons of England for taking under its protection (for a consideration) the class of Surgeon-Dentists? Surely the ordinary diploma of the College is not so very difficult of attainment that it is necessary to lower the qualification in favour of a particular class, and if this principle be once admitted, why does not the College, as it already has a Midwifery Board and a Dental Board, establish other Boards for aurists, oculists, stone-cutters, corn-cutters, dermatologists, or any other specialists who may be expected to bring in money to the College coffers? Verily we believe that the College policy is anything but calculated to bring about the unity of the Profession, and on the contrary it seems to us to be dictated only by sordid pecuniary interests.

We have made the above remarks with considerable pain, as we conceive that the sentiments expressed by Mr. BOWMAN on the points to which we have referred, are not only open to comment from extrinsic criticism, but are inconsistent with the views expressed by Mr. BOWMAN himself in the course of his "Address." In all other respects we have only to repeat the expression of our warm admiration of the eloquence and learning displayed in the "Address," which is worthy of the Lecturer and of the Association before whom it was delivered.

#### CHOLERA AT SOUTHAMPTON—LATEST NEWS.

DEATHS at Southampton, from all causes, in the week ending August 18, 1866, seventeen, being three below the average mortality.

Deaths from cholera since my last report, August 15, seven, making twenty-one to this evening, during the present month.

EDWIN HEARNE.

Southampton, August 24, 1866.

AN amusing printer's error has occurred in the columns of one of the leading Paris evening papers, which has excited no small amount of merriment at the expense of a man of real talent. The following paragraphs, intended to have been printed separately, were by some blunder so arranged that they read consecutively:—"Doctor X. has been appointed head physician to the Hôpital de la Charité. Orders have been issued by the authorities for the immediate extension of the Cemetery of Mont Parnasse. The works are being executed with the utmost despatch."

#### PROGRESS OF THE CHOLERA.

THE remarks made under this head in our last number were strikingly confirmed by the report of the Registrar-General which was issued on the same morning, and to which we now devote a few lines. These weekly returns are, in point of fact, more accurate and complete than the daily ones, and therefore furnish a good starting point, to which the later diurnal figures are easily appended.

In the thirty-third week of the year, ending on Saturday, the 18th instant, 1799 deaths were registered in London, exceeding by 467 the estimated number, which, with a correction for increase of the population, should be 1332. Yet although the total mortality exceeds the average by 467, we find that it is less by 500 than in the previous week. This diminished mortality is evidently due to the decrease of cholera, since the deaths from this disease have fallen to 455 against 781 in the week preceding, and 1053 in the week before that. It is clear, therefore, that the epidemic is gradually subsiding; and although no effort should be relaxed, we are justified in expressing our hopes that London may shortly be relieved from the scourge; at the same time, it must not be forgotten that on former occasions a subsidence has been followed by a renewed outbreak, and it is not without some misgivings that we can look forward to the autumn. While waiting calmly for the event, and working for it, we have time to analyse the lessons of the past five weeks. During that period the mortality of London has been at the rate of 37 per 1000 living annually. But taking only the south and west districts, occupied by a population of 1,400,000, the mortality has been scarcely 1 in the 1000 above the average. In the southern districts alone the mortality by cholera has been 3 in 1000; they are mostly low-lying and poor districts, and in 1849 and 1854 they consumed the impure water of the tidal Thames. At those dates they were decimated by cholera. Their water is now drawn above Teddington Lock; hence, probably their tolerable immunity during the present epidemic. The northern and central districts have fared nearly alike. Those supplied by the new river have escaped much more than those obtaining their water from the Lea. The area occupied by the East London Company has been that where the cholera has chiefly raged. Even in St. Botolph, in the city, where several deaths from cholera have occurred, it appears that this company enters the city at this very point. The company professes to draw its supply from the river more than two miles above Lea Bridge; but at this latter spot there exists a communication with the river which, perhaps, had better be done away with. As to the district lying at a low level, we cannot but remember that the central and southern districts, which have hitherto nearly escaped, lie just as low. Moreover, as to drainage, it will be found that the area occupied by the epidemic is not inferior to the southern districts, since the low level sewer is at present incomplete. The cholera mortality in the east districts contrasts most strongly with the others, being, in fact, at the rate of 39 per 1000 in Bethnal Green; 50 in Mile End; 70 in Poplar and Bow; and 80 in Stepney. London is divided into 37 districts for registration purposes—of these 31 have suffered slightly, and the remaining 6 have been ravaged by the epidemic to such an extent as to swell their mortality from 30 to 40 fold above the other districts; now, all these 6 districts derive their water from the Old Ford reservoirs. The 37 districts are divided into

135 sub-districts. Of these 21 drink the same water, and have suffered six weeks in succession. The remaining 115 have suffered slightly, except in St. Botolph and a few other places, where the same water finds access. Although, then, it may be possible that the present water supply from the Old Ford reservoirs may be no worse than others, as the epidemic would only slowly subside, we agree with the Registrar-General that here is a lesson that "should be taken to heart by every water company and every community in the Kingdom."

That the decrease of the cholera is likely to be continuous, may, perhaps, be augured from the gradual but progressive diminution of the deaths which, from Wednesday, the 15th inst., have been as follows:—

|                                                   | Deaths from Cholera. | Deaths from Diarrhœa. |
|---------------------------------------------------|----------------------|-----------------------|
| August 16, Thursday, . . . . .                    | 64                   | 40                    |
| " 17, Friday, . . . . .                           | 60                   | 25                    |
| " 18, Saturday, . . . . .                         | 51                   | 28                    |
| " 19 and 20, Sunday and Monday together . . . . . | 70                   | 29                    |
| " 21, Tuesday, . . . . .                          | 51                   | 27                    |
| " 22, Wednesday, . . . . .                        | 35                   | 14                    |
| " 23, Thursday, . . . . .                         | 38                   | 17                    |
| " 24, Friday, . . . . .                           | 35                   | 19                    |

In our last report on the progress of the epidemic we drew attention to a certain disposition it has exhibited to spread. Numbers of cases of cholera have been reported in various parts of the country, but we are glad to announce that, except in Liverpool, it cannot be said to be epidemic in any of our large towns. At this important port it continues to spread. The report circulated that it was passing by is not borne out by the official returns, which show the deaths from cholera in the last seven weeks to be successively 4, 19, 45, 87, 101, 126, and 157. Out of the 518 deaths registered in the borough of Liverpool in the week ending 18th, there were 63 from diarrhœa, in addition to the 157 reported above as due to cholera. This was an increase of 31 in the number of deaths from cholera, and a decrease of 12 in those from diarrhœa. At the very commencement of the epidemic, THE MEDICAL PRESS AND CIRCULAR called attention to the unhealthy state of Liverpool, and with cholera on the increase the authorities may, perhaps, be more active in sanitary improvements than would otherwise have been the case. We hear and trust it is true that the board are raising the salary of their active Officer of Health, Dr. Trench. It is in following his suggestions alone they may hope to cope with the sanitary state of their city. It may be worth while to repeat the further fact, that there is in Liverpool a very considerable localization of the disease—by far the larger number of cases having occurred at the north end.

In other parts of the country our report could be but similar to that of last week. A few fresh towns have been named as visited, but the cases are not numerous.

The same observation applies to the Continent, where nothing fresh has occurred, save an increase in the cases in the armies of Prussia and Austria.

### Notes on Current Topics.

THE CITY OF LONDON GUARDIANS.—The working of our local authorities has been exemplified during the week, at the meeting of the guardians of the City of

London Union in a manner deserving of passing notice. Among other business a letter from Mr. Simon was read stating that the Privy Council had been informed that the well which supplied water to the workhouse was not in a proper condition; that sewage from a sink made its way into this well; that there was a most offensive smell from a sink near the well. The Privy Council inquired if these statements were true, adding, politely, that in this case the guardians would, no doubt, be anxious at once to remedy them. How was so momentous a subject treated by the city guardians? It was resolved that *Mr. Simon be written to, asking him for the name of his correspondent.* We commend this instance of local action (or would it be more correct to say inaction?) to all whom it may concern. Nevertheless, it was to be expected that at least one of the members of this board would have possessed sufficient olfactory sense to decide on the presence or absence of a "most offensive smell from a sink near the well." Perhaps these gentlemen have too lofty a notion of etiquette to protect the poor of whom they are the guardians until they are informed of the names of those who are honest enough to notify to them the nuisances it is their duty to remove. At the same meeting a correspondence was read respecting a complaint made by Dr. Letheby that he was unable to make proper returns of the condition of choleraic disease in the city in consequence of want of returns by the officers of unions. Upon this the clerk remarked that they were not required to make these returns to Dr. Letheby, and doing so would involve an immensity of trouble without any advantage accruing, adding that Dr. Letheby could come or send his officer to examine the books if he liked. Thus an enlightened clerk to a Board of Guardians not only contents himself with a disclaimer of any legal obligation to second the efforts of one of the foremost sanitarians of the day, but offers his dictum that no advantage would result from doing so, and condescendingly offers Dr. Letheby the privilege of coming to examine the books for himself, and this in the midst of a fearful epidemic. Surely the force of bumbledom can no farther go.

CONVICTION UNDER THE NEW SANITARY ACT.—The first conviction has already taken place, and augurs well for the future working of the Act, of which we gave a full account in last week's MEDICAL PRESS AND CIRCULAR. Dr. Ballard is the medical officer whose energy has thus been prompt and efficient. By his direction a house was visited—overcrowding was proved—and this being a nuisance under the Act, a summons was taken out, heard in the Clerkenwell police court, and a penalty of 20s. obtained. The fine is small; but for the first case, may be considered satisfactory, besides which, in the event of a second conviction being obtained within a period of three months, the magistrate has power to close the house for such a period as he thinks fit. This may be held *in terrorem* over the heads of all offenders. While the public is fairly alive

to the value of sanitation is the opportunity for energetic men to enforce the new law; and we are glad to hear that notices under the 22nd section have been served on the owners of numerous filthy tenements. We trust they may every one find that at length the strong arm of the law can reach them.

**DEATHS OF MEDICAL MEN FROM CHOLERA.**—Last week we announced the deaths of three Parisian physicians from the epidemic. We have now to add the name of M. Boussard, who died a few days ago from the disease, contracted during the discharge of his duties as resident medical officer at the Hospital of St. Antoine in Paris. Two of his predecessors in the office died during the epidemic of last summer.

Dr. J. Duncan, a pupil of Liston, and in large general practice at Edinburgh, has also just died of cholera at the town of Tours, in France, where he was making his customary annual holiday.

**THE TEMPLE PUMPS.**—The water of the four pumps in the Inner and Middle Temple has been subjected to examination by Dr. Noad. He found the water of the pump in Hare-court to be so contaminated with organic matter, probably of animal origin, as to be unfit for consumption. In consequence of his report, the handle has been removed by the authorities. The water of the other pumps is fit for consumption; but in the present state of London drainage it would be wiser to fill up all the wells. The best must be liable to the imputation of being mere reservoirs of filtered sewage.

### THE BRITISH ASSOCIATION.

THE thirty-sixth meeting of the British Association for the advancement of Science was opened in Nottingham last Wednesday. The Corn Exchange, a building centrally situated and well adapted for the purposes of a reception room, had been fitted in the usual manner, and was thronged from morn till night by fresh arrivals of members and associates. There was a desire amongst the authorities and the inhabitants generally to promote a successful meeting, and, from the appearance of the inauguration, there is a fair prospect of the realisation of the best wishes of the friends of the association. The number of members and associates up to Tuesday night was 1,290, being 700 short of the total at the great meeting at Birmingham last year, and that number is, of course, exclusive of the very considerable augmentation of the lists by later comers. In point of attractiveness there will be no falling off. The names of nearly all the scientific men most closely identified with the British Association are amongst those present, and there are one or two "lions" of the favourite African traveller type, who will give special interest to the meeting. Sir Samuel Baker, now the guest of Mr. Webb, at Newstead, is to read a paper before the geographical section, and also contribute some observations on the ethnology of the regions near the source of the Nile. Of the regular staff of the council there were, Professor Philips, the retiring president; Mr. W. R. Grove, Q.C., M.A., F.R.S., the president-elect; Sir R. Murchison, Professor Playfair, Mr. Fairbairn, Mr.

Hawksley, Sir J. Bowring, Mr. Crawford, Sir John Lubbock, Lord Wrottesley, Colonel Sykes, M.P., Mr. Hynd, Mr. Joseph Heywood, Mr. Le Neve Foster, Admiral Belcher, Sir E. Rawlinson, Mr. Griffith, the general secretary, Mr. F. Galton. The local secretaries are Dr. Robertson, Mr. E. J. Lowe, and the Rev. J. F. McCallan.

Early in the afternoon a meeting of the general committee was held in the Mechanics' Hall, a new and well-constructed building, the use of which is described by its name. It contains a well-stocked library and museum, and a large assembly room, in which the general meeting was held. The principal business was the receiving of the parliamentary and new committees—the former regretting that science is still neglected in the teachings of public schools, and the latter suggesting the propriety of confiding the Meteorological Department of the Board of Trade to the management of some scientific body.

At eight o'clock in the evening there was a large assemblage of members in the theatre to hear the address of Mr. Grove. The proceedings were, as usual, inaugurated by the exchange of courtesies between Professor Phillips, the late president, and his successor, Mr. Grove, who thereupon took the chair. The learned gentleman then delivered the inaugural address. He commenced by speaking of the surprise which our rude ancestors would feel if they could rise and see our country in its present state. The immense progress which had been made between their time and ours had all been effected step by step, and it would be difficult to trace its causes. He looked upon the growth of associations, such as that with which they were connected, as being one great cause of the rapid advance in science. In its annual visits to different localities, the association not only imparted fresh local knowledge to the visitors, but left behind stimulating memories which roused into permanent activity dormant or timid minds. He wished to submit to his audience certain views of what had, within a comparatively recent period, been accomplished by science, what had been the steps leading to the attained results, and what, as far as he might fairly form an opinion, was the general character pervading modern science. He then proceeded to show that the development of observational, experimental, and even deductive knowledge was either attained by steps so extremely small as to form readily a continuous ascent, or when distinct results apparently separate from any co-ordinate phenomena had been attained, that then, by the subsequent progress of science, intermediate links had been discovered uniting the apparently segregated instances with other more familiar phenomena. The president concluded with the following words: "We, this evening assembled, ephemera as we are, have learned by transmitted labour to weigh, as in a balance, other worlds larger and heavier than our own, to know the length of their days and years, to measure their enormous distance from us and from each other, to detect and accurately ascertain the influence they have on the movements of our world and on each other, and to discover the substances of which they are composed. May we not fairly hope that similar methods of research to those which have taught us so much may give our race further information, until problems relating not only to remote worlds, but possibly to organic and sentient beings which may inhabit them—problems which it might now seem wildly visionary to enunciate—may be

solved by progressive improvements in the modes of applying observation and experiment, induction and deduction?"—*Daily Telegraph*.

THE POOR-LAW MEDICAL INSPECTORS IN IRELAND.

THE Medical Officers connected with the administration of the Poor-law Charities of Ireland number nearly 1000; they are, as a rule, highly educated, intelligent gentlemen; their influence for good or ill is very considerable, and it is rare indeed to hear of anything to their discredit. Of necessity their services are of a most arduous nature, and their remuneration small. We refer to the subject now, as we believe an opportunity will shortly arise for the appointment of a Poor-law Medical Inspector. Surely the Commissioners will be able to select for the appointment from the many well qualified candidates, some one who is or has been a Poor-law Medical Officer. This would be promotion in the service, and would be taken as a boon by the entire body.

OWING to press of matter we are obliged to hold over important communications, including "Correspondence."

NOTES ON THE TREATMENT OF 123 CASES OF CHOLERA IN THE LIVERPOOL PARISH INFIRMARY, July and August, 1866.

By J. WILSON McCLOY, M.D., &c.,

RESIDENT MEDICAL OFFICER AT THE LIVERPOOL PARISH INFIRMARY.

THE following brief record of the treatment adopted in 123 cases of cholera which have occurred in, or been brought to, this institution during the present epidemic, may not prove uninteresting to the profession. "It must be confessed that the means employed were sufficiently various in their nature; and the narrative of their effects may be useful, by inducing caution in the employment of those which have been found inefficient and injurious." I can conscientiously say that each particular mode of treatment received a fair and impartial trial. I shall hereafter have occasion to contrast the relative severity of the cases treated by each method.

The first cases (two) were brought to this hospital on the 10th of July. Both were in the evacuation stage, and were treated with astringents, stimulants, and ice-water. The astringent used was a mixt re containing spirits of chloroform, Battley's sedative solution, creasote, and compound chalk mixture. The stimulant was brandy, freely and frequently administered. Ice-water was given *ad libitum*. The symptoms of collapse rapidly set in, and both cases proved fatal: one in twelve, and the other in six, hours after admission.

On the 12th of July the disease unfortunately made its appearance in the founding department of the institution. This was one of those sporadic, or, at least, unaccountable cases which we occasionally meet with. A nurse in one of the founding wards, who had not for months been out or in communication with anyone from without, was suddenly and unaccountably seized with violent vomiting, painless, profuse purging, and violent cramps in the extremities. The case was considered one of cholera. The woman was removed at once, the place thoroughly disinfected, the bedding, &c., burnt, and the children transferred to a separate ward. This woman was treated in a similar way to the former cases, and with the same result, death occurring in twelve hours after admission.

The same night two of the children to whom this woman was nurse, and who slept with her, were seized with choleraic symptoms. They were treated with camphor, according to the "Rubini" plan. Both cases proved fatal: one in six, and the other in eleven, hours.

The following morning four other children, also charges

of this woman, were seized. The camphor treatment was adopted, and three cases proved fatal.

From this time till the 26th of July there were 56 entries. Of these 5 were moribund on admission—dying in from two to seven hours.—We have then a total of 51 cases treated up to the 26th ult. Of these 19, were by camphor, 7 by ice, and 25 by what I shall call the "mixed plan." The following are the results:—

| Cases. | Mode of treatment adopted.  | Deaths. |
|--------|-----------------------------|---------|
| 5      | (Moribund on admission)     | 5       |
| 19     | Camphor ("Rubini" plan)     | 13      |
| 7      | Ice to spine, and ice-water | 7       |
| 25     | Mixed treatment             | 13      |
| 56     |                             | 38      |

Only seven of these fifty-one cases were in the stage of collapse, the rest were in the evacuation stage. In estimating the value of the camphor treatment it is only fair to state that it was principally pursued amongst a most unfavourable class of patients. I allude to those puny, rough-skinned, pot-bellied, emaciated children, so common in the lower ranks of life, and in the founding department of workhouse infirmaries. Ice to the spine, either alone or alternated with hot-water bags, was miserably unsuccessful. The application did not seem to have the slightest effect in producing reaction where there was any considerable collapse. While the ice-bags to the spine were borne without complaining, a similar application of water at 120° Fahr. caused the greatest pain. The mixed treatment included the use of astringents, sedatives, stimulants, ice, ice-water, the hypodermic use of morphia, hydrocyanic acid, strychnine, and camphor, dry heat sinapisms, stupes, &c. The astringent mixture, which was the same as that used in the first cases, speedily arrested the vomiting and purging; but this was not followed by any general improvement. Dry heat and sinapisms proved beneficial. Brandy and ice-water were administered freely.

On the evening of the 26th the castor-oil treatment was first ventured on as a sort of forlorn hope. The following is the history of the first case in which it was used:—

Ellen M——, aged 36, admitted at twenty minutes to seven p.m. Has been ill with diarrhoea for a day and half. Was treated with astringents and stimulants. Previously a healthy woman. When admitted she seemed in a semi-narcotized condition, from which she was with difficulty roused. Features pinched; expression anxious and fearful; feet and legs blue and icy cold; arms cold and fingers corrugated; forehead covered with a clammy perspiration; eyes sunken and surrounded with a livid ring; voice husky; tongue, lips, and breath very cold; pulse absent in radial, and but very feebly perceptible in brachial artery; neither purging, vomiting, nor cramps; small intestines distended. Ordered sinapisms to stomach and abdomen, and hot bottles to feet and legs. To have an ounce of castor-oil and two drachms of tincture of hyoscyamus at once. Small quantities of water at temperature of room. At a quarter to seven the oil was rejected. To be repeated. Ten minutes past seven: Oil retained; to be repeated. A pint of salt and water, at 120° F., to be thrown into the rectum. Half-past eight: Purged freely. To have half an ounce of castor-oil. Twenty minutes past ten p.m.: Oil retained. Seemed more lively; pulse imperceptible in radial.

July 27th: Quarter past twelve a.m.: Purged twice in last hour; evacuated matter horribly offensive and of an ash-brown colour. She is much warmer and more natural in appearance; pulse feebly perceptible. Oil to be repeated.—Ten minutes past three: Much better; vomited once and purged twice in the last two hours; forehead warm; pulse distinct in radial; great thirst. To have water *ad lib.*—Forty minutes past eight: Improving rapidly; pulse moderately good; has been purged once; matter still very offensive; feet and legs warm and natural in colour. To have two drachms of castor-oil.—Twenty minutes past eleven: Still doing well; pulse fair. To have small quantities of arrowroot and salt beef tea. Six p.m.: Still doing well; has been sitting up in bed in the absence of the nurse.

28th: Greatly improved. Ordered gruel and additional beef-tea. Purged once during the night; evacuation more healthy in appearance.

29th: Bowels acted once last night; complains greatly of hunger. To have three grains of sulphate of quina three times a day.

30th: Convalescent. Ordered mutton chop.

31st: Going on admirably. Bowels acted once to-day.

August 2nd: To have half an ounce of castor-oil.  
4th: Discharged cured.

This was undoubtedly one of the worst cases admitted into this hospital. The recovery was looked upon as miraculous. I could give, did I not fear occupying too much space, ten or twelve other cases quite as bad as this which eventually recovered under the eliminative treatment.

Since the 26th July there have been 67 cases. Of these, 11 were moribund, dying in from ten minutes to eight hours subsequent to admission. This leaves 56 cases, which were thus treated:—

| Cases. | Mode of treatment adopted.            | Deaths. |
|--------|---------------------------------------|---------|
| 11     | (Moribund on admission)               | 11      |
| 2      | Internal administration of strychnine | 2       |
| 4      | Astringent and stimulant              | 4       |
| 50     | Eliminative                           | 17      |
| 67     |                                       | 34      |

The two cases in which strychnine was administered were just in the transition stage between evacuation and collapse. The dose was one-thirtieth of a grain every fifteen minutes, with permanganate of potash and carbonate of soda. The astringent and stimulant treatment was that previously noticed. In the remaining fifty cases I was kindly permitted by Dr. Gee, physician to the hospital, to use castor-oil. With the results I have every reason to be perfectly satisfied. Of these fifty cases, only ten were in the stage of evacuation; and of the remaining forty, nineteen were in a state of the most extreme collapse. I observe in the *Pall-Mall Gazette* of Aug. 4th a statement to the following effect: "The cholera at Liverpool is evidently subsiding, and, as usually happens in such a time, the larger proportion of recoveries is attributed to the mode of treatment, castor-oil having been substituted for camphor and ice." Now, exactly the opposite of this is the case. *The disease is not subsiding; choleraic diarrhœa is increasing rapidly, and the cholera type is more severe.*" It cannot be said that the cases treated on the eliminative plan were milder in character than those treated by camphor, astringents, or ice, for, so far from this being the case, I can most unhesitatingly affirm that they were not only *more severe in character*, but were not, as a rule, prescribed for until collapse had for some time set in. Of the seventeen deaths, two occurred from pneumonia during convalescence; two were cases which had been discharged cured, and were suddenly seized with a relapse; and nine were cases in which there was no radial pulsation, and in which *neither emesis nor purgation could be produced.*

Eight post-mortem examinations were made, and as I consider the results important, I may be excused for giving the particulars of one case in detail.

Case 1.—Maria W—, aged 40, admitted July 31st, at thirty-five minutes past twelve a.m. Has been ill for twelve hours; was seized suddenly with vomiting and purging. On admission was in a state of the most extreme collapse; algid symptoms very intense; temperature in axilla 96°; almost complete aphonia; pulse feeble and faintly perceptible in brachial artery; great thirst; upper extremity covered with cold, clammy perspiration. To have hot bottles to feet and body, and sinapisms to abdomen and calves. Ordered three drachms of castor-oil, two drachms of syrup of lemon, and fifteen minims of chloric ether every hour; hot solutions of muriate of soda and chlorate of potash to be thrown into rectum every hour.—Two a.m.: Oil retained; neither purging nor vomiting has taken place.—Half-past three: Oil still retained; not purged. Three minims of croton-oil rubbed on tongue; friction with croton-oil over abdomen.—Five: Injections returned; no improvement. To continue with oil.—Half-past ten: No improvement; no purgation.—Twenty minutes past twelve p.m.: No improvement. Seen by Dr. Maphother of Dublin.—Twenty-five minutes past two: No improvement; no purging. Intestines stimulated by galvanism, which produced slight vomiting and purging.—Five: No improvement; no purgation.—Ten: Has been continuing in the same state; power of deglutition lost.—Half-past eleven: Venesection resorted to; blood refused to flow. Heart stimulated by galvanism, when a few drops of tarry-looking fluid exuded from right arm.—Forty-five minutes past eleven: Died.

Autopsy, eight hours after death.—Vessels of the right side of the heart and pulmonary artery distended with dark blood; left side nearly empty, containing only a few coagula. The lungs on their peripheral portion were pale and exsanguinated.

\* A reference to the reports of the Medical Health Officer will settle this point.

neous; from the central portions a small quantity of thick, dark blood exuded on section. Hepatic veins and capillaries of vena porta full. Gall-bladder enormously distended. Duodenum almost empty. Stomach contained large quantity of castor-oil; mucous membrane presented towards pyloric end œdematous patches. Peyer's and the solitary glands greatly enlarged, presenting a salmon-roe appearance. Peritoneal coat of small intestines pale, except towards lower part of ileum, where it was of an olive-green colour; this part was full of a remarkably fetid fluid, having a resemblance to bad pea-soup; the mucous membrane of this part was softened and thickened. Colour pale on peritoneal and mucous surface, and nearly empty. Kidneys and spleen natural. Vascularity of brain and meninges slightly increased; structure, so far as I could judge, normal. Arytenoid and epiglottidean muscles livid, and dotted with minute ashy specks.

Case 2.—A man, aged 50. Symptoms on admission similar to last, as were almost also the post-mortem appearances. In particular, the similarity in appearance of the small intestine and its contents was noticed. In four other cases I found almost identical appearances. This condition of intestine, when taken in conjunction with the fact that in none of these cases could purgation be produced, I consider of the greatest pathological significance.

General remarks.—The method of administration of the castor-oil was, in the majority of cases, that advised by Dr. Johnson in his work on "Epidemic Diarrhœa and Cholera." I have found in nearly every instance a wonderful tolerance of this medicine. The most difficult point in the whole treatment of the disease I believe to be that connected with diet, more especially during the stage of convalescence. From want of proper attention to this point I believe four cases relapsed, two of which died, and two recovered under the castor-oil treatment. From having watched the effects of alcoholic stimulants in collapse, I am of opinion that they invariably diminish the force and frequency of the pulse, and augment the symptoms arising from pulmonary obstruction. Thermometry, so far as I could judge, afforded no measure of the intensity of the collapse. In every case the temperature of the body rose one or two degrees after death. The "rice-water" evacuation has not been at all a characteristic symptom. The discharges presented every variety in appearance. The peculiar character of the voice, the *facies cholericæ*, and the incessant thirst, have been the best marked and most characteristic signs. While in many cases the attack came on suddenly and unaccountably, in the majority there were "premonitory diarrhœa" and abdominal uneasiness. The cases have been of every degree of severity. The disease, as a rule, has only occurred in the low-lying districts, where the unhygienic conditions connected with food, filth, misery, overcrowding, and intemperance, exist notoriously. *The eliminative treatment has been most successful.* It has been a success which those only who have seen and compared the relative severity of the cases can appreciate—a success which statistics cannot show.

Liverpool, August 6, 1866.—Lancet

## Proceedings of Societies.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JULY 4TH, 1866.

Dr. BARNES, President.

THE following gentlemen were elected Fellows:—Drs. Yeaman and Tannahill; Messrs. Challaway, Peacock, and Low.

Dr. MEADOWS showed an *Ecraseur* made for him by Messrs. Mayer and Metzler. It consisted of a single wire, tempered in a peculiar way, rendering it stronger than any wire-rope or chain he knew of. He also exhibited a good specimen of the so-called Cauliflower Excrescence, which he had removed by means of the single-wire *écraseur*.

Dr. MEADOWS related a case of

#### HYPERTROPHY OF THE LABIUM.

The patient, 27 years of age, about six weeks after her second confinement three years since, experienced sudden pain and enlargement of the labia. Treatment

was adopted, and in 1864 she was admitted into St. Bartholomew's Hospital, where drainage-tubes were passed through the mons veneris and left labium; but she left the hospital unrelieved. When seen by Dr. Meadows the left labium was the size of the fist, and the whole mons was much thickened, indurated, and brawny-looking. On the 20th of July the entire labium was removed, together with an elliptical portion of the mons. The operation was successful, and left the parts on that side of their normal size.

Dr. NEAL exhibited two specimens of Singular Malformation, showing the influence of maternal impressions on the fœtus in utero in the lower animals—the cow and the mare.

Mr. SHERATON showed a Steel Fillet designed by him to supersede the forceps. It is constructed by combining a rotatory action with the fillet principle. The rotatory action is obtained by pressing upon transverse bars, by which the blades are formed into a loop of elliptical form, having a short transverse diameter of four inches and a quarter, and a long diameter of five and a half or six inches. Mr. Sheraton explained its application, and considered the flexibility and thinness of the blades as important, in allowing ready adaptation to the axis of the pelvis and to the form of the head.

Dr. GRAILY HEWITT thought the instrument highly ingenious, and likely to be serviceable in some cases, particularly when the head was quite low down; but he believed it could not take the place of the forceps in those cases where the forceps is so particularly valuable—viz., when the head is not so low down, and where there is some degree of impaction.

#### ON EXTREME SURGICAL TENDENCIES OF UTERINE PATHOLOGISTS; AND ON THE DIVISION OF THE CERVIX UTERI.

By E. J. TILT, M.D., M.R.C.P.

Dr. TILT deprecated the extreme surgical tendency that seemed to characterize the present epoch. He gave as a proof of this tendency the frequency with which operations have been discussed at Medical Societies, the unnecessary multiplication of surgical instruments, and the warmth with which their invention or modification was supported. He likewise noticed two books which have lately appeared: one, a very important work by Dr. Marion Sims, in which constitutional means of curing diseases of women were almost completely ignored; and another, by Mr. I. B. Brown, in which it was recommended to cure hysteria, epilepsy, and insanity by amputation of the clitoris. Dr. Tilt stated that he had known the division of the cervix uteri to have been frequently performed or recommended in cases where he was able to pass the uterine sound, and he submitted that no practitioner was warranted in dividing the cervix, either for sterility or dysmenorrhœa, when the cervical canal had that width; as microscopic animalcules could find no difficulty in ascending where the uterine sound could pass. He alluded to the difficulty of passing a sound into the virgin womb, which did not interfere with the frequency of conception, in young women, soon after marriage. The author's experience led him to believe that the utility of dividing the cervix uteri had been unintentionally exaggerated. There were no statistics to show that conception was frequent after the operation; and he had frequently been consulted by those who had been operated upon during the last ten years, and who had remained barren. Dr. Tilt argued that there was so great a tendency on the part of the divided surfaces of the cervix to reunite, that the operation was generally useless, unless followed up by dilatation; and he thought that in the majority of cases of uterine stricture dilatation was the safest and best way to relieve dysmenorrhœa and to facilitate conception. He wished the division of the cervix to be restricted to cases where the cervical canal was extremely narrow or the cervical walls very hard, and to cases wherein dilatation had proved a failure, or where there was flooding from uterine fibroids. He reserved his opinion respecting the value of the operation in cases of uterine displacement or of malformation; and deprecated the opera-

tion being resorted to as a kind of *pis aller* in those intractable forms of uterine disease in which relapses depend either on a congenital unhealthy tendency of the organs of generation, or on some deeply rooted constitutional taint. Dr. Tilt mentioned that in three of his patients the operation had been performed without the knowledge of the patients or their friends, and he took occasion to remark that this did not accord with the usually received notions of medical ethics.

Dr. HENRY BENNET thought that Dr. Tilt deserved the thanks of the Society and of the profession for the paper read that evening. Although for the last seven years ill health had kept him out of active practice, he had continued to take the liveliest interest in uterine pathology, and had made himself acquainted with all that had been written and said on the subject. As a result he was deeply impressed with the idea that the therapeutics of uterine disease had taken of late too surgical a direction, and he thought, like Dr. Tilt, that this tendency required restraining, limiting, directing. After a seven years' absence from the debates of the Society, he could not but feel that it was passing strange that he should have to rise as a conservative, and that in the very arena where he had many a time, in former days, defended progress, and where he had been opposed and stigmatized as a rash innovator. When he commenced practice in London twenty-three years ago, uterine therapeutics comprised little else but the treatment of cancer, tumours, prolapsus, and constitutional conditions. The most continued and irrational opposition met his efforts to establish more correct views—to demonstrate that physical means of investigation were as imperatively demanded in the study and treatment of diseases of the uterus as in those of diseases of the heart, lung, bladder, rectum, &c. By degrees, however, more reasonable ideas gained ground, and this senseless opposition to the progress of science was vanquished. Now it had entirely ceased, and had become a mere remembrance of the past. Indeed, as stated by Dr. Tilt, the danger rather appeared to be in going too far the other way, and interfering too much. This seemed probable when a recent surgical work on female diseases, written by a clever, experienced laborious American surgeon, his friend, Dr. Marion Sims, proposed division of the cervix uteri on both sides, down to its vaginal attachments, as a remedy for all kinds of morbid conditions, for various deviations, and for sterility. Indeed the Doctor, in one page, stated that he and his colleague in the Female Hospital at New York, performed this operation five hundred times in two years! Again, many recent writers and operators seemed imbued with the idea that the passage through the cervical canal to the cavity of the uterus ought to be, what might be termed metaphorically, as open "as a carriage door," constantly finding stricture therein, for which they operate by ruthless divisions, if it is not so. He (Dr. Bennet) believed that this view was founded in error, and that the greater part of these cutting operations were not in any respect called for or necessary. He believed also that this error would not be so constantly made were his discovery of a sphincter at the os internum recollected or recognized. This sphincter was a vital contraction of the circular fibres of the cervix at the os internum, similar in function to the sphincters which closed other cavities—the stomach, rectum, bladder. When the cold uterine sound reached it it contracted, and impeded its entrance into the uterine cavity, and a stricture was declared to exist. A wax bougie, No. 4 or 5, on the contrary, its extremity warmed by the hand, and slightly curved to the shape he had described as that of the uterine passages, generally entered with ease. The patent condition of the cervical passages which these authors appeared to consider necessary for conception was not natural, and certainly not necessary for the entrance of microscopic spermatozoa. It must not be forgotten either, in treating of sterility, that in England one married woman in six is sterile; in America, according to Dr. Marion Sims, one in eight. The causes of sterility were very numerous, and were not to be re-

moved merely by cutting a royal road for the spermatozoa. Moreover, these divisions of the cervix healed up, and in a few months the narrowed condition was as bad or worse than ever in most cases. Twenty years ago, at Sir James Simpson's instigation, he operated in many cases, and all but abandoned the operation on account of these relapses. Since then he had generally used very small sponges if he wished to dilate, and had never once had an accident. The attacks of inflammation that had occurred in the hands of others had no doubt been caused by the attempted dilatation of inflamed tissues. The cervical canal ought to be perfectly sound when it was interfered with. In conclusion he repeated that he quite agreed with Dr. Tilt that the uterus is now-a-days too frequently interfered with surgically, and that the indications for operations required better defining.

Mr. BAKER BROWN said he thought the paper was brought forward at a most appropriate time, for he perfectly agreed with the author and with the observations of Dr. Henry Bennet that operations upon the cervix uteri were performed too frequently, and without proper regard to preparatory and subsequent treatment. He was glad to have the opportunity of stating before the Society, in the strongest language, his reprehension of the rashness with which this operation was performed in both the out-patients' department of hospitals and the consulting rooms of the operator. He had always taught that the operation of dividing the os and cervix uteri was one of great danger; and although he had performed it a vast number of times, he had never done so without careful preparatory treatment, and the most absolute rest for two or three weeks after the operation. He thought the danger was also increased by the frequent division of the internal os. For his own part, in all cases of flexions, he simply divided the cervix up to, but not through, the internal os; but in all cases of uterine hæmorrhage or intra-uterine fibroid tumours, he then carried his incision through the internal os. In all cases, immediately after operation, he plugged with oiled lint, and took every precaution to prevent the admission of atmospheric air. He believed the neglect of these precautions would generally account for the untoward results which so frequently followed the operation. He could confirm all that Dr. Bennet had said as to the opposition and persecution he had met with in reference to his treatment of uterine diseases; and when he reflected how triumphantly Dr. Bennet had overcome all his opponents by the truth of his practice, he (Mr. Brown) felt consoled for the opposition he received for publishing the results of his experience on a subject of which he as yet confessed himself to be but a learner. But as he had always, through a long professional career, immediately published any innovation which he had believed to be practically useful, so he would continue unto the end, feeling sure that the majority of the profession would always honestly investigate anything which he might place before them.

Dr. HEAD was of opinion that the expression "stricture of the os uteri" demanded a clearer pathological definition. He never had had the opportunity of seeing after death a stricture of any portion of the cervical canal, and thought the specimens must be extremely rare. He believed that cases of coarctation of the os uteri internum, not dependent upon organic disease or deviations of the uterus from its normal axis, may be attributable very frequently to spasm of the muscular wall of the uterus, especially at the orificial zone. Irritation acting upon the lining membrane of the uterus or cervix reflects itself to the muscular apparatus of the uterus much as occurs in cystitis. He concurred with Dr. Tilt in the belief that in numerous cases operative interference had been premature, and that we should hesitate before we appeal to the knife; indeed that it should be the last resource, and only employed after all constitutional and local measures had been found utterly inefficacious. He (Dr. Head) had lately contrived an apparatus, by means of which the vapour of chloroform un-mixed with air can be passed into the cervical and uterine cavities, and had found chloroform vapour thus injected a

remedy which was likely to afford considerable relief in cases of neuralgic dysmenorrhœa.

Dr. GRAILY HEWITT believed with Dr. Tilt that the operation of incision of the cervix uteri was too frequently, and therefore unnecessarily, practised. He differed from Dr. Tilt as to the indication, for the operation. The uterine sound could frequently be introduced with a little patience in cases where the cervix was for menstruation purposes virtually strictured. He alluded particularly to cases, such as were by no means infrequent, where the canal was distorted and sinuous—a condition arising from thickening of the tissues of the cervix. The mucous membrane might be thickened also; but the chief condition was the irregular hypertrophy of the cervix itself. Then, again, he thought Dr. Tilt attributed too little importance to the effect of the presence of small fibroid tumours in determining flexions and consequent virtual stricture of the cervical canal. He believed many cases of cervical distortion and narrowing could only be dealt with effectually by means of a cutting operation; but the indiscriminate application of the operation was to be strongly deprecated.

Dr. ROUTH said the discussion proved how little the profession was agreed as to either the anatomy or pathology of stricture of the uterine canal. Anatomically, Dr. Savage did not admit a special sphincter at the internal os. Besides, did not circular fibres abound everywhere in the cervix? Then, as to the seat of stricture, it was strange to find eminent men—accoucheurs—fixing stricture almost invariably at the external os; whilst others, quite as eminent, place it at the internal os. Then, again, was it to be said the uterine cervical cavity was never to be cut except in cases of stricture?—and could not the depth of the uterine incision be regulated according to the case. In chemosis of the eye, who would deny the advantage of relieving the congestion by incision? So in uterine disease a mucous lining might be so congested as to require scarification. The hysterotomy effected this most satisfactorily. In parenchymatous uterine congestion itself it also was most beneficial. In conclusion, he could not allow physician-accoucheurs to remain under the stigma put upon them. Obstetric medicine was essentially surgical; and an accoucheur only proved his skill in acting surgically when prompt relief would follow, instead of acting medically when cure would be thereby made very tardy, or not occur at all.

Dr. BARNES expressed his gratification at seeing again amongst them one who had rendered such eminent services to obstetric science as Dr. Bennet. Referring to his memoirs on Dysmenorrhœa and allied affections depending upon a peculiar conoid form of the cervix uteri with minute os externum, the President reminded Dr. Bennet that he had there quoted and adopted Dr. Bennet's views as to the os uteri internum. He believed it was very rarely the seat of stricture, or the source of difficulties requiring division. All his experiences still pointed to the opinion expressed in that memoir, that the os externum was the seat of trouble. And when the peculiar formation which he had described existed, the consequences were very often severe, and even dangerous. He had seen retro-uterine hæmatocele caused by it, and had known examples of young girls dying in consequence. It was absurd to rely upon medicines, or indeed upon anything short of division of the os externum in such cases. As performed by him, the operation had always been safe. Speedy relief followed, and that in many cases which had undergone every other kind of treatment for years before. These were cases for surgical treatment.

Dr. TILT having replied, the meeting adjourned to the 3rd of October.

BREVET LIEUT.-COLONEL JOHN J. MILHAU, Surgeon U.S.A., has been ordered to Hart's Island, N. Y., to investigate and report upon the recent outbreak of cholera at that locality. A corps of civil physicians will cooperate with him in the adoption of such measures as the exigencies of the case may require.

## THE STRAND UNION GUARDIANS.

"THE Brimstone Hotel," or the emporium within the Strand Workhouse, where paupers and nurses sell the medical comforts ordered them by the union doctor, was duly reported on at the last meeting of this board. A committee of inquiry had been appointed, their report was read and adopted, and the matter is officially disposed of for the time. The allegations were proved. Beer and gin have been constantly stolen from sick and suffering inmates of this infirmary, and as constantly sold by the nurses. "The doctor is in a terrible temper to-day, and says you're to have no more beer or gin; but never you mind, I'll talk him over if you keep quiet. Don't say a word or take any notice, or it'll only make him worse." Such was the *modus operandi* of one faithless nurse. The poor wretches who were despoiled did keep quiet, the doctor ordered them stimulants as usual, and it was as regular a thing for the pauper blessed with pence to buy stolen drink as for any Drury-lane toper to turn into a ginshop for his dram.

This was two years ago, the fraudulent nurse is dead, the ex-inmate gives his evidence with freedom, and the committee, while deploring past irregularities, profess that matters are managed very differently now. Paupers might, it is true, sell their own share of liquor, but it was impossible to prevent this, and the nurses are now pure. The report was agreed to, and the unpleasant subject shelved. There is no reason for supposing that the inquiry was not conducted with discrimination and care. The speakers were as moderate in their censures as they were candid in admissions. The pauper witness was complimented on his openness, and thanked for the good service he had rendered in bringing the evils to light. With the exception of an occasional suggestion that as beer and wine had been misappropriated, the board should reduce the workhouse supplies, nothing occurred to offend those anxious for parochial reform. A letter was read from the Poor-law Board, calling the attention of these guardians to the strictures and recommendations contained in the reports of Mr. Farnall and Dr. Edward Smith. The workhouse master reported on this at length, and a strong feeling that something must be done in concession to public opinion was manifest in the discussion which followed. The excited state of the public mind, the prospect of popular indignation being roused, the comments which had been, and the comments which would probably be passed upon parochial acts and parochial shortcomings were frequently alluded to, and it is impossible to doubt that there is an increased and increasing disposition on the part of this and other London boards to conform to the increased humanity of the age. The mere fact of their proceedings being now open to the representatives of the press has done much to chasten their discussions. Indeed there was a touch of burlesque in the clumsy eagerness with which one full-fledged moralist avowed his liking for reporters. "I read all their reports," *naively* remarked this humorous person: "we've nothing to conceal, and I like them to be here, only"—and the qualification was made with a mingled servility and arrogance infinitely musing—"only they won't be faithful, and they don't report fairly."

Not the shadow of a doubt crossed the speaker's mind as to the consummate wisdom, humanity, and discretion of the board of which he is an influential member. The reporters were the only people to blame. Choking sick paupers by the dust from carpet-beating; browbeating a medical officer by threatening to reduce his salary; thefts, cruelty, and neglect in the infirmary, are to be attributed, not to the guardians, but to the troublesome people who have dragged the evils to light. The oily voice and self-satisfied blandness of the speaker made a suggestive comment upon his speech, which is only worth mentioning because the present President of the Poor-law Board seems disposed to adopt a parochial estimate of parochial wants rather than that of independent witnesses. The proceedings of the Strand Union guardians, even when their efforts at improvement are most honest, give convincing proof of the necessity of closer official communication than a mere letter from a government department affords. The evils of overcrowding are admitted, their nursing staff has been strengthened and improved, their paupers had a reasonable petition promptly granted, their out-door relief cases were treated with increased humanity and consideration, a parish apprentice was not bound until the prescribed questions were put, and other matters involving a large expenditure of the ratepayers'

money were temperately discussed. Each of these advances is attributable to the light thrown upon workhouse mismanagement, and in the increased readiness to admit shortcomings may be traced a willingness to adopt a reasonable and comprehensive remedy, if one can be found. The President of the Poor-law Board may perhaps find parochial reform a less difficult task than it would have been a couple of years ago, for the simple reason that those responsible for existing evils have been roused to a partial sense of duty.—*Daily News*.

## THE MEDICAL OFFICERS OF THE GUARDS.

It would be a great mistake to regard the case of the medical officers in the Guards as a mere question of minor military politics. It is a question of public good faith. The *Army and Navy Gazette* acknowledges this week that "both the Horse Guards and the War-office appeared to admit that there was something exceptional in the case, and intimated that it would be so determined." It was, in fact, stated in the columns of that journal, with authority, that a warrant was in preparation which would rearrange promotion of the medical officers in the Guards for the future, but would not have a retrospective action. This was accepted as a fair concession, and it met the just claims of the officers whose interests were threatened. It is now, however, announced in the same journal, by way of apology and defence for the threatened breach of faith which would be involved in the gazetting of Mr. Elkington during the recess, that "the intimation given that the present assistant-surgeons' case was to be regarded as exceptional is not illusory." The brigade promotion is to be applied to them retrospectively, but every assistant-surgeon who would have been entitled to regimental promotion according to the terms in which he entered will be offered promotion as a staff-surgeon on condition of leaving the Guards and entering a line regiment. We should be glad to know on whose authority this is stated. Such an arrangement would be a hollow pretence, and involves a double injustice. It is in no sense an acceptable boon to the medical officers of the Guards, even supposing that they were desirous of being removed from their regiments. In a very short time their pay and relative rank will be improved in some degree by the forthcoming general warrant of General Peel, in which he intends, as he has announced, to adopt the provisions of the report of the Committee on the Position and Remuneration of Army and Navy Medical Officers. At one time such "promotion" as that now indicated by the *Army and Navy Gazette* would have been a boon; and within the last few years it was applied for, but was refused. The refusal was based upon the ground that such promotion would involve injustice to the general medical staff of the army. This objection still applies; and the promotion would now be no boon to the medical officers of the Guards, nor is there any reason to think that any one of them would accept it. But what can be the meaning of this? Why are the interests of ten men to be sacrificed that one may be at once promoted? What sacred promise has been given to Mr. Elkington which requires that all sorts of devices may be put forward to remedy the clearly acknowledged injustice to be perpetrated for his sake? There is no public interest involved in the retrospective change. It does not in the least affect any general administrative question. At least nine out of the ten assistant-surgeons are known to be opposed to it, and most of them will suffer from it. There is no public reason why Mr. Elkington should be promoted out of his turn to the disadvantage of so many others; and if there be any private reason, let him have the option of army promotion, which, it is intimated, will be tendered to the other assistant-surgeons of the Guards, with the fore-known result, that it would of course be rejected. We do not profess to know the inspiration of announcements such as this, but we hope that it does not represent the intentions of the Commander-in-Chief. The pledge given by the military organs, and by the late Secretary at War, was that the warrant allowing promotion should not be retrospective. This is a very simple solution of a difficulty which, really, is only created by the Horse Guards. To carry out that arrangement is to do justice and to keep faith. What is spoken of by the *Army and Navy Gazette* will answer neither purpose.—*Fall-Mall Gazette*.

DR. SCOLLERN finds sulphite of lime a specific in stopping choleraic diarrhoea. The dose is 10 grains.

## THE DISEASES PREVENTION ACT.

THE following are the arrangements that have been made in St. Giles's district for carrying into effect the provisions of the Diseases Prevention Act:—

"The Sanitary Committee of the Board of Works sits daily at half-past nine o'clock, and has already met twelve times. They received each morning a return, compiled from information obtained from their own officers, from public institutions and private medical practitioners, of all cases of diarrhoea and cholera that have occurred in the previous day. The new cases, so far as known, now amount to 600 or 700 a day, in a population of 54,000. Only one case of real cholera is known to have occurred hitherto.

"The Committee have mapped out the district into six sub-divisions, one comprising the greater part of the parish of Bloomsbury, the other five being parts of the poor parish of St. Giles, and each part contains from 6000 to 9000 people.

"In the five poor sub-divisions it is the rule for a family to live in each room. To each sub-division a medical staff is assigned, consisting of one medical practitioner and two assistants. The medical visitor is in all cases young and highly qualified; his assistants are usually medical students who have had much hospital experience, but have no legal qualification.

"Each medical visitor is held responsible for his own and his assistant's work. His pay is two guineas a day; his assistants' half a guinea a day.

"Every morning before nine a.m. the medical visitor makes to the Medical Officer of Health a return of the number of houses and of families visited by himself and his assistants; of the number of cases of diarrhoea, choleraic diarrhoea, and cholera that have been newly met with in the subdivision of the district assigned to him; and of the result of his treatment of old cases of such sickness. It is found that a thousand families can be efficiently visited each day in each of the six districts.

"For the supply of medicines to the poor, the committee have engaged the services of four druggists in various parts of the district, who supply—(1) concentrated medicines for immediate administration by the visitors in their rounds; (2) medicines for all persons presenting prescriptions from the visitors; (3) medicines, made up according to certain prescribed formulae, for persons applying to them at any hour of the day or night without visitors' prescriptions; (4) disinfectants, on the order of the visitors, together with a paper of instructions for use.

"The disinfectant, unless another be specially ordered, is chloride of lime.

"The Committee, after seeking in vain for any other place in their district which could be adapted to the purpose of a cholera hospital, have had a large school building put at their disposal by the rector of St. Giles's. The building has been used for ragged schools, mission-rooms, workmen's reading rooms, and other charitable operations, which will be temporarily suspended or carried on in some neighbouring houses. The school building thus obtained is at this moment being prepared by some few structural alterations to receive cholera patients in a day or two. About forty such patients can be received, with ample space for each bed. The building is isolated, and there is no chance of disease extending from it to the adjacent houses. Arrangements have been made with the Clewer Sisters, who carry on many charitable works in the neighbourhood, to give to the hospital thus extemporized the essential advantage of wise female supervision, and they are at present actively at work with the Committee in getting ready the building, providing nurses, and anticipating every requirement for the sick.

"An engagement has been entered into with the Working Necropolis Company by which the dead body of any poor person dying of cholera shall be removed within three hours of notice given and deposited until interment at the company's mortuary.

"Twenty thousand hand-bills have been distributed about the district urging on householders their responsibility at the present time to keep their premises in the wholesomest condition, urging on the poor the need of cleanliness and watchfulness against diarrhoea, and informing them where to go for medicine and how to get the services of the sanitary staff of the district. The poor are very accessible to the medical visitors, and are very grateful for their care.

"Extra assistance in the sanitary department has been

had for some months. The inspectors of nuisances now examine on the same day into all nuisances reported by the medical visitors, and take the best and most immediate action for the removal of what is injurious.

"To every subdivision of the district a workman is attached to do any disinfection or cleansing that cannot otherwise be conveniently done, and to assist in distributing handbills and collecting returns. The street sewers have been throughout the summer flushed with disinfectants at short intervals. Last winter, in view of the necessity that has now arisen, several important constructive works were made.

"Lastly, the clergy and magistrates, and the parochial medical officers, are affording the Committee every assistance in their power.

"The whole of the arrangements now described are independent of the Poor-law organization of the district.

"When the cholera hospital is complete it will take in all poor patients, whether receiving parish relief or not."

## METROPOLITAN POOR-LAW MEDICAL OFFICERS ASSOCIATION.

THE first general meeting of this Association was held in the Council-room of the Royal Medical Benevolent College in Soho-square, and was largely attended by members—workhouse and district medical officers in almost equal proportions, and representing nearly every part of the metropolis. Dr. Rogers, the President *pro tem.*, occupied the chair. Dr. Dudfield, the Honorary Secretary *pro tem.*, having read the minutes of the preliminary meeting and the names of the members, and stated the steps that had been taken in organising the Association, Dr. Rogers addressed the meeting at considerable length, setting forth the objects of the Association, as contained in the printed rules. He dwelt more particularly upon the necessity of making a great effort to better the condition of the sick poor, and to raise the status of the poor-law medical officers. Considerations of pecuniary remuneration, though important, should be sunk in comparison to the former objects. They were engaged in the noblest work man could be engaged in: they were men of education, and devoted to their work. What, therefore, they should ask for, was increased means of doing their duty to the sick poor. The amount of their salary, which was admitted by Mr. Farnall, the Poor-law Inspector, to be quite inadequate, they would leave to the appreciation and justice of the public. The revelations which had been made respecting the treatment of the sick poor in workhouses had excited a strong public feeling upon this subject. The poor-law medical officers were not responsible for that treatment; on the contrary, they did what they could to obtain more liberal treatment of the sick poor. He thought that one of their objects should be to get the medicines for the poor at the expense of the State. He was glad to find that this recommendation had the support of Mr. Farnall. The objects of the Association were:—1. To obtain for the sick poor chargeable to the State the advantages enjoyed by the sick poor in hospitals, &c.; 2. To obtain life-appointments for all poor-law medical officers, and entire payment of salaries from the Consolidated Fund; 3. To provide a basis for consultation and united action; 4. To obtain an authoritative decision upon all disputed questions relating to duties and extra medical fees; 5. To obtain from the local authorities the provision of all medicines and appliances prescribed for the sick poor, and the employment and payment by the same of qualified dispensers; 6. To address representations to the Poor-law Board by memorial and deputation; and, if need be, to petition the legislature in such cases and circumstances as may appear to render such action necessary. These objects, having been severally discussed at length, were agreed to, as well as a number of rules for the government of the Association; and a Council of twelve members was then appointed. Besides the ordinary members, there will be a second class of members, honorary in character, and consisting of "eminent physicians and surgeons, particularly those connected with public institutions." Portions of the report of Mr. H. B. Farnall, C.B., the Metropolitan Poor-law Inspector, relating to the duties, &c., of the workhouse medical officers, having been read, together with his recommendations for the amelioration of their position, it was unanimously resolved: "That this meeting, representing the poor-law medical officers of the metropolitan district, cannot separate without recording

their deep sense of gratification, inspired by his generous appreciation of their position and services." A copy of the resolution was ordered to be sent to the metropolitan inspector. A vote of thanks to the Council of the Royal Medical Benevolent College for the use of their room terminated the proceedings, which had been marked throughout by a strong feeling of earnestness, moderation, and unanimity.

At a meeting of the Council of the Association held on July 24th, it was resolved unanimously: "That the Council of this Association, having taken into consideration the report of Dr. E. Smith upon workhouse infirmaries, &c., desire at once, and without now entering into any detailed refutation of the various statements to which they shall subsequently refer at greater length, to reiterate their conviction that not less than one thousand feet of cubic space and eighty feet of floor-space should be allowed to each sick inmate of workhouse infirmary wards. They feel it proper to repel without delay the expressed insinuation of Dr. Smith, that the opinion of the medical officers on this subject, which was officially and urgently sought for by a printed document issued by the Poor-law Board, can be set aside as of no value, now that it proves to be contrary to that of Dr. Smith. The Council also express the pain and regret with which they have read many disparaging remarks of Dr. Smith in relation to their qualification, conduct, and position as medical officers. These they feel to be entirely undeserved, unjust, and ungenerous. The Council refer with confidence to the more just estimate formed by Mr. Farnall, who, as poor-law inspector in the metropolis for several years, has had numerous opportunities of knowing the continuous efforts made by the medical officers to improve the condition of the sick poor, and faithfully to perform their duty." It was also determined that Dr. Rogers be requested to present a copy of the resolution to the President of the Poor-law Board.

## Medical News.

**INDIAN MEDICAL SERVICE.**—The Military Secretary, India Office, presents his compliments to the Editor of THE MEDICAL PRESS AND CIRCULAR, and begs to enclose a list of the Candidates for her Majesty's Indian Medical Service, who were successful at the Competitive Examination at Chelsea, in March, 1866, and who have undergone a course of instruction at the Army Medical School, together with the total number of marks obtained at the examinations at Chelsea and at Netley.

India Office, 24th August, 1866.

| NAME.                   | STUDIED AT                           | TOTAL NO. OF MARKS. |

**CHOLERA** in London is fast disappearing. Junod's boot has been used in some cases with benefit to relieve congestion. Small doses of calomel hold their ground, as the best general treatment, combined with injections of bland nourishing fluids into the bowels. The epithelial desquamation of Dr. Lionel Beale is supposed to be a post-mortem change.

THE *Globe* newspaper, in an analysis of the report of

Dr. Edward Smith on London Workhouse Infirmaries, shows that in many of these institutions 800, 900, and even 1000 cubic feet exists for each patient. That "marked cleanliness" is the rule in all the infirmaries and workhouses, as well as paid nurses; so that the late sensational reports are one-sided and destitute of foundation.

**BROMPTON HOSPITAL.**—It is said that on account of the unsatisfactory result of the effort made to send phthisis patients to Madeira, the sanatorium in that island is given up, and the subscriptions for that special fund have been returned to the donors.

**DR. MORELL MACKENZIE** has been elected Assistant Physician to the London Hospital; there was no other candidate, the restrictions of the College of Physicians preventing many candidates coming forward.

**CHOLERA AND CASTOR-OIL.**—A letter in the *Observer* says there have been only 20 cases of cholera at King's College Hospital. The deaths 5 in 14; so that any superiority of castor-oil is doubtful.

**MEDICAL STATISTICS.**—Various statistics on infanticide by Dr. Lankester, as well as some figures of Dr. Farre on cattle plague and cholera, and London "Water Supply," are shown in the *Pall Mall Gazette*, and other papers, to be entirely erroneous and unreliable.

**THE Cholera Mist**, according to Mr. Glaisher's latest revelation, is a species of fog or vapour, but most frequent in cholera times, when the cholera influence is not present at all.

**DR. MARKHAM** has published his first report of his visit to London workhouse infirmaries (the Clerkenwell), which is favourable to the condition of the infirmary itself, except that the patients are limited as to space.

**THE Pharmaceutical body** in England have had a congress, and are crying out for licensed chemists, as Apothecaries' Hall has neglected the subject, and encouraged quackery. A "bill" in Parliament is proposed by the congress to have "chemists" registered.

**MR. GROVE**, President of the late meeting at Nottingham, known by his researches on "Correlation of Forces," whose masterly address on this subject and biological science caused such excitement in that town, is a practising barrister who goes circuit. He does not include nervous action or life in his list of correlatives, as some physiologists are inclined to do.

**THE Sanitary Committee** of St. James's, Westminster, have chained up the handles of all the pumps, and have asked for power to fill up the wells altogether. This proposition, however, has been opposed.

**THE monthly return** shows that the number of paupers in receipt of relief at the end of May was 3·4 per cent. less than at the corresponding period of 1865.

**THE JEWISH POPULATION AND THE CHOLERA.**—From July 28 to August 11 no less than 391 cases had received assistance from the Board appointed for their relief. Scarcely a single case, however, has been noted among the upper and middle classes of the community.

**OFFICIAL VICTIMS OF CHOLERA IN PARIS.**—The St. Antoine Hospital, in Paris, has again lost a resident medical officer from cholera, this being the third sad event of the kind in that hospital. During the epidemic of last summer, Messrs. Cacciaguerra and Mocquot fell victims to their incessant care of cholera patients; and, a few days ago, one of their successors, M. Boussard, was struck by the disease and died in a very short time. All the officials of the hospital attended the funeral, and M. Mesnet, one of the physicians, delivered a very touching discourse on this melancholy occasion.

**CHOLERA.**—Since the outbreak of the epidemic 6619 patients have been relieved with cholera and choleraic diarrhoea at the Queen Adelaide's Dispensary, Bethnal-green, without any letter of recommendation, of which 5129 were relieved previous to the local dispensary stations being opened.

**MERCURIAL STOMATITIS.**—A Spanish surgeon, M. Amekler, thinks that gargling with brandy in cases of

ulcerated mercurial stomatitis is extremely useful, combined with cauterization by means of sulphate of copper. He does not deny the virtues of chlorate of potash, alum, the dilute acids, &c., but he has found, in several cases, the alcohol wonderfully efficacious.

THE Glasgow authorities propose to expend £1,250,000 in buying up the worst parts of the city and improving it.

THE death is announced of Lady Barry in her eighty-eighth year. Her ladyship was the widow of the late Sir David Barry, M.D., and a sister of Archbishop Whately.

ON Sunday last the Bishop of London visited the cholera haunts at the east end of London.

THE daily average of cholera cases in New York is forty cases and fifteen deaths.

PROFESSOR AGASSIZ has returned to Boston from his scientific tour to Brazil. He will visit Europe next year as one of the Commissioners to the Paris Exposition.

By the official returns in the Maïras district of Gaugam the number of people daily fed is 2480. In the last week of June 3000 persons died from starvation in Cutrack alone. Up to the 11th inst. Government had spent £80,840 in relief.

THE sum of 3500 francs has been left for distribution among the sick and wounded soldiers in the hospital at Brescia, by the King's order.

A GREAT number of cases of sudden insanity have occurred in Italy. These cases of madness are attributed to the great political excitement prevailing.

DR. NOAD, having analyzed the water from the four pumps in the Laner and Middle Temple, has condemned the water of the one in Hare-court. He found it to contain organic matter, possibly of an animal origin.

TWO convictions have been obtained under the new Sanitary Act, by the Islington authorities, against owners of house property, for overcrowding and want of cleansing.

THE Austrian newspapers report that typhus is prevalent in the Prussian Army.

IT is stated that there are 258 persons to the square mile in the United Kingdom.

ACCORDING to the latest returns it is stated that, from the commencement of the cattle plague, one animal in every nineteen has been attacked, and to every 1000 attacks 862 animals perished.

LONGEVITY.—In 1864, 98 persons (28 men and 70 women) died who had reached 100 years of age or upwards; one woman dying at 108, and one man at 109.

EDINBURGH MEDICAL STUDENT'S CHRISTIAN ASSOCIATION.—A meeting of this Association was held in the University this week, Professor Balfour presiding. The following among others were present:—Professor Spence, Drs. Handyside, Grainger Stewart, Black, and MacDonald. Letters of apology were read from Sir J. Y. Simpson, Bart., Professor McLagan, and Professor Henderson. The following resolutions were unanimously adopted:—

1. "That in the opinion of this meeting this Association is worthy of all support, and that the students present resolve to promote its objects by all means in their power."

2. "That those members leaving town resolve to make this Association widely known in the districts in which they may be established."

A vote of thanks was then given to Professor Balfour for presiding, and to the Medical Missionary Association for their kind co-operation.

THE BUCHAN MEDICAL SOCIETY.—The fifth annual meeting of this Society was held at New Maud on Tuesday, the 7th inst.; Dr. Anderson in the chair. The subjects for discussion—viz., "Purpura" and "Scurvy," were introduced in an able address by the president, who insisted upon the necessity of recognizing *land scurvy*. The members afterwards dined together, and spent a very agreeable evening. The next meeting is to be held in the same place; Dr. Ruxton in the chair.

NOTICES TO CORRESPONDENTS.

Mr. H. S.—We think you cannot do better than consult the author of the book you mention. You will, without doubt, get the utmost candour from him relative to the case you mention.

BOOK RECEIVED.

Cholera. By J. Shew, M.D., and R. M. Trall, M.D. London: Bacon and Co., Paternoster-row.

Appointments.

- Mr. BATE has been appointed Assistant Medical Officer to the General Hospital and Dispensary for Sick Children, Manchester, vice E. B. Loughnan, L.K.Q.C.P.I., resigned.
- J. G. BURNE, M.R.C.S.E., L.K.Q.C.P.I., L.M., late of Marske-by-the-Sea, Yorkshire, has been appointed third Medical Officer to the High-street Dispensary, Dublin (City), during the prevalence of cholera.
- ANDREW CLARK, M.D., has been appointed Physician to the London Hospital, vice N. Parker, M.D., resigned.
- J. COOPER, M.D., Assistant-surgeon to the London Hospital, has been appointed an additional Assistant-Surgeon to the Royal London Ophthalmic Hospital, Moorfields.
- W. P. FISHER, M.R.C.S.E., has been appointed Medical Officer to the Dartford Union Workhouse, vice W. P. Hoare, F.R.C.S.E., resigned.
- E. C. HADEN, M.R.C.S.E., has been appointed Medical Officer to the Dudley Union Workhouse, vice C. A. J. Thompson, M.R.C.S.E., deceased.
- WM. HOFFMEISTER, M.D., has been appointed Medical Officer and Public Vaccinator for the Cowes District of the Isle of Wight Union, vice J. E. Gibson, M.R.C.S.E., L.S.A.L., resigned.
- R. LIVEING, M.D., has been elected Assistant-Physician to the Middlesex Hospital, vice Murchison, elected Physician.
- DR. P. MANSFIELD, R. N. late of H.M.'s Ship "Amazon," lost in the English Channel, has been appointed additional Surgeon to the Royal Dockyard, Portsmouth.
- C. MURCHISON, M.D. F.R.S., has been elected Physician to the Middlesex Hospital, and Lecturer on the Principles and Practice of Medicine, vice A. P. Stewart, M.D., resigned.
- J. R. NUNN, M.R.C.S.E., has been appointed Surgeon to Warwick Gaol, vice H. Blenkinsop, F.R.C.S.E., deceased.
- S. PARKER, M.R.C.S.E., Surgeon to the Sheffield General Infirmary, has been appointed Consulting Surgeon to the Sheffield Public Hospital and Dispensary.
- P. J. SIMPSON, M.R.C.S.E., L.S.A., late Resident Medical Officer of the Westminster General Dispensary, has been elected Apothecary to the Colney Hatch Asylum.

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

BIRTHS.

- On the 17th inst., at Avon-hill, Midford, Bath, the wife of J. G. Welch, M.D., of a daughter.
- On the 17th inst., at Woodford Wells, Essex, the wife of C. H. Livingstone, F.R.C.S.Ed., of a son.
- On the 18th inst., the wife of Ralph Eddowes, Surgeon, of a son.
- On the 19th inst., at Knipton House, near Grantham, the wife of J. Roberts, M.R.C.S.E., of a daughter.
- On the 19th inst., at Portsea, the wife of Dr. P. Mansfield, R.N., late of H.M.'s Ship *Amazon*, lost in the British Channel, of a daughter.
- On the 20th inst., at Oxford-terrace, Manchester, the wife of J. Lang, M.D., of son.

MARRIAGES.

- On the 7th inst., at St. Mary's Spring-grove, Middlesex, John Young, M.D., Professor of Natural History in the University of Glasgow, to Eliza Leonora Schmitz, daughter of Dr. Leonhard Schmitz.
- On the 14th inst., at Lancaster, Dr. John Harker, to Lucy, daughter of E. Dawson, Esq.

DEATHS.

- On the 25th ult., of cholera, J. W. Ashford, M.R.C.S.E., Assistant-Surgeon H.M.'s Ship *Tyrian*, aged 26.
- On the 2nd inst., at New York, J. Kelly, M.D., son of R. Kelly, M.B., of Fair-street, Drogheda.
- On the 13th inst., W. Harvey, M.R.C.S.E., of South Petherton, Somersetshire, aged 66.
- On the 14th inst., at Lauriston-place, Edinburgh, Wm. Wilkinson, M.D., F.R.C.S.Ed., and Private Lecturer on Medicine, South-bridge.

WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING AUGUST 25TH, 1886.

**London Medical Press & Circular.**

"**SALUS POPULI SUPREMA LEX.**"

PROCEEDINGS OF THE BRITISH ASSOCIATION.

THE meeting of this important Society at Nottingham has been most successful. It is, however, obvious that in a medical journal we can only afford space for a condensed account of the most important papers on those subjects which most immediately interests the profession. The various excursions, *fetes*, and other attractions, by which the public is beguiled into a temporary enthusiasm for science, have been duly described by the daily papers. Be it ours to record, as tersely as possible, some of the more serious acts of the "Parliament of Science," as the Association has been called. These we shall arrange in reference to their importance from a medical point of view:—

PHYSIOLOGY.

President—DR. HUMPHRY.

Secretaries—DR. SPENCER COBBOLD, J. BEDDARD.

Committee—Dr. J. H. Bennett, Dr. Arthur Gamgee, Dr. Kelburne King, Dr. Richard Norris, Dr. W. B. Richardson, Dr. W. T. Robertson, Dr. Dr. Sibson.

Dr. HUMPHRY gave an address, in which he dealt with the general questions of the origin of life and death, and contested the doctrine of Continuity in life—of the origin of species by natural selection.

"On the State of Lime, whether Crystalline or not, in the Egg-shells of Birds," by Dr. J. DAVY.

"On the Physiological Action of Medicine," by Dr. W. SHARP.

"Remarks on the so-called Cattle Plague Entozoa," by Dr. COBBOLD.

"On the Conditions of the Protoplasmic Movements in the Egg of Osseous Fishes," by Dr. RANSOM.—The subject of these rotations or oscillations had engaged attention since the time of Rosconi. By means of diagrams, the phenomena of movement visible in the unimpregnated egg were shown. After water has entered the ovum, a distension of the outer rim and a diminution of the yolk mass itself occur, while the separation of the food-yolk takes place. Then the protoplasmic movements cease, fissile contractions commence, and the general process of yolk-division occurs. The author detailed the results of a number of experiments with various agents, the object of which was to ascertain their action on the rhythmic movements he had described in the yolk.

Mr. F. BUCKLAND elicited from Dr. Ransom the opinion that it was a mistake to pack eggs in damp moss, since they required oxygenation by fresh pure water, and he had found them live longest under that condition.

"On the Colour of Man," by Dr. J. DAVY.—The author enumerated the various shades of complexion and the position in which they were found. The warmer the climate, the less the difference in the venous and arterial blood. The Esquimaux were neither fair nor dark brown, but intermediate. The long, continuous solar effect for one half the year, associated them with the inhabitants of the tropics, whilst their living underground the other half, assimilated them to inhabitants of the fairer countries. He showed that a colder climate favours fairness of the skin. With regard to the Chinese, he ventured the conjecture that their colour might be owing to the imperfect development of blood in the bile. The hereditary colour might pass in course of time into that distinctive of the climate. Of this he gave a variety of instances: and in-

vented discussion on a subject of no ordinary interest in regard to health and beauty.

"On the Sources of the Fat of the Animal Body," by Drs. J. H. GILBERT and J. B. LAWES.

CHEMISTRY.

President—DR. H. BENGE JONES.

Vice-Presidents—Prof. DAUBENY, H. DEBUS, Dr. W. A. MILLER, LYON PLAYFAIR, J. STENHOUSE, A. W. WILLIAMSON.

Secretaries—J. H. ATHERTON, Prof. LIVEING, W. J. RUSSELL, JOSEPH WHITE.

Committee—F. A. Abel, J. Attfield, H. Basset, J. S. Brazier, Dr. Bauer, Grace Calvert, W. Crookes, Dr. John Davy, G. C. Foster, J. H. Gilbert, J. P. Gassiot, J. H. Gladstone, W. E. Heathfield, S. Macadam, T. H. Rowney, H. E. Roscoe, J. Robinson, Peter Spence, Dr. E. Smith, J. Spiller, A. Voelker.

THURSDAY.

This section was held at the School of Art. The President remarked that from the foundation of the British Association, in 1831, no physician had been President of the Chemical Section. For centuries the union of chemistry and medicine has been at one time admitted and at another disallowed; but in the last half-century the discovery of Dr. Bright proved that chemistry is requisite for the detection of a large class of diseases, and that without chemistry these diseases cannot be understood. When the union of chemistry and medicine is perfect, science will show us how to keep or to regain the greatest of blessings, health. Among the harvest of new truths of the last year, Dr. Bence Jones noticed Prof. Frankland's synthetical researches on ethers, and his researches with Mr. Duppa on the synthesis of acids of the lactic series. He alluded to Prof. Roscoe's paper "On the Chemical Intensities of Sunlight," as the direction in which the chemist looks for the climax of all his synthetical investigations—the discovery of the chemical architecture of substances in the vegetable world.—He then proceeded: "A most remarkable discovery has been made by the Master of the Mint on the absorption and dialytic separation of gases by colloid septa: for example, he finds that mixed gases pass through india-rubber at different rates, proportioned to their powers of liquefaction. The oxygen of atmospheric air passes through rapidly whilst the nitrogen is comparatively stopped. The importance of this discovery in metallurgy, and its application to the physiology of respiration and of the passage of oxygen from the blood into the textures, must be apparent to all. It seems but a few years ago when we were taught that the animal and vegetable kingdoms were composed of entirely different kinds of substances. Nitrogenous compounds were said to belong to the animal kingdom; and the vegetable kingdom was said to be formed of carbonaceous matters only. First starch, then woody fibre, then colouring matters like indigo, then alkaloids like quinine, were one after the other, thought to distinguish the vegetable from the animal creation; and each of these substances, or their representatives, have at last been found in animals. At the present time no chemical distinction whatever between vegetables and animals can be made; and except in the mode in which these different substances are produced in the two kingdoms of Nature, no chemical difference exists. Although we are beginning to ask how our present formula for education has arisen, and why it remains almost unchanged whilst all natural knowledge is advancing, and although an entire change in everything except the highest education has taken place, yet public opinion is affected so slowly, and the prejudices of our earliest years fix themselves so firmly on our minds and the belief we inherit is so strong, that an education far inferior to that which a Greek or a Roman youth, say twenty centuries ago, would have received, is the only education fit to make an English gentleman, that I consider it is of no use, notwithstanding the power which this Association can bring to bear on the public to occupy your time with the whole of this vast question. But there is an outlying portion of this subject which personally touches each one of us here present I allude to the present state of education in natural knowledge of that portion of the community who may at

any moment be asked to tell any of us here present what mechanical means should be used to lessen or increase the mechanical actions of the body, and what chemical substances should be taken to lessen or increase the different chemical actions within us when they rise or fall to such a degree as to constitute disease. I will, as shortly as possible, put before you the present education of those who practise medicine. The present higher education for the medical profession consists, shortly, in learning, reading, writing and arithmetic in the first ten years of life. In the second ten years, Latin, Greek, some mathematics or divinity, and perhaps some modern language. In the third ten years, physics, chemistry, botany, anatomy, physiology, and medicine, and perhaps surgery. Looking at the final result that is wanted—namely, the attainment of the power of employing the mechanical, chemical, electrical, and other forces of all things around us for increasing or diminishing the mechanical, chemical, and other actions taking place in the different textures of which our bodies are composed, it is quite clear that the second decennial period is passed without our advancing one step towards the object required; and that in the third decennial period the amount to be learnt is very far beyond what is possible to be attained in the time allowed. If we turn to the lower education, in the first eighteen years of life, reading, writing, and arithmetic, and enough Latin to read and write a prescription, constitute the minimum to be acquired. During the next three years, physics, chemistry, botany, anatomy, physiology, and the practice of medicine, surgery, and midwifery, have all to be learnt, and from this crowding it follows that the study of physiology is begun at the same time as the study of physics and chemistry. In other words, the structure and the foundation are commenced at the same time. The top of the house may be almost finished when part of the foundation has not been begun. What chance is there of any one understanding the action of the chemical, mechanical, and electrical forces in the body, until a fundamental knowledge of chemistry, mechanics and electricity, has been first obtained? What chance has a medical man of regulating the forces in the body by giving or withholding motion, food, or medicine with any reasonable prospect of success, when a preliminary education in these sciences is thought to be of no importance? It seems to me that the only possible way to make the present preliminary education for medical men less suited to the present state of our knowledge, would be to require them to know Hebrew or Arabic instead of Latin, in order that the origin of some of our words might be better understood, or that prescriptions might be written in one or other of these languages. Let me now, for contrast sake, draw you a picture of a medical education, based upon the smallest amount of classical knowledge, and the greatest amount of natural knowledge which can be obtained. In the first ten or twelve years of life, a first-rate education in the most widely used modern language in the world, English, with writing and arithmetic, might be acquired, and in the next five or ten years a sound basis of knowledge of physics, chemistry, and botany, with German or French, might be obtained; and in the following five years anatomy, physiology and medicine, surgery and midwifery. If every medical man were thoroughly well educated in the English language, and could explain the nature of the disease and the course to be followed in the most idiomatic and unmistakable English, and if he could use all the forces in nature for the cure or relief of his patient, and if he could, from his knowledge of chemistry and physics, and their application to disease and medicine become the best authority within reach on every question connected with the health and welfare of his neighbours; and if he possessed the power of supervising and directing the druggist in all the analyses and investigations which could be required as to the nature and actions of food and medicines and as to the products of disease, surely the position and power and agreement of medical men would be very different from that which they now obtain by learning some Latin and

less Greek. At present, so far from physicians possessing more knowledge of food and of medicine than any other class of persons in the community, the analytical and pharmaceutical chemists are rapidly increasing in knowledge, which will enable them not only to understand fully the nature and uses of food and medicines, but even to detect the first appearances of a multitude of chemical diseases. Their habits of investigation, and their knowledge of the nature of the forces acting in the body will gradually lead them to become advisers in all questions regarding the health of the community, and from this they will, like M. Bouchardat, in Paris, become almost, if not altogether, practitioners of medicine. In confirmation of my opinion of the direction in which the treatment of disease is progressing, I may just refer to the cattle plague, which in 1745 was treated by Dr. Mortimer, at that time Secretary of the Royal Society, and therefore one of the most scientific physicians in the country, with antimony and bleeding. In 1866, two chemists, Dr. Angus Smith and Mr. Crookes, gave the only useful suggestion for combating the disease—namely, by the arrest or destruction of the poison by chemical agents. There is yet another point of view in which chemists will see the harm that results from our present medical education. The use of Latin in our prescription requires that the pharmacists should learn at least sufficient Latin to read what we have written. Many errors have arisen and will arise from the dispenser being unable to give the directions rightly. To avoid such mistakes, a portion of the time that ought to be given to the attainment of the highest possible amount of chemical acquirement, and a perfect knowledge of the English language, or some foreign language wherein he might learn the discoveries in chemistry and the improvements in pharmacy of other countries, must be devoted to the learning of Latin, in which the physician writes his directions. All our druggists in England ought to be what they are in Germany and in France, chemists capable of any analysis that might be required of them, and able to satisfy themselves and the medical men that the substances they sell are what they profess to be—pure, unadulterated chemical compounds. No one of my hearers in this Section will consider five years a long time for the acquirement of such knowledge, and until the pharmacists all obtain this education, medicine will be subject to a great cause of uncertainty in the variations in the quality and quantity of the different substances which, under the same name, are obtained from different druggists. Before I conclude, I must apologise to some in this Section who may think that this subject is of no interest to them, by reminding them that none but chemists can judge what the worth of chemical education really is; and I am sure that no body of scientific men exists who are so fitted to judge of the necessity of an education in natural knowledge for those who employ the forces around us to regulate the forces within us as the Chemical Section of the British Association. Last year Prof. Miller said, 'It behoves all who are themselves engaged in the pursuit of science to consider in what way they can themselves aid in forwarding the cultivation of natural knowledge.' I ask you, for the good of science, and for your own good, to exert your influence in the first place, and more especially to effect a change in the preliminary education of all those who intend to practice medicine; so that, leaving Greek and Latin to be the ornaments and exceptions in their education, they may have time to obtain the best possible knowledge of the chemical and physical forces with which they have to deal. I urge this because of my conviction that whenever the most perfect knowledge of chemistry and physics becomes the basis of rational medicine, then, and not till then, medicine will obtain the highest place among all the arts that minister to the welfare and happiness of man."

DR. RUSSELL read a preliminary Report, prepared by Dr. A. Matthiessen, "On the Chemical Nature of Cast Iron."

"On a Proposed Use of Fluorine in the Manufacture of Soda," by Mr. W. WELDON.

"On the Assay of Coal, &c., for Crude Paraffin Oil, and of Crude Oil and Petroleum for Spirit, Photogen, Lubricating Oil, and Paraffin," by Dr. ATTFIELD.

"On the Poisonous Nature of Crude Paraffin Oil, and the Products of its Rectification upon Fish," by Dr. STEVENSON MACADAM.

"On a Phosphatic Deposit in the Lower Greensand of Bedfordshire," by Mr. J. F. WALKER.

"On Ozone," by Dr. DAUBENY.—In the discussion on this paper, Mr. GLAISHER stated that "where there was ozone he found abundant health, and where there was none, a great deal of sickness prevailed."

"On an Extraordinary Ironstone," by Mr. T. L. PHIPSON.

"On a New Process in the Manufacture of White Lead," by Mr. J. P. SPENCE.

"On Disinfectants," by Mr. W. CROOKES.

"On the Oxidizing Action of Carbon," by Dr. C. CALVERT.

#### BIOLOGY.

President—Prof. HUXLEY.

Vice-Presidents—GEORGE BUSK, Dr. DAVY, Dr. J. D. HOOKER, Prof. HUMPHRY, Sir J. LUBBOCK, Dr. P. L. SCLATER, Dr. THOMAS THOMSON, A. R. WALLACE.

Secretaries—J. BEDDARD, W. FELKIN, Rev. H. B. TRISTRAM, W. TURNER, E. B. TYLOR, Dr. E. PERCEVAL WRIGHT.

Committee—Spence Bate, H. B. Brady, H. W. Bates, — Buckley, Dr. Bennett, Prof. Bentley, Dr. Baird, J. Crawford, Sir Walter Elliott, Dr. A. Günther, Dr. Hunt, J. Gwyn Jeffreys, E. B. Layard, E. R. Lankester, R. M'Andrew, Dr. Murie, Prof. Newton, Rev. A. Merle Norman, Dr. Ransom, H. T. Stainton, Dr. E. Smith, Dr. H. Stewart, — Stevenson.

Report on the Extinct Birds of the Mascarene Islands, by Prof. A. NEWTON, M.A.—The Committee appointed by the British Association at Birmingham, September, 1865, for the purpose of assisting Mr. E. Newton in his researches for the remains of the extinct Diodine Birds of the Mascarene Islands reported. Almost immediately after the appointment of the Committee, intelligence was received in England of the very important discovery by Mr. G. Clark of Mahebourg, in Mauritius, of a large deposit of bones of the true Dodo (*Didus ineptus*, L.) in a marsh known as the "Mareaux Songes," an account of which that gentleman has published in the *Ibis* magazine for April, 1866. Several fine series of these bones having been sent to England, some were purchased by the Trustees of the British Museum, and formed the subject of a memoir "On the Osteology of the Dodo," read by Prof. Owen at a meeting of the Zoological Society of London, 9th January, 1866. This memoir is understood to be nearly ready for publication; and will appear, copiously illustrated, in the *Transactions* of that Society. Some other fine series of these bones have, by the liberality of Mr. Clark, passed into the possession of one of the members of your Committee, and a portion of them is now exhibited. Several smaller series of bones have likewise been variously distributed by sale or gift both in England and the Continent, so that numerous museums and collections have reaped the benefit of Mr. Clark's valuable discovery; the importance of which may be better appreciated when it is remembered that previously the only remains of the Dodo known to naturalists were the head and foot at Oxford, the skull at Copenhagen, the portion of an upper mandible at Prague, and the foot in the British Museum. Now it is believed that almost every bone of the bird's skeleton has been recovered with the exception—though that is an important exception—of the extremity of the wing. The attention of Mr. E. Newton has been especially called to this deficiency, which seems likely to be supplied by a thorough and systematic examination of the "Mareaux Songes," or at least of the part of it which has been most prolific in Dodo's bones. That gentleman has accordingly determined to carry out the undertaking so far as may be expedient; but according to the latest accounts received from him he had been obliged to defer commencing operations in this quarter till the expiration of the rainy season, as the marsh still continued to hold much water,

and he expected to be able to do no real good there until next month, when the Committee hope that complete success may attend his excavations,

Report on Dredging in the Hebrides, by Mr. J. G. JEFFREYS.

"Remarks on the Rhizopod Fauna of the Hebrides," by Mr. B. BRADY.

"On the Distribution of Mosses in Great Britain and Ireland as affecting the Geography and Geological History of the present Flora," by Mr. J. SHAW.

"On the systematic Position of the American Prong Horn (*Antilocapra Americana*)," by Mr. P. L. SCLATER.

"On a Remarkable Mode of Gestation in an undescribed Species of Arius," by Mr. W. TURNER.

"On the Food and Economical Value of British Butterflies and Moths," by Mr. O. GROOM-NAPIER.

"On the Causes of the Variation in the Eggs of British Birds," by Mr. O. GROOM-NAPIER.

The PRESIDENT (Prof. Huxley) gave an address, to hear and discuss which the three departments of the Section met in one room. Alluding to the large attendance, he remarked that his intention was simply to give an exceedingly short discourse upon the subject of Biology, and although some discussion would probably follow, as far as he knew there would be no quarrel and no heresy. If this announcement should have any effect in clearing the room, he should be extremely glad. He wished to consider for a short time the object of the science indicated by the new term Biology, and the scope of those persons who pursue it, and subsequently the position which had been given to its various branches in this Section of the Association. Suppose him to be provided with an egg and a bean, he would draw the attention of his listeners to their contents. Neither of them contains anything but an incomplete rudimentary foreshadowing of what they will produce. Imagine the egg incubated, or the seed placed in the ground. After a time, a being full of life and activity, and possessing even mental powers, will come from the egg; the chick will become a fowl. So, too, the bean will become a beanstalk. In the whole set of changes undergone there is a definite order and succession of forms, to which the name Development is applied. In studying each stage of this development, we only study a series of distinct forms. It is only form which is studied in development. The inquirer does not ask how or why these changes take place, but simply what they may be. When our chick or bean has arrived at maturity we have not a homogeneous mass. There are muscles and bones in the one and fibres and tissues in the other. The study of the form of the internal parts is called Anatomy, and it is anatomy whether on a small or a large scale. The size does not affect the nature of the study; it is anatomy whether we deal with parts one inch or one-thousandth of an inch in diameter. He would lay particular stress on this, because some persons had a confused notion on the matter; microscopic anatomy, or Histology, is anatomy. In all this we deal with form. So, in considering the relation of being to being, we observe that the form of an oak is more like that of a beanstalk than it is like a man's; again, a man is more like a monkey than he is like a crocodile. This study is that of Taxonomy, Classification, Systematic Zoology and Botany. Form has still another study, that of Distribution, not only in space, but in time. The life on our earth is not a thing of yesterday, but goes back so far into past ages that the record breaks off ere we find its first commencement. Palæontology is the biology of the past, and a fossil animal differs only in this regard from a stuffed one, that it has been dead ages instead of days. We have, then, Development, Anatomy, Classification, and Distribution, all relating to form, constituting Morphology; its methods are Observation, Classification and Registration. The facts concerning form are questions of force: every form is force visible; a form at rest is a balance of forces; a form undergoing change is the predominance of one over others. How has form come about? how does it commence? how does it end? The question why belongs to Physiology in its broader sense. In a narrow sense it has been used only in regard to the properties of individuals, as we say the Physiology of Man. But there is another physiology, dealing with the causes of life, the foundations of which as a science have been laid by Mr. Darwin, the first man to organize this study. Such is a view of the relations of the various branches of biological science. Two things are wrapped up in it: Form

and Cause. The study of physiology requires great preparation; over the door of the physiological department might well be written, "Let no one enter here who is not a chemist and a physicist." As regards arrangements, practical expediency is all that can be considered. The Council of the Association was alone responsible for the arrangements. If there were such a thing as scientific education in our schools, we might keep our Biological section well together in one room; but as it is there is no chance for this. The stick won't beat dog, dog won't bite pig, and so the old woman can't get home. The university won't recognize natural science, and hence the public school won't teach it to the boys, and consequently all men are not versed in all the subjects of it. Hence the Council have provided a department for the medical physiologists, another for the students of ethnology, as a matter of convenience. The division is not philosophical, but it is expedient. We give off buds like an animal of low organization, but, unlike this animal, we retain the power of reabsorbing those buds.

Dr. HUMPREY (of Cambridge) attempted to defend his university from the charge of indifference to science. He considered physiology the very highest and noblest of the sciences, and thought it was wet-blanketed by the Association. He wished that a separate Section might be formed for it.—D. H. BENNETT (of Edinburgh) agreed with Prof. Huxley, but wished for two equal sections of Morphology and Physiology.—Sir J. LUBBOCK observed that the success of the Physiological sub-section of former years had been like that of the broom-seller, who made a few brooms and stole the rest; the physiologists had got a few legitimate papers, and had stolen the rest from the morphological department.

"On the Teaching of Science at the Public Schools," by the Rev. F. W. FARRAR, M.A.—The author argued that the introduction of scientific instruction into the public school system was necessary on three grounds: first because it called into play a *different* order of faculties in boys who had studied language with success; secondly, because it evolved those faculties in boys who were naturally unsuited for classical training; thirdly, because the schools had ceased to be solely preparatory for the Universities, and were therefore bound to give boys the opportunity of acquiring some knowledge which would be of practical use to them in their future professions. He next treated of the difficulties in the way of carrying out these views. Those difficulties did not arise from the prejudice of public school-masters; but from the conflicting opinions of scientific men; from the absence of any definite and well-considered scheme; from the badness of many existing text books; and from the immense amount of time already devoted to the teaching of the modern languages, mathematics and classics, a term which now involved a very wide range of studies. The author suggested that many of these difficulties might be removed if a committee were appointed by the Association, partly composed of scientific men and partly of masters accustomed to the methods of public schools. He stated that at almost every school something was being done, but that the plans mainly adopted were three: viz., 1. Modern schools in which science was made a part of the course. 2. Occasional and compulsory lectures, of which notes were taken by the boys, and 3. A voluntary system, by which boys were encouraged rather than compelled to make themselves acquainted with various sciences. Rugby is the only school at which science is now regularly and completely introduced, and the author therefore described the system there introduced, and the no less characteristic voluntary system which has been established at Harrow, and is working most advantageously. Finally, the author suggested his own scheme, which was a combination of the voluntary and compulsory systems, for which in the case of many boys ample time could be gained by a wise abandonment of the practice of Greek and Latin composition.

Prof. HUXLEY, said he felt sure that the important question for England was not the duration of her coal, but the due comprehension of the truths of science and the labours of her scientific men.—Mr. TRISTRAM recommended the study of botany for developing the powers of observation rather than chemistry.—Dr. HOOKER thought botany and zoology were the most suitable studies for boys, but they must be taught by thorough men of science.—Prof. TYNDALL told how he had instructed a class of little boys with a lump of sugar-candy how they had listened and been absorbed in interest. He dwelt on the necessity of true

science being taught, and not the nonsense which some persons dignified by its name.—Mr. J. PAYNE animadverted on the use of the term "gerund-grinding" as applied to classical teaching, and charged the men of science who had most urged the value of scientific education with a want of earnestness. If they really were in earnest they would condescend to teach in schools, for it was *their* teaching which was required.—Mr. FARRAR, alluding to the increased labour for boys, which additional study would involve, said he would remove a mountain of hard and useless labour from the boy—his verse-making, and in its place impose a light and pleasing study.

"On the Results of Cinchona Cultivation in India," by Mr. C. R. MARKHAM.—The author gave the details of the success which had attended the introduction of quinine plants into India, in which he himself had been mainly instrumental.

"On the Entozoa of the Dog in relation to Public Health," by Dr. T. S. COBBOLE.

#### ANTHROPOLOGY.

President—ALFRED R. WALLACE.

Secretaries—W. FELKIN, jun., EDWARD BURNET TYLOR.

Committee—C. Carter Blake, George Busk, Dr. R. S. Charnock, John Crawford, Dr. J. Barnard Davis, Robert Dunn, Dr. F. R. Fairbank, Rev. F. W. Farrar, James Hunt, Sir John Lubbock, D. W. Nash, Herbert Spencer, W. H. Wesley, Thomas Wright.

Mr. WALLACE remarked—Anthropology is the science which contemplates man under all his varied aspects—as a animal, and as a moral and intellectual being—in his relations to lower organisms, to his fellow men, and to the universe. The anthropologist seeks to collect together and systematize the facts and the laws which have been brought to light by all those branches of study which, directly or indirectly, have man for their object. These are very various. The physiologist, for example, studies man as a wondrous and most complicated machine, whose parts and motions, actions and reactions, he seeks thoroughly to understand. The comparative anatomist and the zoologist compare his structure with that of other animals, take note of their likenesses and differences, determine their degrees of affinity, and seek after the common plan of their organization and the law of their development. The psychologist studies the mind of man, its mode of action, and its development, compares it with the instincts and the reasoning faculties of the lower animals, and ever aims at the solution of the greatest of problems—whence and what is mind. The historian collects and arranges the facts of man's progress in recent times; the geographer determines the localities of the various races that now inhabit the earth, their manners, customs, and physical characteristics; the archaeologists seeks, by studying the remains of man and his works, to supplement written history, and to carry back our knowledge of man's physical, mental, and moral condition into *pre-historic times*; the geologist extends this kind of knowledge to a still earlier epoch, by proving that man co-existed with numerous animals now extinct, and inhabited Europe at so remote a period that the very contour of its surface, form of its hills and valleys, no less than its climate, vegetation, and geology, were materially different from what they now are, or ever have been during the epoch of authentic history; the philologist devotes himself to the study of human speech, and through it seeks to trace out the chief migrations of nations, and the common origin of many of the races of mankind; and, lastly, the phrenologist and the craniologist have created special sciences out of the study of the human brain and skull. Considering the brain as the organ of the mind, the phrenologist seeks to discover in what way they correspond to each other, and to connect mental peculiarities with the form and dimensions of the brain as indicated by the corresponding form of its bony covering. The craniologist, confining his attention to the skull as an indication of race, endeavours to trace out the affinities of modern and ancient races of men, by the forms and dimensions of their crania. These various studies have hitherto been pursued separately. There has been great division of labour, but no combination of results. Now, it is our object as anthropologists to accept the well-ascertained

conclusions which have been arrived at by the students of all these various sciences, to search after every new fact which may throw additional light upon any of them, and, as far as we are able, to combine and generalize the whole of the information thus obtained. We cannot, therefore, afford to neglect any facts relating to man, however trivial, unmeaning, or distasteful some of them may appear to us. Each custom, superstition, or belief of savage or of civilized man may guide us towards an explanation of their origin in common tendencies of the human mind. Each peculiarity of form, colour, or constitution may give us a clue to the affinities of an obscure race. The anthropologist must ever bear in mind that, as the object of his study is *man*, nothing pertaining to or characteristic of man can be unworthy of his attention. It will be only after we have brought together and arranged all the facts and principles which have been established by the various special studies to which I have alluded, that we shall be in a condition to determine the particular lines of investigation most needed to complete our knowledge of man; and may hope ultimately to arrive at some definite conclusions on the great problems which must interest us all—the questions of the origin, the nature, and the destiny of the human race. I would beg you to recollect also that *here* we must treat all these problems as purely questions of science to be decided solely by facts and by legitimate deductions from facts. We can accept no conclusions as authoritative that have not been thus established. Our sole object is to find out for ourselves what is our true nature—to feel our way cautiously, step by step, into the dark and mysterious past of human history—to study man under every phase and aspect of his present condition, and from the knowledge thus gained to derive (as we cannot fail to do) some assistance in our attempts to govern and improve uncivilized tribes, some guidance in our own national and individual progress.

LOCAL ETHEREAL ANÆSTHESIA.—A series of operations have been performed by M. Demarquay, at the paying hospital of Paris, advantage being taken of pulverized ether. Dr. Richardson's apparatus was employed with a slight modification. Instead of the two india-rubber balls, only one is used, and the air is forced into it by a small air-pump. M. Demarquay says that with the pump an ounce of ether is vaporized in one minute. The pump is worked with more or less energy, according to the thickness of the jet.

### BLOOD-POISONING.

By BENJAMIN TRAVERS, F.R.C.S.Eng.

THE chief difficulty about the use of such a term as poisoned blood lies in the assumption or idea of mechanical admixture, which is not consistent with those tendencies which this fluid exhibits when in contact with any matter, whether fluid or mineral, foreign to the homogeneity of its constituent parts.

The effects of turpentine and certain colouring matters, so soon making their presence known *via* the kidneys, the sensible evidence of the transpiratory process, as detected in certain stages of advanced urinary disease, are ready illustrations of the uses of the absorbent system, which becomes thus charged directly from the mucous membranes of the stomach or kidneys, without any direct cognizance or intervention on the side of the blood. Certain salts, albumen, fibrin, easily become incorporated with the fluid contents of the heart and arteries; but poisons, whether animal or vegetable, if brought into contact in a quantity and with a force sufficiently great to imply admixture, dissolve the blood or arrest its current, but there is no evidence of mixing within the body whilst the heart acts or respiration is maintained. The nervous agent has offered an apparently ready method of explaining the course and action of many deleterious compounds. The intimate and immediate power of appeal, which lies alike, both with the heart and nerve centres in circumstances of sudden distress, is universal; but this conducting agency can only act on texture, not on the fluid contents of the heart and arteries. Lastly, has any reliable authority ever seen pus globules in the circulating blood? Pus, we know, may be stained or smeared with the colouring matter of the blood *extra vasa*, but many remain entirely sceptical as to a true pyæmic poison, which is not to be wondered at when one reflects upon the elaborate arrangements which are made by the natural surgeon for the production and discharge of matter when or wherever this form of degeneration is about to take place.

There are many occasions upon which albumen will be found to be present in the urine, which are marked by the purely functional character of the complaint prevailing in the system at large during the continuance of such a symptom. Mercurial remedies immediately promote the advent of albuminous deposits in the urine in some individuals. Nay, this occurrence is so frequent that some physicians hardly admit the fact to be exceptional at all.

In diseased states of the blood, such as albuminuria, there is a loss of relation and homogeneity, but we do not find the loss of its albumen supplied by any disposition to admit the presence of other and foreign ingredients in the sense of admixture or new combinations. The objections to blood mixing within the body are both vital and chemical, and such a proposition would appear to be alike unphilosophical and untrue.

Again, take the case of the dog poison. Is it conceivable that the virus actually invades the circulation either before or after the occurrence of symptoms? The unhappy subject of this fatal disorder remains perfectly well until the restlessness and spasm commence. Thenceforward the symptoms are all on the side of the nervous system, which, in vain, makes its appeal in a secondary sense to the circulation to correct the incessant irritation of the nerve centres. If spasm could be allayed, the symptoms would subside. It is well known that the excision of the wounded part at any period prior to the commencement of the symptoms is efficacious. This was the opinion of Cline, Sir Astley Cooper, Youatt, and others, and is still maintained by living authorities. Surely, if such be the fact, the blood cannot be regarded as slowly absorbing a poison during a long period of incubation.

On the whole, it is here suggested that no poison, as such, ever becomes incorporated with the blood. The symptoms on these occasions are due to contact alone, not admixture.

The functional nature of the disease, termed cholera, is gathered from the fact of its sudden and capricious mode of attack, from the aspect of causes which are known to promote its outbreak in localities, and amongst individuals not suffering from other diseases at the time.

The state of the atmosphere, the fever, the specific form of the "flux," the symptoms recorded as uniformly fatal, even if the patient survives the period of "flux," finally, the dissolution of the blood itself, are all, in their beginning, vices of function, not of organisation.

### CLINICAL REMARKS ON THE TREATMENT OF CHRONIC DYSENTERY.

By HARRY LEACH,

RESIDENT MEDICAL OFFICER OF THE "DREADNOUGHT" HOSPITALSHIP, ETC.

THE annals of Anglo-Indian medicine have, during the past few years, given us very full and complete reports of acute dysentery, with equally full details of treatment. The results of the latter have now reached to a tolerable successful issue, and as China and the East Indies are the great centres for this disorder, its symptoms and pathology have been there studied by many medical men with great care and labour. It is now indeed declared, with some amount of confidence, that this very serious intestinal malady may, in its incipient and acute stages, be completely influenced by curative agents. But the labours of our brethren in the East have as yet failed to give any aids as to the treatment of chronic dysentery. Scores of these patients are annually brought home to us belonging to both services, and in large numbers from the mercantile marine. During the last three and a half years no less than 228 patients, suffering from chronic dysentery, have been admitted into the *Dreadnought* Hospital Ship, and it is probable that the Army Medical Reports could furnish us with a list equally large in proportion, among the vast numbers of those annually invalidated from our Anglo-Indian forces. The pathology of the disease is now very well understood, but published particulars as to its treatment are singularly and surprisingly scanty. For as our newest works on medicine give many and satisfactory remedial agents for the arrest and cure of acute dysentery, so, when the chronic stage is mentioned, no clear line of action is indicated to the reader. It is clear that many drugs, particularly useful in the acute stage, fail utterly when the disease has become chronic, and indeed appear, in many instances, to do more harm than good. The treatment of true chronic dysentery will probably always be mainly confined to the practice of a few medical men connected with the army and civil hospitals instituted for a special class; but some cases of this disease must occasionally be seen by general practitioners, as Anglo-Indians, when they retire from work, return more or less each to their own haunts and homes. Thus, the treatment of chronic dysentery is well worthy of attention, in that few other disorders are so tedious, and so little amenable to what we are accustomed to call definite therapeutic aids. I can confidently assert that in the practice of this hospital, no other disease has been treated with so great a variety of drugs. Powdered ipecacuanha, simple and compound, opium, logwood, catechu, and other vegetable astringents, mineral acids, diaphoretics, calomel, castor-oil, and other products of the Pharmacopœia whose name is legion, have been fully, and, I believe, fairly tried. Poultices, blisters, enemas, and suppositories, have been each and all extensively used, and the benefits from direct stimulants thoroughly tested. Of medical cases admitted into this hospital, no other disease, except scurvy, produces effects so thoroughly debilitating and exhausting, for we must include in those effects, hepatic abscess, ascites, and other minor ills, as well as peritonitis, that

occasional and commonly fatal termination of chronic dysentery. But, nevertheless, the subjects thereof are tenacious of life to a surprising extent, though they may be said, in common parlance, to exist rather than to live. Cases are brought into the *Dreadnought* unable to stand, with voices reduced to a whisper from excessive debility, victims of a disease dating back eight, ten, or twelve months. The hardships inevitably incidental to a long voyage have of course done much to produce this exhausted condition. This latter cause being removed, these patients speedily arrive at a certain stage of improvement, and at this stage they remain for days, weeks, and months. Many die, for the mortality in this institution from chronic dysentery averages about twenty per cent. of the cases admitted. Many, on the other hand, cling to life successfully, and after a continued residence here, amounting in some instances to little short of a year, are discharged from the ship in a state of comparative health. Such cases give a degree of encouragement known as to few other maladies of a chronic kind, and it is well worthy of consideration as to how this desirable, if only occasional, result, can be most surely and most frequently obtained.

The pathology of chronic dysentery is, in influencing treatment, chiefly confined to the simple fact, that ulcers in variable numbers, and equally variable stages, exist along the course of the large intestine. They may be large, few in number, and may exist only near the caput coli. They may be many in number and small, and if this be the case, they are generally scattered pretty equally over the whole course of the large intestine. They may penetrate only the mucous coat of the bowel, or may burrow so deeply through the middle and into the external coat, as to produce an hourly risk of perforation and consequent peritonitis. But be the numbers and state of the ulcers what they may, putting minute and impractical considerations aside, it is clear that our endeavours must be mainly, if not wholly, directed to the giving to these ulcers a favourable opportunity of healing and cicatrization. And here we come to a consideration of the value of those remedies mentioned above. Having regard to the very large number of cases admitted into this hospital, and being sure, from personal observation, that drugs have had a fair and impartial trial, I am compelled to arrive at the conclusion that in cases of chronic dysentery (if the disease be of more than three months' standing) very little specific good can be done by any of the so-called remedies just mentioned. The only drug that can be said to have produced a definite amount of relief in any number of cases is the compound powder of ipecacuanha, and I am by no means prepared to give a very decided opinion about its efficacy. A dose of castor-oil and laudanum given occasionally, often assists the evacuations, and affords relief from tenesmus. Beyond these, the extent of belief in drugs no further goes. And hence it may be said and reasonably maintained, that, as chronic dysentery may recede from the path of recovery by meddling and muddling medicine, so we may medically enjoy and employ rest in these cases as confidently and as happily as does Mr. Hilton in "Accidents and Surgical Diseases." And rest should mean not only absolute quiet for the body, but for the bowel also. The influence of this single condition is marvellously shown in many cases admitted to the *Dreadnought*, the progress of which cannot but lead us to refrain from meddling with the accomplishment of a process that simple quietude has evidently caused to begin. In analysing a list of fatal cases, it is found that half die from exhaustion, no other lesion except extensive ulceration along the colon being discoverable. The other moiety of cases is hastened to an end, by complications of bronchitis or cirrhosis, hepatic abscess, or peritonitis. As therefore our efforts should be directed to the sustentation of the system until nature has accomplished the healing process, it is particularly necessary that care should be used in the choice and administration of diet. Milk, beef-tea, and eggs, in small and oft-repeated portions,

should form the staple of the patient's food for some weeks after admission, varied occasionally by rice, arrow-root, or any other good invalid cereal. Strict quietude in the horizontal position cannot be too strongly insisted upon. If much pain exist it may be relieved (and that without the use of opium) by light and warm applications to the abdomen. The use of stimulants is, I believe, still an open question among most practitioners; but experiences gained at this hospital lead to the conclusion that they should, as a rule, be entirely avoided. An extra allowance of good beef-tea will do far more to sustain the patient than wine or brandy, howsoever given, and I am sure that in many cases, the latter are positively injurious. A placebo must, of course, be prescribed, for as there are few, if any, cases so tedious, so none require more encouragement by all the arts that influence the mind in the conservation of the body. A month, or two, or three, may elapse, with little, if any, signs of change for the better. In many cases a fatal result disappoints our best expectations, but they who, having lingered the longest, at length end well, are those with whom therapeutics have had little or nothing to do. The most favourable results can, of course, yield only a condition of comparative health, which any imprudence as to change of clothing or diet will speedily disturb and destroy. But when men, after months of probationary slop-food, reach successfully to the stage of beef and mutton diet, we discharge them as convalescents, with a good hope to them of a renewal of the lease of life. Good and gentle nursing is of paramount importance, for the vital powers are so feeble, that any risk of bed-sores must be most scrupulously avoided, and would almost invariably precede a fatal result.

The tendency of the foregoing remarks may be condemned as too totally abandoning all therapeutic aids, but they will effect the purpose of the writer, if only they assist to propagate a plan of treatment that will allow cases of chronic dysentery to be cleverly nursed and fed, rather than actively stimulated and physicked.

---

ON THE

MEDICAL USES OF SULPHUROUS ACID GAS.

By JAMES DEWAR, M.D., Kirkaldy.

---

In a village which stands upon a steep incline, and where fever had made its appearance, a boy of fourteen was taken with headache, &c., and upon the third day of his illness I was asked to see him. I found him evidently *in* for an attack, but without any prominent symptom demanding special interference. Next day, I was surprised to find him almost comatose, with irregular pulse and some other indications of ominous import. Upon careful investigation of the premises, I discovered in *ere* of the house, that *three* piggeries *up-hill* of my patient, each contributed to form a small stream of pestilential liquid, which found its way by a back door to a closet within six feet of the boy's bed, and attached to one of these was a dung-hill, the deposit of the refuse of a family in which the epidemic had found a resting-place some weeks previously, and where for weeks afterwards the disease lingered. The obvious course was to remove the nuisance, but here the old difficulties about "middens" presented, themselves, although, in this case, I am glad to admit that they were all but insuperable. I made a compromise, therefore, that a crucible should be set in the offending closet, and that sulphur should be kept burning therein night and day, and I made the due fulfilment of this promise the condition of my continuing attendance upon the case. With the exception of having his hair cut, cold applications to the head, and a simple laxative, no other treatment was adopted, yet within twelve hours consciousness returned, was never again impaired, and the ordinary stages were rapidly gone through, so that on the twelfth day the convalescent was by the fireside. The preven-

tive measures were continued for a fortnight thereafter, and the disease spread no farther in the family. Next door where the process was sneered at, the fever had possession of the premises for three months.

Another case of equal interest has been communicated to me. An elderly man, a master-carpenter in the country, had recently returned home from waiting upon two sons and a daughter-in-law, all of whom had died of "typhoid fever." His home is at an inland hamlet, about thirty miles distant from the infected locality, and within a few days of his return he was laid down with fever. A day or two afterwards the medical man was sent for, and he found that, meantime, a female inmate had sickened also. This naturally gave rise to great alarm, the more so that a number of the carpenters who worked there boarded with their employer. "Sulphurous fumigation" was at once resorted to, and perseveringly carried out by an energetic neighbour with the most satisfactory results—viz., speedy recovery of the patients and extinction of the epidemic.

Ephemeral and catarrhal fever are at once cut short by inhaling the "fumes," while their soothing influence in "scarlet fever" encourages both patients and attendants to frequent repetition of the process. In one family where I attended there were five children under scarlatina at the same time, and the fumigation was given in charge to the father, who was most assiduous in his attention to it. The room was filled almost every hour, and was scarcely ever free from a taint of the disinfectant. The repeatedly observed sedative effect was, in this case, satisfactorily tested; for, especially during night, whenever the inmates showed signs of restlessness, my friend gave them an extra dose, with the invariable effect of inducing quiet and sleep.

In this, as in typhoid fever, it has an undoubted power of both mitigating the severity and shortening the duration of the illness. And I have no hesitation in saying, that to its adoption, accompanied by the diligent application of "sulphurous acid" to the "tonsils," both in scarlatina and diphtheria, is due the merit of having rescued several individuals whose general condition otherwise was unpromising in the extreme. And I may add that, although it may be in some measure attributable to good fortune, while I have had no fatal case of scarlatina during the late epidemic, neither have I seen, out of more than twenty cases, a single instance of "secondary complication."

In "diphtheria" my experience has been equally satisfactory.

"Hay fever" has been checked, and at once, by this simple appliance; and several cases of "hospital gangrene" can now be instanced, in which the morbid action was immediately arrested, and this quickly followed by marked change for the better in the condition and appearance of the wound. This last, besides being of itself interesting, afforded an opportunity of testing the comparative merits of "carbolic" and "sulphurous" medication; and, accordingly, it was found that after the former had failed to give the desired relief, S. A. G. was still able to achieve the happiest success over the enemy.

The application of sulphur fumes to the relief of aching bones, as in "gout and rheumatism," has been so fortunate as to revive the old-fashioned belief in its virtues, and to establish its title to be considered a trustworthy resource, which, from its simplicity, is equally within the reach of "rich and poor," and can be entrusted to the management of the most innocent domestic.

A gentleman, long a martyr to gout, was threatened some weeks ago with a severe attack. When I saw him the storm was just about to burst, and he was looking forward with horror to the ordeal through which he was about to pass. It just occurred to me that, as sulphur baths had proved useful in such cases elsewhere, why might not we upon this occasion bring the "mountain to the prophet" by improvising a sulphurous vapour-bath in the chamber. I accordingly had the room filled with

"fumes," and desired that a set of bedclothes should be hung up in a dressing-closet, and then to be fumigated for an hour or two until they had become saturated. This was most efficiently carried out, the clothes were spread over the patient, who shortly afterwards fell asleep. He became bathed in perspiration, slept for many hours, and awoke with his acute symptoms greatly mitigated.

In rheumatism, likewise, this mode of management has given relief in every case where I have heard of its having been tried, the sedative properties of the agent employed soothing the pain and promoting a tendency to sleep.

I trust that these facts will prove sufficiently definite to my professional brethren to warrant their recommendation of the system to extended trial, being fully persuaded that no one who intelligently and determinedly carries it into practice will ever have cause to regret his having been induced to do so.

Kirkaldy, August, 1866.

## SUCCESSFUL CASE OF AMPUTATION OF THE LEG.

By S. K. CRAUFORD, M.D., L.R.C.S.Ed.

R. H., æt. 45, states his case as follows:—When about 15 years of age he slipped and fell when coming down stairs, and his left knee struck against the wall. Inflammation ensued in the joint, which was leeches and blistered without any permanent benefit. He lay thirty-three weeks, and from that time until the date of the operation there were, to use his own words, "three running holes" in the knee. The disease continued to advance, and ultimately the femur became involved for about two-thirds of its length, caries having set in and eaten right through the shaft above the condyles.

He was admitted into the Armagh Infirmary without receiving any benefit or alleviation from the excessive pains which he suffered, excepting, of course, what good food and rest afforded him, as there was no possibility of anything been done for him except the removal of the leg. This was considered injudicious, as the bones might have been diseased to whole length, and the man's strength was greatly reduced. When sent for to see him subsequently in his own house at Tandragee, I made a thorough examination of the chest and abdomen, and found all the organs sound and in healthy action. I therefore concluded that amputation was called for, and hoped by good food, &c., to support his strength and get him over the shock of the operation. I, with my own assistant, having administered chloroform, amputated at the upper third of the femur by the long anterior and short posterior flaps. On the third day union by the first intention had taken place in the incision, excepting at the angles, which showed healthy pus, and on the sixth day granulations were formed at the angles.

I was obliged to give him as much as thirty ounces of wine daily for the first six days, and as much beef-tea and new milk as he could take. I administered a chlorodyne draught each night, and during the day three to four doses of tinct. cannabis ind. to relieve pain till after the fourteenth day. During all the time the tongue kept clean, and the pulse, which was 120 to 130 at first, gradually sunk, and became fuller, to 90, and he was completely recovered of all œdema of the stump in seven weeks. The results of this case have shown that the femur was not involved for its whole length—a thing most remarkable when we consider the duration of the disease and ill health of the patient. It was also remarkable the rapidity with which the stump healed, and how quickly he recovered from his emaciated condition caused by putting off the operation till the eleventh hour. The patient is now attending to his trade, that of a shoemaker, which date is only nine weeks since the operation.

Tandragee, August 17, 1866.

## A CASE OF OVARIOTOMY.

Communicated by WM. CARTER, M.B., B.Sc., LL.B.Lond., F.R.C.S.I.

It is with the concurrence of the operator, Dr. Albert Walsh, that I forward to THE MEDICAL PRESS AND CIRCULAR the following sketch of a case of ovariectomy, which, though ultimately unsuccessful, may not be without interest, and perhaps not even without encouragement, to those surgeons who regard with favour the principle of the operation. It may be that a faithful record of unsuccessful cases, and of the circumstances that led to their being entered upon, would be more beneficial to the interests of this surgical proceeding, which even yet has not entirely outlived the opprobrium early heaped on it, than to allow them to drop unnoticed by the profession at large.

In the present instance it will be seen that the removal of the tumour was undertaken with but a faint hope of success, a hope, however, which was sufficiently strong to outweigh the only other alternative left, namely, that of a speedy and painful death, without its accomplishment.

The patient, an unmarried lady, aged 46, had suffered from an ovarian tumour for more than three years. It was tapped for the first time by the late Mr. Smyly in the beginning of October, 1863. The cyst, slowly refilled, and was again tapped in February of the year following, subsequently to which the operation was repeated eighteen times by Dr. Carter, the patient up to within a short time ago continuing to enjoy excellent health. Ovariectomy had been proposed on more than one occasion early in the disease, but had been declined. So soon, however, as the health began manifestly to give way, and it became evident that life could not last longer than a few months unless further measures were adopted, the lady consented to a consultation being held as to the advisability of any attempt being made radically to remove the disease. Dr. Walsh then kindly saw the case, with Dr. Carter, and after a very careful examination, agreed to operate, if the patient wished, first of all representing fully the great risk that would be incurred by the operation, but the certainty of a speedily fatal issue if it were not attempted. She decided on having it performed.

Her condition, though discouraging generally, still presented some grounds for hope. Thus, she looked forward to the result, whatever that might be, with great calmness. Then, again, though much emaciated, she was entirely free from any organic disease of heart or lungs, and although these organs were considerably pushed upwards by the tumour, their action was natural and easy. Throughout the entire disease, indeed, there had never been dyspnoea, palpitation, or any other functional derangement of the thoracic viscera. There was no trace of albumen in the urine. The greatest girth of the abdomen was 46 inches; the distance from umbilicus to pubes, 14; from the same point to either ilium, 17. The uterus was central and freely movable. On directing the patient to take a deep inspiration, or to throw the body forward, when she was propped up in the bed, the abdominal muscles were found to be motionless along the middle line in front; a sensation of dragging was complained of at the upper part of the tumour, just where the clear percussion sound pointed to the transverse colon; and a similar sensation was experienced on the left side, where a dull sound indicated the spleen. Adhesions in all these places were therefore diagnosed. Moreover, from the extreme readiness with which a very slight percussion was transmitted, so as to be clearly appreciable on the side of the abdomen, opposite to the spot at which it was made, great thinness of the cyst wall was apprehended by Dr. Walsh, an opinion of which the correctness was only too strikingly demonstrated during the operation, as the cyst was twice broken through by the application of but very slight force before it could be separated from the adhesions which united it to

contiguous parts. These adhesions, though extensive, were almost entirely limited to the situations in which they had been diagnosed.

A short course of tonic treatment was adopted previous to the removal of the tumour, during which, as it began to cause much discomfort from its weight and tension, Dr. Carter drew off about four quarts of fluid. This afforded great relief, and enabled the patient to enjoy refreshing sleep for several nights immediately preceding the operation, which was performed by Dr. Walsh on the 1st or August. Drs. Richardson, Barton, Quinan, and Morgan assisted. There were present also Drs. Ringland and Head. Dr. Carter having given chloroform, and all other preliminaries having been carefully attended to, the operation was commenced by an incision,  $2\frac{1}{2}$  inches long, being made in the median line of the abdomen, commencing one inch below the umbilicus. The peritoneum was quickly dissected down upon. Here, however, the adhesions were so close that the director, on an attempt being made to insinuate it between that membrane and the cyst, ruptured the thin wall of the latter, and permitted the escape of a very little fluid. Directly this occurred, Dr. Walsh, seeing the impossibility of tapping by means of Mr. Spencer Wells's trocar, as he had intended to do, enlarged the opening thus made by the director, and allowed part of the contents of the tumour to flow out. None of the fluid, however, owing to the adhesions, found its way into the abdominal cavity. The separation of the cyst from the peritoneum was then easily effected by the fingers, Dr. Barton raising the freed edges by means of two vulsella, which Dr. Walsh had inserted into them. These supplied the place of the toothed springs attached to Mr. Wells's canula, which could not be used, and like them served to prevent any escape of fluid. As there was not sufficient space afforded by the original incision for the complete introduction of the hand, it was extended upwards and downwards so as to make it when completed five inches long. The hand then was passed into the abdomen, and, without much difficulty, the adhesions which existed between the tumour and the spleen on the left side, the transverse colon above, and several coils of the small intestine posteriorly, were overcome, not, however, before the thin cyst had a second time given way—on this occasion beneath Dr. Walsh's fingers. The part where the rupture occurred was, however, so instantly seized and elevated that the abdominal cavity was still kept free from contact with the contents of the tumour. After this there was no further difficulty, and in the course of a few minutes from the commencement of the operation the entire mass was turned out, and the pedicle, which was of a fair average length, secured by clamps, and then divided. Then for the first time a second cyst was discovered. This was lying low at the posterior part of the abdomen on the left side, where it had been doubtless kept down by pressure of the larger tumour, which took its origin from the right ovary. At the first view it presented very much the appearance of a piece of inflated colon, a constriction partially dividing it into two chambers. This constriction probably indicated the site of a septum, which, previously to its absorption, had made the tumour bilocular. There were no adhesions. The three pints of fluid which it contained were evacuated by Mr. Wells's trocar and canula and the pedicle easily secured. Very little blood had been lost; two or three small clots only requiring removal. This was effected by means of soft warm sponges, which were carefully passed among the abdominal and pelvic viscera. The edges of the wound were then brought together by means of four superficial and three deep points of silk suture, and the patient removed to a well-warmed bed. A suppository containing two grains of opium was administered, and the patient allowed to drink a small quantity of hot brandy and water. In a half an hour moderate reaction set in, the pulse rising to 108, and the skin becoming covered with a warm perspiration. Pain of a dull aching character was complained of, which, however, wore away as the evening drew on—the operation having

been completed by twelve o'clock noon. During the remainder of the day nothing but small quantities of iced barley water was given, while at night a morphia draught was taken, which gave a good night's rest. On the following morning the pulse was 96, the skin still gently perspiring, the tongue moist though white, and all pain gone. For the first four days everything went on well. Barley water, gum water, and well boiled sago, were given, with ice *ad libitum*.

Some slight irritability of the stomach appeared on the third evening, but was readily allayed by a morphia draught. In addition to the other nourishment, regulated quantities of chicken-broth and brandy-and-water were given on the fourth day. On the morning of that day, too, the plasters were for the first time removed and the incision examined. It was well united and free from any signs of irritation. Two of the stitches were removed. The pedicles were hard, dry, shrivelled, and free from any disagreeable odour, though to obviate any that might have arisen, small bags containing powdered vegetable charcoal had been placed in the lower part of the bed and over the clamps. Until the morning of this day there had been but very little urine secreted, but as this was always the case for the first three days after every tapping, it did not excite much apprehension. Now (*i.e.*, on the fourth morning) it was much increased in quantity and presented a more natural appearance, becoming clear, and losing the heavy odour which had marked it. Towards the evening, however, it became turbid again and contained mucus, and its secretion was attended with considerable irritability of the bladder. Hot poultices were immediately applied to the perineum, and lenitive drinks and ice given, by which means the symptoms were mitigated. The clamps, though somewhat retracted, appeared to exert no pressure on the pelvic viscera, so that they were allowed to remain. On the fifth morning the patient seemed less cheerful than usual, though she said she felt very well and quite able to get up if she could be allowed to do so. In the after part of the day, however, a dull pain in the back came on, and by degrees the tympanitis, of which this was the first indication, became distressing. The long tube was used, but with no relief, and hot poultices, with turpentine liniment, were assiduously applied to the whole abdominal surface. Slowly, in spite of a free exhibition of stimulants, the powers declined, and the patient died at six o'clock in the afternoon of the sixth day after the operation.

A post-mortem examination was made after forty hours. By that time decomposition had commenced, and the edges of the wound, which had now opened at the upper part, were very dark. The large intestines were greatly distended, yet neither they nor the small intestines presented much sign of acute inflammation, a little discoloration of the portions to which the cyst had been adherent being all that was perceptible. The fundus of the bladder was red and injected, but otherwise the organ was healthy-looking. The remaining abdominal viscera presented their normal appearance. The pedicles—from which the clamps had been removed, as well as the remainder of the stitches from the wound on the sixth morning—were lying firmly secured by their ligatures in the pelvic cavity.

The weight of the two tumours together, when empty, was three pounds and a quarter, the smaller one weighing of this five ounces. Springing from a portion of the inner surface of the wall of the larger cyst was a great number of secondary smaller cells, the majority of which were filled with a clear gelatinous fluid of much greater density than that of the general contents, while in some few it had all the appearance of pus. There were a number of circular patches of hardened lymph also, from the size of a shilling to that of a half-crown, scattered over the inner surface of the larger cyst.

~~~~~  
 ACCORDING to the latest accounts the cattle plague has appeared in 464 localities in the county of Cheshire, and cases are reported from 13 townships.

A SELECTION OF CASES FROM THE
UNPUBLISHED MSS. OF F. McEVROY, M.D.,
BALBRIGGAN, COUNTY DUBLIN.

By EDWARD WM. A. O'BRIEN, M.R.C.S., L.K.Q.C.P.I.

A REMARKABLE CASE OF COMPOUND FRACTURE OF THE
CRANIUM, WITH DEPRESSION AND LACERATION OF THE
BRAIN AND ITS MEMBRANES—PERFECT RECOVERY.

Case 1.—On the 16th of June, 1862, I was called upon to see a young man, named Patrick Connor, aged 20 years, who, I was informed, had received a gunshot wound of the skull by the accidental bursting of a gun.

The history of the case is briefly this:—He took out a gun to shoot at some crows that were eating his father's potatoes; the gun burst, and one of the fragments struck him on the left side of the head, fracturing his skull about the junction of the frontal and parietal bones.

The account which I received from a person who witnessed the accident was: that after he had been knocked down, he made three attempts to get up, but each time without success; the fourth time, however, he succeeded in getting on his feet, and putting his hand on the wound in his head, he commenced running, or rather staggering at first, as if he were under the influence of drink, running more steadily as he proceeded, until he came to the first ditch, which he cleared in a bound; in this way, going at the top of his speed, he jumped five large ditches, until he arrived at the house of his sister (a distance of 120 Irish perches), where he immediately fell inside the door.

When I saw him, he was lying in bed, breathing heavily (not stertorously) very much disfigured with blood, which I washed off, and then saw the frightful character of the accident with which I had to deal. A large, irregular, lacerated wound, from which the blood came welling up, and on raising one of the flaps, I found it coming from one of the branches of the middle meningeal artery, which had been torn across.

I succeeded in stopping the hæmorrhage by very slight pressure of the finger on the artery against the edge of the undepressed bone. When the bleeding had stopped, I could see several small pieces of bone lying on the brain, at the bottom of the wound. I gently removed them, and one of about an inch in length, which had been driven into the substance of the brain, this I also removed; and whilst doing so, he awoke up with a start, and had an attack of vomiting, accompanied by slight convulsive movements of the muscles of the face.

Immediately after the convulsion had passed away, he relapsed into his former state of insensibility.

The spicula of bone removed was covered with brainy matter.

Whilst shaving his head, I became aware of the fact that a large portion of the parietal bone, about the circumference of a crown piece, had been fractured, and could be felt to move easily beneath the finger.

Having shaved the head, and removed all the loose spicula of bone I could find, without endangering the brain to any further injury, I carefully drew the flaps of the wound together; at this time his stomach again became sick, and I now found that he was partially paralyzed on the opposite side of the body from that injured. Having dressed the wound with a light compress of lint, secured by a loose bandage, and kept constantly wet with cold water, I left, and called again in the evening.

On my return I found that he had not passed water since the accident, neither had his bowels been moved. Having drawn off the urine, and ordered him an aperient draught, I left.

17th: Still perfectly insensible; breathing, which had not been stertorous before, had now become so; pulse 60, and laboured; bowels not being moved by the draught, I ordered him a purgative enema.

18th: Much the same as the day before; bowels still obstinately confined. I ordered him another oil draught,

which he could not, or would not, swallow. I then ordered him another enema, composed of ℥ij. of castor-oil, ℥ij. of oil of turpentine, and ℥viii. of mucilage of starch; he passed water during the night, but is still unconscious; pulse 70, and not so laboured.

At my visit in the evening he was much the same; bowels still unmoved, and breathing stertorously. Upon the whole, I considered him worse than he was when I saw him in the morning.

19th: No better; bowels still obstinately confined. I determined to try croton-oil if they were not moved before evening; pulse much the same, about 70, but not so laboured.

At my visit in the evening, I found his bowels still confined, so I placed a drop of croton oil on the back of his tongue.

20th: At my visit this morning, I found him much better in every respect; bowels opened several times during the night, and passed water freely; pulse 75; could be roused, but could not speak, and became unconscious, immediately afterwards stertorless.

At my evening visit—still better; bowels moved twice during the day; made water freely; pulse 80, and not so laboured; stertor completely gone; easily roused; attempted to speak, and in a very weak voice asked for some drink, but soon became insensible again. The wound in the scalp going on well.

21st: From this date all unfavourable symptoms gradually subsided; I kept him on an unstimulating, though nourishing, diet, with attention to his bowels for some months, until all symptoms of paralysis of both speech and motion had passed away; and in the space of twelve months he was able to resume his trade as a carpenter, at which he now works, without a single bad symptom remaining, and in the enjoyment of perfect health. I have seen him myself, not more than a week past, working in this town.

Balbriggan, August 22nd, 1866.

Hospital Reports.

THE CHOLERA WARDS OF THE HOSPITALS OF LONDON.

A FEW weeks ago we mentioned what might be repeated with equal truth at the present date, that there has been little novelty presented in the cholera wards of the great hospitals of the metropolis.

This, to many, will be a source of regret, for in a disease of so appalling a nature, and so rapid in its progress, the whole profession eagerly watches every variety of treatment adopted by the physicians to the institutions. In the midst of such an outbreak as that which is now happily declining, those immediately engaged are too occupied to make elaborate records. It is, therefore, with peculiar satisfaction we have reported from week to week, and that as briefly as possible, the leading observations that have been made, as well as the various modes of treatment adopted. For more exact particulars we must wait till the conclusion of the epidemic shall leave the requisite leisure to those who have been chiefly occupied. In the meantime, we continue to furnish such details as we collect.

LONDON HOSPITAL.

THERE is still a diminution in the number of cases admitted, corresponding, we hope, to the decrease of the disease, as well as to the temporary hospital we mentioned as having been opened in our last number.

The injections into the veins have again been tried. In one case the subcutaneous injection of water has been tried in the stage of collapse. The patient died.

This treatment was originated by Dr. Beigel, who has occupied himself to a great extent with the hypodermic method, and two of whose cases, at the Metropolitan Free Hospital, we recently reported in these columns.

Admissions into the Cholera Wards of the London Hospital during last Week.

	CHOLERA.		DIARRHŒA.	
	Males.	Females.	Males.	Females.
Aug. 24th .	4	1	3	3
25th .	2	1	1	6
26th and 27th	3	8	6	3
28th .	0	2	1	4
29th .	5	2	0	2
30th .	2	1	0	2
Totals .	16	15	14	22

Since the beginning of the epidemic up to the 30th August, the following table shows the numbers relieved by this hospital:—

	Admissions.	Recoveries.	Deaths.	Remain.
Cholera .	495	177	266	52
Diarrhœa .	184	129	15	40
Totals .	679	306	281	92

Besides these, 9494 minor cases have been treated as out-patients.

GUY'S HOSPITAL.

At this hospital a very melancholy case has occurred, which all the political journals have related. It is that of a man whose whole family has perished. The whole family was in good health on the 22nd; on the 23rd the mother was seized, and died. The two children followed in a few hours. Lastly, the poor man himself was seized, and conveyed to Guy's, where he died in a few hours. This family lived at Bermondsey, and no one else in the neighbourhood was known to have suffered.

It has been stated that some communication between the drinking water cistern and the water-closet has been discovered.

ST. BARTHOLOMEW'S HOSPITAL.

No new cases to report; but we may take the opportunity of stating that the peroxide of hydrogen, reported last week as having been tried, was employed at Mr. Smee's suggestion. The other remedies have been those most generally resorted to.

GERMAN HOSPITAL.

The cases recently admitted have been of a milder type than heretofore, which may perhaps be taken as an encouraging circumstance in reference to the decline of the epidemic, although we feel bound to add that in conversations with the medical men at some of the other hospitals, we have recently been assured that they have not at present noticed any decrease of severity in the symptoms of the new patients.

Observations on the temperature continue to be made at this hospital; and Dr. Weber remarked that in one case there had been a difference of 7° Fahr. between the axilla and the rectum during the collapse, and that in the reaction the difference had fallen to 2°, and this again fell to 1° after convalescence. From this and other cases it would appear that in the stage of collapse the internal temperature is increased in proportion to the diminution of the external.

After the eruption, a well-marked desquamation has occurred at this as well as the London Hospital.

THE CHOLERA HOSPITAL AT ST. GEORGE'S IN THE EAST.

At this Institution a large number of cases have been attended by Dr. Belcher, who has also been greatly occupied with the epidemic in the district to which he is attached. In the milder cases remedies have been efficacious, but in fully developed Asiatic cholera the mortality has been great whatever the treatment adopted. Indeed, Dr. Belcher seems to be of opinion that true Asiatic cholera is simply incurable. There can be no doubt that a separa-

tion of the disease into its varieties materially changes the face of any statistics. We have noticed that at one hospital nearly all the cases are recorded as simply cholera, while at others they are divided in various manners. If we separate only the choleraic diarrhœa, we find it much more amenable to treatment. While on attempting a still further division, as Dr. Belcher has done, with a corresponding change in the remedies, a greater success is attainable. Thus castor-oil or a dose of calomel has been given by Dr. Belcher to a number of cases distinguished by the evacuations being dark and offensive. In others, in which flatulence was particularly distressing, turpentine, oil of cajeput, chloric ether, and other antispasmodics have been useful.

Amongst other remedies tried we may enumerate calomel, tartar emetic, Epsom salts, laudanum, carbonate of ammonia, tincture of capsicum, prussic acid, tincture of aconite, permanganate of potash, and, in fact, all the various drugs that have been recommended.

Many of the worst cases that have come under Dr. Belcher's care have been those of the Irish living in poverty and dirt in a part of the district where there is an accumulation of filth and decaying vegetable matter, to which Mr. James Greenwood, the amateur casual of the *Pall Mall Gazette*, has already publicly drawn attention.

One or two cases of sudden death after the patients seemed doing well have occurred in this hospital, and may serve to point out a danger that must not be overlooked in forming a prognosis. Death seemed to result from syncope, and might perhaps be due to embolism. Some other deaths after convalescence had commenced were preceded by a sensation of great drowsiness, notwithstanding which sleep could not be obtained. It should also be noted that the cholera eruption has been frequently seen in this hospital. This is to be carefully distinguished from purpura or petechiæ, which, when occurring in the reaction, may be looked upon as the precursors of death. The patients at St. George's have had the benefit of the nursing by the Sisters of St. John's mission, who have been by day and night indefatigable in rendering their valuable services.

BELLEISLE HOSPITAL SHIP.

The reports that have been circulated by the daily journals as to the decrease of cholera on the Thames are happily confirmed by the number of admissions to this ship, which have fallen to an average of about one daily, while for six or seven consecutive days no death occurred on board.

About twelve cases have been treated by hypodermic injections of quinine, six of these have terminated fatally. No local mischief has, in any case, resulted from the injections, and Mr. H. Leach thinks the treatment sufficiently encouraging to deserve a further trial.

A remarkable circumstance at this hospital is the rapidity of convalescence. On the average the patients only stay four days in hospital. We might anticipate that the sailors, as a class, are very hardy men, and would naturally recover with proportionate rapidity, but certainly this is beyond our expectations.

In connexion with this point it may be worth while to consider whether, when the room is not required for fresh cases, it might not be desirable to prolong the patient's stay in hospital, or which would be far better—provide another ship for the convalescents.

On this point, the reply of Dr. Andrew Clark, of the London Hospital, to a question of the Bishop of London, at the Mansion House, is most important. Dr. Clark declared there was no disease, except scarlatina, which sowed more of the seeds of functional disease than cholera. Though cholera patients seemed to recover rapidly, there was still an immediate risk of the disease, with even the appearance of health. Speaking with all the authority of his experience, Dr. Clark maintained that true convalescence from cholera was always tardy, and often very dangerous, and therefore he supported a proposition for the Mansion House Committee, of which he is a member, to

make some special provision for the temporary relief of convalescents. We must say that, in face of such an opinion, it would be well to persuade, even so hardy a class of men as sailors proverbially are, not to leave the hospital too soon. Indeed, should Dr. Andrew Clark's idea prove correct, it would be not only better for the patients, but much safer for their friends for them to delay their return.

LIMEHOUSE DISTRICT CHOLERA HOSPITAL.

DURING the week the admissions have been raised to 122 of cholera, and 18 diarrhœa. Of these, 40 patients from cholera, and 1 from diarrhœa, have died. 60 persons, who suffered from cholera, and 10 from diarrhœa, have been discharged cured. Of the deaths, 31 took place in the cold stage, 9 in that of reaction. One patient died in 12 hours from the first seizure; one survived 11 days, and then died. A variety of methods of treatment have been adopted by Drs. Woodman and Heckford, who have charge of the hospital, but it is at present too early to make comparisons. The total mortality, being only 33 per cent., is certainly satisfactory.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

SUPERFICIAL EMPHYSEMA: TWO FORMS OF.

THE occurrence of emphysema in the superficial parts of the body, independently of fracture of a rib or other surgical injury, is an affection sufficiently rare to merit notice, and has been well illustrated in its graver complications by some cases which have presented themselves in Dr. Lyons's practice in hospital and in private.

Emphysema in the Course of Measles.—In this instance the patient, a very fine young girl, about 19 years of age, and previously in good health, was attacked with measles. From the first the disease assumed a serious aspect; the eruption was superabundant and of livid hue; the bronchial affection extreme, and the cough most distressing by day and night. About the fifth day of the disease, a new condition was found to have been superadded; the surface of the trunk from the clavicles down, including the entire front of the chest, abdomen, sides, and part of the back, were found to be universally crepitant. This condition was first noticed on placing the stethoscope under the right clavicle, and the incident is worth being borne in mind as a possible source of error in diagnosis. A fine prolonged crepitus was at once audible when the stethoscope was placed under the collar bone. If a hasty conclusion had been formed, the idea of a suddenly developed localized tuberculosis of the lung might have been entertained, and neither the family history of the patient, nor the possible pathological eventualities of such a case, would have been opposed to the occurrence of such a lesion. The most careful examination was at once made of all parts of the surface, when the presence of a general state of subcutaneous emphysema was at once recognized. The discovery of such a state did not, however, leave the case free from the gravest apprehensions for its ultimate issue. If, as observed by Dr. Lyons, the emphysematous condition is allowed to proceed to an extreme degree, it complicates much the patient's chance of safety, and may even prove the cause of a fatal termination. This has been well exemplified in the records of the interesting case detailed by Dr. Ireland of this city, nearly fifty years ago, in which emphysema, occurring in a child, proved fatal by its rapid extension, reaching the head ultimately, and producing great unilateral deformity, with, it is to be presumed, pressure on the parts within, and consequent loss of life.

In the case under consideration, the emphysematous state was limited by the line of the clavicles above, and was gradually lost as the hand was passed over the lower

part of the abdomen and flanks. It did not at any time extend into the neck or reach the extremities. After some days of much anxiety, the patient gradually began to show signs of amendment, and ultimately convalescence was established; but some weeks elapsed before the final disappearance of all emphysematous crackling, of which the patient herself was quite cognizant.

Emphysema in Whooping Cough.—This complication is already sufficiently known to the practical physician.

Universal Superficial Emphysema as a complication of Chronic Bronchitis and Emphysema of the Lung.—The patient, J. C., aged 55, a tin-worker, of very cachectic aspect, suffering much at times from cough and bronchial irritation, but not otherwise presumed to be in ill-health, was suddenly attacked at night with cough, pain, and sense of distress. Having drunk some porter before retiring to bed, he appears not to have been himself quite conscious of what took place; but his wife stated that he suddenly woke with a scream. At daylight it was found that his face, neck, body, and the limbs partially were much distorted in shape; the swelling was rapidly advancing, and he was admitted to Jervis-street Hospital. When seen at the morning visit by Dr. Lyons, nearly all parts of the body were found to be emphysematous; the neck and one side of the face were swollen to enormous dimensions; the left eye was completely closed from the distension of the lids; the cheeks were puffed out to a hideous degree; and the effusion of air was rapidly increasing. Between eleven a.m. and one p.m. the right eye had become closed; the whole head was now at least twice its natural volume, and with the great lateral width of the face, and the distension of the neck, the whole aspect of the countenance was so altered that it would have been almost impossible to recognize it as that of a human being. The supra and infra-clavicular, as well as the mammary regions, were puffed out in great convex masses, and gave a loudly tympanitic sound on percussion. The emphysematous swelling could be traced all down the trunk, both before and behind, and down the extremities, both upper and lower, to the fingers and toes. The thighs were loudly resonant on percussion, and a drum-like sound could be elicited from almost any portion of the trunk or extremities when percussed. As it was evident that the effusion of air was rapidly spreading, and, from the distress experienced by the patient, that life was imminently threatened, it was determined by Dr. Lyons, after consultation with several of the eminent Surgeons of the Institution, whom he had then the honour to call his colleagues, to give exit by free puncture to the imprisoned air. Accordingly, with the assistance of his friend, Dr. Forrest, Dr. Lyons proceeded to make numerous punctures with a glover's needle on the anterior part of the chest, but this being found to give exit to the air but slowly, recourse was had to the lancet. Some dozen free apertures were thus made, and the air escaped rapidly. On the first few punctures being made, the air was driven out with great force, impinging on the operator's nose, and the opportunity was thus fully afforded of testing the character of the air. It was, in all sensible respects, like atmospheric air, and free from all smell whatever. From the apertures thus provided, and which were confined to the anterior parts of the chest, the imprisoned air continued to escape abundantly, and in the course of about two hours, the patient was enabled to open both his eyes, and expressed himself immensely relieved.

It is unnecessary to follow the daily history of the case. The swelling gradually subsided; all means were taken to check the cough, the patient lending himself readily to the assistance of art by voluntarily controlling efforts at cough, which it was explained to him would have the effect of increasing the effusion of air by forcible distension of the injured lung substance. It required, in all, more than six weeks before the patient was enabled to leave hospital; the femoral tympany continued for a protracted period; and when ultimately sufficiently recovered to leave hospital, it was noticed that he still retained a very cachectic aspect.

In about three months subsequently he sought admission into the Whitworth Hospital, and was again taken under Dr. Lyons's care in this institution. He was found to be labouring under ascites to an extreme degree, and had all the appearance and physical evidences of advanced malignant disease of the liver. He sank after about six weeks sojourn in hospital, and on post-mortem examination it was found that the liver was in a peculiar condition of mixed cirrhosis and general cancerous degeneration. The lungs were found to be partially emphysematous, with evidence of old bronchitis, but no trace could be found of the lesion by which air had escaped from the lung into the areolar tissue of the mediastinum, and thence through the body generally. It was put beyond question, as the result of post-mortem examination, that there had been no fracture of a rib at the period of occurrence of the emphysematous state above described.

Emphysema during Parturition.—The occasional occurrence of this condition as the result of violent respiratory efforts during labour is well known to obstetric practitioners. It is but rarely a grave complication.

Superficial Emphysema in Cholera.—It may be worth while to call to mind, in the presence of another visitation of cholera, the observations formerly recorded by Dr. Lyons as to the association of a general emphysematous state of the body with cholera. This singular phenomenon was usually presented in the course of convalescence from cholera. It occurred, in numerous instances of cholera cases amongst the French troops during the Crimean war. The integuments of the abdomen were observed to be in a sort of doughy state, and showed by well-marked crepitus on examination by the fingers the presence of air in the areolar tissue over a considerable extent of surface. Though it can hardly be considered as the cause of this phenomenon, it may be mentioned that while in the stage of collapse the patients in question had been submitted to the action of the moist warm vapour of the inner chamber of the Turkish bath, appropriate stimulation, with frictions of the surface, being employed at the same time. In one instance, at least, this singular emphysematous condition supervened almost immediately on the exposure of the patient to the influences of the heated vapour. In most cases this condition gradually disappeared, the air or gas seeming to undergo a progressive absorption.

Emphysema in Connexion with Fatty Heart.—As a post-mortem condition this form of emphysema is known to occur in certain cases.

Emphysema in Connexion with Gangrene.—As the sequence of gunshot wound or surgical operation, Dr. Lyons has described a state of general gaseous distension of nearly all the tissues of body occurring in certain cases of gangrene. The most noticeable features of the condition appear to be:—Death of the parts more immediately concerned in the injury or operation; gaseous distension of the limb; a more or less general emphysema of other parts of the body; an almost total disappearance of the blood and its replacement in the heart and vessels by gas; advanced decomposition of the viscera of the chest and abdomen. It was remarkable that the various organs and tissues did not present the appearance of being merely dead and spontaneously undergoing decomposition, as in ordinary cases, but they seemed to show in the changes so rapidly and intensely produced the effects of a peculiarly destructive agency. The explanation of this agency is probably, Dr. Lyons thinks, to be sought in the sudden, and, as it were, explosive decomposition of the circulating fluid, its chemical constituents assuming the gaseous form in a sudden and violent manner, and the resulting gases in their expansion, causing a mechanical separation and disintegration of the particles of the tissues.

Emphysema in Connexion with Cattle Plague.—The occurrence of this condition may be referred to to complete the notice of the chief forms in which this phenomenon of gaseous distension of the animal tissues is known to occur before and after death; but the further discussion of this state is out of place here.

THE CHANGE OF TYPE IN DISEASES.

No apology can be necessary in a Medical Journal for ventilating the question as to the existence or non-existence of a change of type in diseases in successive epochs in human history. The question is not merely a hypothetical one, the truth or falsehood of which is a matter of utter indifference to the majority of mankind; but it is one of primary and pressing interest to every household and to every individual, inasmuch as a correct or incorrect judgment in a critical case may lead to the most important results to families and even to nations. Within our own times we have heard of great statesmen, who appeared to sway the destinies of empires, being hurried away from this breathing and living world by what has been considered the injudicious employment of bloodletting, and on the other hand, the British nation still deplors the loss of one still dear to memory, who certainly never was bled at all, but who, if he had been treated by some of our Continental medical brethren, would probably have been subjected to that method of depletion.

It is a well known fact that some thirty or forty years ago, it was the fashion to treat fevers and inflammations by the abstraction of blood and by other depletory measures, and according to the evidence of the Medical practitioners of that period, the plan was attended with success. But since the invasion of cholera in 1832, and of influenza in 1833, the depletory plan has been discountenanced, and, in very many instances, wholly abandoned; and for this change of treatment two entirely different reasons have been assigned, one being that disease has changed its type at or about the period to which we refer, and the other, that the practitioners before 1832 were utterly wrong in their notions as to the treatment of disease, and that those who practised since that period have been entirely right.

Now, in a case like this, every one must speak and write for himself, and those who, in face of the epidemics of 1832 and 1833, persisted in bleeding and purging their patients in spite of the ill-effects which followed such treatment, must, of course, answer for their misdeeds; but as for ourselves who happen to recollect the epidemics in question, we have no compunctious visitations on that score, because, as far as our experience goes, the depletory system was promptly abandoned as soon as it was found to be unsuccessful and inexpedient. That cholera and influenza did not bear bleeding and purging we freely allow, but we assert that this truth was well known to those who practised at that period, and who, in presence of diseases till that time unknown in an epidemic form in Europe, immediately relinquished this course of treatment as soon as

it was found to be unsatisfactory. It would have been too much to expect that the practitioners and students of that time should at once have abandoned the plans of treatment recommended in all their text books, and we deem it was a sufficient merit on their parts to examine for themselves the practical efficiency of the system then laid down for their guidance, and to give it up when they found it unsuccessful. Let any one examine the books published on "Medicine" between the years 1822 and 1832, and let him inform us as to the then existing knowledge as to the treatment of Asiatic cholera and epidemic influenza, and we shall be happy to record the facts as a matter of medical history; and we may further ask for any definite account of the nature and symptoms and treatment of epidemic diphtheria before the publication of the New Sydenham Society's volume on that subject, edited by Dr. SEMPLE in 1859. We do not positively allege that Asiatic cholera, and epidemic influenza, and epidemic diphtheria, are absolutely new diseases in this country. All we assert is, that British practitioners in general were not acquainted with Asiatic cholera in England before 1832, with epidemic influenza before 1833, or epidemic diphtheria before 1859. But it may be asked what all this has to do with the theory of change of type in disease? Even admitting that cholera, and epidemic influenza, and epidemic diphtheria, have been only comparatively lately introduced into this country, how does the circumstance prove a change in the type of diseases in general? It is the diseases themselves which have changed and not their type. This is perfectly true, and yet on comparing a record of patients in some great hospital for a year, say in 1820, with another similar annual record in 1860, will it not be found that in the former period there was more inflammatory croup, more sthenic pneumonia, phrenitis, congestion of the brain, &c., while in the latter period there was more neuralgia, more influenza and diphtheria, and other diseases known to be of an asthenic character? Although, therefore, it may be true that the diseases themselves are different, yet the predominance of the asthenic diseases over the sthenic ones surely proves that disease in general may be of a different character at one period than at another, or at one locality as compared with another.
